Adaptive Robust Control for Networked Strict-Feedback Nonlinear Systems with State and Input Quantization

Yanbin Liu 1, Jue Wang 1, Luis Gomes 2,* and Weichao Sun 1

Abstract: Backstepping method is a successful approach to deal with the systems in strict-feedback form. However, for networked control systems, the discontinuous virtual law caused by state quantization introduces huge challenges for its applicability. In this article, a quantized adaptive robust control approach in backstepping framework is developed in this article for networked strict-feedback nonlinear systems with both state and input quantization. In order to prove the efficiency of the designed control scheme, a novel form of Lyapunov candidate function was constructed in the process of analyzing the stability, which is applicable for the systems with nondifferentiable virtual control law. In particular, the state and input quantizers can be in any form as long as they meet the sector-bound condition. The theoretic result shows that the tracking error is determined by the pregiven constants and quantization errors, which are also verified by the simulation results.

Keywords: state and input quantization; networked control systems; uncertain systems; nonlinear systems; adaptive robust control

1. Introduction

Nonlinear systems in parametric strict-feedback form with uncertainties have been investigated a lot due to their widespread applications in modeling real systems, such as chaotic systems, robot/manipulator systems, vehicle systems and so on [1–4]. The backstepping method, proposed by Petar V. Kokotovic in [5] in 1992, is a successful way to deal with the systems in strict-feedback form. Under this method, the plant can be divided into a variety of subsystems by introducing virtual control inputs, and then, a step-by-step controller is designed for the plant. As for system uncertainties that are inevitable in real systems, there are two sorts of classical schemes to design the controller, i.e., adaptive control (AC, [6]) and deterministic robust control (DRC, see [7]). These two control laws have their own advantages and disadvantages: under the AC method, the closed-loop system is asymptotically stable in the existence of uncertain parameters only, but it may lead to instability when there is disturbance; under the DRC method, uniform ultimate boundedness (UUB) is guaranteed in the case of both uncertain parameters and disturbance. In [8], adaptive robust control (ARC) was proposed by Bin Yao and Masayoshi Tomizuka, which combined the advantages of both AC and DRC. That is, not only is the UUB property guaranteed when the system is under uncertain parameters and disturbance, but also the asymptotic stability is guaranteed under the uncertain parameters only. Just about these good properties of ARC, it has been widely applied in many engineering systems [9–11].

In modern society, networked control systems have been widespread investigated due to their own benefits such as low installation and maintenance cost, strong anti-interference capability of the signal, easily encrypting, storing or processing and so on. These benefits give a great impetus to develop and expand its application fields, especially in power systems, vehicle industry, teleoperation and network-based process control engineering [12,13].
However, the traditional backstepping method is hard to apply to systems in strict-feedback form for the reason that in such a system, the signal transmission between controller and plant is achieved via a digital communication network (see Figure 1), which may draw into various problems, such as time delays (deterministic delays and stochastic delays, [14]), sampling [15], packet losses (off-line algorithm [16] and on-line algorithm [17]) or packet disorder [18] and signal quantization [19]. For parametric strict-feedback nonlinear systems, some of these issues have been solved well in the past few years. In [20], the time-delay problem was considered and dealt with via adaptive NN backstepping control; while in [21], the Lemma 1 solved the sampling problem, and an adaptive sampled-data control scheme was designed for a certain class of nonlinear systems. The packet losses and time delay were considered by Wang et al. in [16].

![Figure 1. The signal transmission in networked control systems.](image)

Although there have been many results for networked control systems in strict-feedback form, few results aim at signal quantization, especially state quantization [22–24]. In the past decades, input quantization has been widely concerned. In [25], $L_1$ adaptive controller was put forward for a class of uncertain nonlinear system. Jing Zhou et al. designed an adaptive backstepping controller for a class of strict feedback system with quantized input signals in [26]. After that, Lantao Xing et al. further investigated the output feedback problem of systems in strict feedback form and proposed an adaptive output-feedback control scheme in [27]. Moreover, in [28], a control method based on set-valued map was presented for nonlinear systems in strict-feedback form with quantized states. However, the complexity of this method restricts its application. In addition, it may be inapplicable when there are external disturbances. In a word, it is quite necessary to propose a universal method to deal with state and input quantization problems of strict-feedback systems.

This paper focuses on a class of uncertain nonlinear systems in strict feedback form with quantized states and input feedback. An ARC law is designed for concerned systems to ensure stability and tracking performance. The main contributions are summarized as follows: Firstly, we construct a novel differentiable and positive definite Lyapunov candidate function $V(t)$ via the states of the plant and the nondifferentiable virtual control law. Then, based on the backstepping method and the proposed Lyapunov candidate function, the detailed design processes of the ARC law are given in a step-by-step way. The analysis illustrates that under the designed controller, the closed-loop system is UUB in spite of the high uncertainties and quantized errors. To verify the universality of our results, in the simulation part, we employ both uniform quantizers and logarithmic quantizers for signal quantization. Moreover, both the stability and tracking problems are considered in simulation.
This paper is organized as follows: In Section 2, the sector boundary condition is introduced and the problem formulation is illustrated. The ARC scheme based on backstepping method is designed in Section 3 for the uncertain nonlinear systems in parameter strict-feedback form with state and input quantization. The simulation part follows in Section 4, which verifies the theoretical result above. Finally, the conclusion is given in Section 5.

**Notation 1.** \(\mathbb{R}\) represents the field of real numbers. \(\bullet, \bullet, \ldots, \bullet^{(n)}\) denote for the first-order, second-order, \(\cdots\), and nth-order derivative of \(\bullet\) with respect to time \(t\). \(\xi_i = [\xi_{i1}, \xi_{i2}, \ldots, \xi_{in}]\). \(\|\bullet\|\) represents the Frobenius norm of a matrix \(B\) or Euclidean norm of a vector \(\xi\), i.e., \(\|B\| = \sqrt{\sum_{i,j} b_{ij}^2}\) and \(\|\xi\| = \sqrt{\sum_{i} \xi_i^2}\). \(B^T\) denotes the transposition of \(B\).

### 2. Problem Statement

Without loss of generality, consider the following SISO nonlinear system with uncertain parameters and disturbances:

\[
\begin{aligned}
\dot{x}_i &= \varphi_i^T(x_i, t)\theta + x_{i+1} + D_i, \quad i = 1, 2, \cdots, n - 1, \\
\dot{x}_n &= \varphi_n^T(x_n, t)\theta + u_q + D_n, \\
y &= x_1,
\end{aligned}
\]

where \(x_1, x_2, \cdots, x_n \in \mathbb{R}\) are the states of the system; \(x_i = [x_{i1}, x_{i2}, \cdots, x_{in}]^T\); \(\theta = [\theta_1, \theta_2, \cdots, \theta_p]^T\); \(\theta_i \in \mathbb{R}\) are the unknown parameters; for \(i = 1, 2, \cdots, n\), \(\varphi_i = \varphi_i(x_i, t): \mathbb{R}^i \times \mathbb{R} \to \mathbb{R}^p\) are all known function vectors; \(D_i \in \mathbb{R}\) are the unknown functions representing the time-varying disturbances and the unmodeled dynamics; \(y \in \mathbb{R}\) and \(u_q = Q_u(u) \in \mathbb{R}\) are the output and quantized input, respectively; \(u = u(t, x_{i1}) \in \mathbb{R}\) is the quantized states feedback controller and \(x_{i1} = Q_i(x_i)\) are the quantized states. Actually, the result in this paper can be easily generalized to the case that \(x_i\) are all \(m\)-dimensional vectors.

For the requirement of later analysis, the following conditions are assumed on the plant:

**Assumption 1.** The uncertain parameters \(\theta_i\) and unknown functions \(D_i, i = 1, 2, \cdots, n\) are all bounded, i.e.,

\[
\theta_i \in [\theta_{i_{\text{min}}}, \theta_{i_{\text{max}}}] = \Omega_i, \quad |D_i| \leq d_i,
\]

where \(\theta_{i_{\text{min}}}\) and \(\theta_{i_{\text{max}}}\) are the lower and upper bound of \(\theta_i\); \(d_i\) are the boundary of the unknown function \(D_i\). Denote \(\Omega_{\theta} = \{\theta : \theta_i \in \Omega_i\}\); \(\theta_{\text{max}} = [\theta_{1_{\text{max}}}, \cdots, \theta_{p_{\text{max}}}]^T\); \(\theta_{\text{min}} = [\theta_{1_{\text{min}}}, \cdots, \theta_{p_{\text{min}}}]^T\); and \(\theta_m = \max(|\theta_{i_{\text{max}}}|, |\theta_{i_{\text{min}}}|)\).

**Assumption 2.** For all \(i = 1, 2, \cdots, n\) and \(x_i, \varphi_i(x_i, t)\) is continuous differentiable up to order \(n - i\) with respect to \(x_j, j = 1, 2, \cdots, i\) and \(t\). Moreover, \(\frac{\partial^n \varphi_i}{\partial x_j^n}\) satisfy the Lipschitz condition with respect to \(\tilde{x}_i\).

**Assumption 3.** The reference command \(r \in \mathbb{R}\) is sufficiently smooth.

**Assumption 4.** The sector boundary condition holds for both state and input quantization, i.e., for \(i = 1, 2, \cdots, n\) and \(j = 1, 2, \cdots, m\), there exist constant \(0 \leq \delta_u < 1, 0 \leq \delta_{x_i} < 1, \omega_u \geq 0\) and \(\omega_{x_i} \geq 0\) such that

\[
\begin{aligned}
|\Delta_u| &= |u - Q_u(u)| \leq \delta_u |u| + (1 - \delta_u) \omega_u, \\
|\Delta_{x_i}| &= |x_i - Q_{x_i}(x_i)| \leq \delta_{x_i} |x_i| + (1 - \delta_{x_i}) \omega_{x_i}.
\end{aligned}
\]
Denote $\bar{\Delta}x_n = [\Delta x_1, \cdots, \Delta x_n]^T$ and from (3), we have

$$\|\bar{\Delta}x_n\| \leq \delta_{\text{max}} \|x_n\| + \varpi_{\text{max}},$$

where $\delta_{\text{max}} = \max_i \{\delta x_i\}$ and $\varpi_{\text{max}} = \max_i \{(1 - \delta x_i)\varpi x_i\}$.

**Remark 1.** It should be noted that most common quantizers meet the sector bound property (3), such as uniform quantizer (in [29]), logarithmic quantizer (in [25]), hysteresis quantizer (in [26]) and compound quantizer (in [27]). The uniform quantizer and logarithmic quantizer are listed below as two typical examples.

A. Uniform quantizer:

There are various kinds of uniform quantizers in previous papers. We introduce the midriser uniform quantizer as an example in this paper (see also in [29]).

$$Q(\xi) = \varpi \left(\left\lfloor \frac{\xi}{\varpi} \right\rfloor + \frac{1}{2} \right)$$

where the notation $\lfloor \cdot \rfloor$ depicts the floor function and $\varpi > 0$ is a known constant that determines the quantization density. The figure of the uniform quantizer (5) is shown in Figure 2. The quantization error of (5) satisfies

$$|Q(\xi) - \xi| \leq \frac{\varpi}{2},$$

which means that the sector boundary condition (3) is true with $\delta = 0$.

B. Logarithmic quantizer:

![Figure 2. Diagram of the uniform quantization.](image-url)
As another example, the logarithmic quantizer modeled as below is considered, whose diagram is shown in Figure 3 [25].

\[
Q(\xi) = \begin{cases} 
\xi_i & \frac{\xi_i}{1+\delta} < \xi \leq \frac{\xi_i}{1-\delta} \\
0 & 0 \leq \xi \leq \frac{\omega}{1+\delta} \\
-Q(-\xi) & \xi < 0.
\end{cases}
\]  

(7)

where \( \xi_i = \rho^{-1}\omega, \ i = 1, 2 \cdots, \omega > 0 \) and \( \rho = \frac{1+\delta}{1-\delta} \). The quantization error is

\[
|Q(\xi) - \xi| \leq \min\left(\frac{\omega}{1+\delta}, \frac{\xi_i}{1-\delta} - \xi_i\right) \leq \delta|\xi| + \frac{\omega}{1+\delta}.
\]  

(8)

That is, the inequality (3) is true.

Figure 3. Diagram of the logarithmic quantization.

Under Assumptions 1–4, the control objective is to design an adaptive robust controller for the uncertain nonlinear system (1) such that all the signals of closed-loop system are bounded and the output \( y(t) \) tracks the reference command \( r(t) \) with the states and inputs quantized by quantizers.

3. Main Results

3.1. Backstepping Based Arc with Quantized States

In this section, treating the quantized errors of state signal as unmodeled dynamics, we propose an adaptive robust controller based on backstepping method for the plant (1) with state quantization only. First of all, the following lemma is necessary for the subsequent analysis.
Lemma 1. For \( i = 1, 2, \ldots, n \) and any bounded set \( \Omega \subset \mathbb{R}^1 \), \( \phi^{(j_1, \ldots, j_i)}_i(x, t) = \frac{\partial^i \phi_i}{\partial x_1^{i-j_i}} \) satisfies Lipschitz condition in \( \Omega \) with respect to \( s_i \) where \( j_1, \ldots, j_i \in \mathbb{N}^+ \) and \( j_1 + \cdots + j_i \leq n - i \), i.e., there exists a constant \( \mathcal{L}_{j_1, \ldots, j_i} \Omega > 0 \) such that for all \( \xi_1, \xi_2 \in \Omega \),
\[
\left| \phi^{(j_1, \ldots, j_i)}_i(\xi_1, t) - \phi^{(j_1, \ldots, j_i)}_i(\xi_2, t) \right| \leq \mathcal{L}_{j_1, \ldots, j_i} \Omega \| \xi_1 - \xi_2 \|.
\] (9)

Proof. From Assumption 2, the lemma is true when \( j_1 + \cdots + j_i = n - i \). For any \( j = 1, 2, \ldots, i \) and \( j_1 + \cdots + j_i < n - i \), \( \phi^{(j_1, \ldots, j_i)}_i \) is continuous differentiable with respect to \( x_j \). Therefore, \( \frac{\partial \phi^{(j_1, \ldots, j_i)}_i}{\partial x_j} \) is continuous and bounded in the set \( \Omega \). That is to say, \( \phi^{(j_1, \ldots, j_i)}_i \) satisfies Lipschitz condition in \( \Omega \) with respect to \( x_j \). This leads to (9). \( \square \)

Following notations are necessary for the convenience of writing.
\[
\begin{align*}
\phi_i &= \phi_i - \sum_{j=1}^{i-1} \frac{\partial}{\partial x_j} \phi_{ji}, \\
\phi_{ji} &= \phi_i - \phi_{qj}, \\
\mathcal{D}_i &= D_i - \sum_{j=1}^{i-1} \frac{\partial}{\partial x_j} D_{ji}, \\
\beta_i &= \int_0^t \left[ \frac{\partial \phi_i}{\partial t} + \sum_{j=1}^i \frac{\partial}{\partial x_j} (\phi_{ji} \phi_{qj} + D_{ji}) + \frac{\partial \phi_{qj}}{\partial t} \right] dt, \\
\tau_i &= \sum_{j=1}^i \phi_{ji} \phi_{qj}, \\
\xi_i &= x_i - \beta_i - 1, \\
\hat{\xi}_i &= x_i - \alpha_i - 1,
\end{align*}
\]
where \( \alpha = r(t) \) and \( \alpha_i \), \( i \geq 1 \) is the virtual control law which are designed later; \( \theta \) is the estimation value of \( \theta \). Subsequently, the design procedures are given below.

Step 1: Consider the first equation of (1). The derivative of \( z_1 \) is given by
\[
\dot{z}_1 = \phi_1^T \theta + x_2 + D_1 - r.
\] (10)

Regard \( x_2 \) as a virtual input, and design for it a virtual control law \( \alpha_1(x_1, \hat{\theta}_1, t) \),
\[
\alpha_1(x_1, \hat{\theta}_1, t) = -k_1 z_1 - \phi_{q1}^T \hat{\theta}_1 + r - \frac{1}{4\epsilon_1} h_1^2 z_1
\] (11)
where \( k_1 > 0; \epsilon_1 > 0; \hat{\theta}_1 = \pi(\hat{\theta}) = [\pi_1(\hat{\theta}_1), \ldots, \pi_p(\hat{\theta}_p)]^T \) is the smooth projection mapping vector with bounded derivatives up to order \( n - 1 \) such that
\[
\begin{align*}
\pi(\hat{\theta}) &= \hat{\theta}, & \forall \hat{\theta} \in \Omega_{\theta}, \\
\pi(\hat{\theta}) &= \Omega_{\hat{\theta}}, & \forall \hat{\theta} \in \mathbb{R}^p;
\end{align*}
\] (12)
where \( \Omega_{\theta} = \{ \psi \in \mathbb{R}^p : \theta_{\min} - \epsilon_{\theta} \leq \psi \leq \theta_{\max} + \epsilon_{\theta} \} \), and \( \epsilon_{\theta} > 0 \) is a small constant. Refer to [8], \( h_1 = h_1(z_1, \hat{\theta}_1, t) \) can be chosen as an any sufficiently smooth function such that
\[
\begin{align*}
h_1 \geq & \| \phi_{q1} \| \| (\theta_{\max} - \theta_{\min} + 2 \epsilon_{\theta}) \| + | D_1 | + (k_1 + \mathcal{L}_{\phi_i} \theta_{\min}) | \Delta x_1 | \\
\geq & \| \phi_{q1} \| | \hat{\theta}_1 | + | D_1 | + | k_1 \Delta x_1 | + | \phi_{q1} \| \theta,
\end{align*}
\] (13)
where \( \epsilon_{\theta} = [\epsilon_{\theta_1}, \ldots, \epsilon_{\theta_p}]^T ; \hat{\theta}_1 = \hat{\theta}_1 - \theta ; \mathcal{L}_{\phi_i} \) is the Lipschitz constant of \( \phi_i \).

From Lemma 1 and Assumptions 1–3, the following lemma can be obtained spontaneously.

Lemma 2. \( \alpha_1, \frac{\partial \alpha_1}{\partial x_1}, \frac{\partial \alpha_1}{\partial \theta} \) and \( \frac{\partial \alpha_1}{\partial \theta} \) satisfy the Lipschitz condition with respect to \( x_1 \).
Consider the positive definite continuous function $V_1 = \frac{1}{2}z_1^2$. From (10) to (13), the derivative of $V_1$ is

$$
\dot{V}_1 = z_1(k_1\Delta x_1 + D_1 - \phi_{q1}^T \hat{\theta}_\pi + \phi_{\hat{\theta}}^T \theta - \frac{1}{4\epsilon_1}h_1^2 z_1) + z_1z_2 - k_1z_1^2 + z_1(\beta_1 - \alpha_1) + \frac{1}{4\epsilon_1}h_1^2 \Delta x_1
$$

(14)

\[ \leq z_1z_2 - k_1z_1^2 + z_1(\beta_1 - \alpha_1) + \frac{1}{4\epsilon_1}h_1^2 \Delta x_1 + \epsilon_1. \]

**Step 2:** Consider the second equation of (1). The derivative of $z_2$ is given by

$$
\dot{z}_2 = \phi_2^T \theta + x_3 + \hat{D}_2 - \frac{\partial \alpha_1}{\partial t} - \frac{\partial \alpha_1}{\partial \hat{\theta}} \dot{\hat{\theta}} - \frac{\partial \alpha_1}{\partial x_{q1}} x_{q2}.
$$

(15)

Regard $x_3$ as a virtual input, and design for it a virtual control law $\alpha_2(x_{q2}, \hat{\theta}_\pi, t)$,

$$
\alpha_2 = -k_2z_{q2} - z_q - \phi_{q2}^T \hat{\theta}_\pi + \frac{\partial \alpha_1}{\partial t} + \frac{\partial \alpha_1}{\partial x_{q1}} x_{q2} + \frac{\partial \alpha_1}{\partial \hat{\theta}} \gamma_{q2} - \frac{1}{4\epsilon_2}h_2^2 z_{q2},
$$

(16)

where $k_2 > 0; \epsilon_2 > 0; \gamma = \text{diag}(\gamma_1, \ldots, \gamma_p) > 0$. From Lemma 2 and Assumption 2, $\phi_2$ satisfies the Lipschitz condition. Thus, $h_2 = h_2(x_{q2}, \hat{\theta}_\pi, t)$ can be chosen as a sufficiently smooth function such that

$$
h_2 \geq |\phi_{q2}^T \hat{\theta}_\pi| + |\hat{D}_2| + |k_2 \Delta x_2| + |\Delta x_1| + |\phi_{q2}^T \theta|.
$$

(17)

**Lemma 3.** $\alpha_2, \frac{\partial \alpha_2}{\partial x_{q2}}, \frac{\partial \alpha_2}{\partial \hat{\theta}}$ and $\frac{\partial \alpha_2}{\partial \hat{\theta}}$ satisfy the Lipschitz condition with respect to $x_{q2}$.

Consider the positive definite continuous function $V_2 = V_1 + \frac{1}{2}z_2^2$. From (14)–(17), the derivative of $V_2$ satisfies

$$
\dot{V}_2 \leq z_2 z_3 - k_1 z_1^2 - k_2 z_2^2 + \epsilon_1 + \epsilon_2 + z_1(\beta_1 - \alpha_1 + \frac{1}{4\epsilon_1}h_1^2 \Delta x_1)
$$

(18)

$$
+ z_2(\beta_2 - \alpha_2 + \frac{1}{4\epsilon_2}h_2^2 \Delta x_2) + z_2 \frac{\partial \alpha_1}{\partial \hat{\theta}} (\gamma_{q2} - \dot{\hat{\theta}}).
$$

**Step i ($2 < i < n$):** Consider the $i$th equation of (1). Take the derivative of $z_i$ with respect to $t$, and we obtain

$$
\dot{z}_i = \phi_{qi}^T \theta + x_{i+1} + \hat{D}_i - \frac{\partial \alpha_i-1}{\partial t} - \frac{\partial \alpha_i-1}{\partial \hat{\theta}} \dot{\hat{\theta}} - \sum_{j=1}^{i-1} \frac{\partial \alpha_{i-1}}{\partial x_{qi}} x_{qj+1}.
$$

(19)

Regard $x_{i+1}$ as a virtual control input and design for it a virtual control law $\alpha_i(x_{qi}, \hat{\theta}_\pi, t)$ as follows,

$$
\alpha_i = -k_i z_{qi} - z_{qi-1} - \phi_{qi}^T \hat{\theta}_\pi + \sum_{j=1}^{i-1} \frac{\partial \alpha_{i-1}}{\partial x_{qi}} x_{qj+1} + \left( \sum_{j=1}^{i-1} \frac{\partial \alpha_{i-1}}{\partial \hat{\theta}} z_{qj+1} \right) \gamma_{qi}
$$

$$
+ \frac{\partial \alpha_i-1}{\partial t} + \frac{\partial \alpha_i-1}{\partial \hat{\theta}} \gamma_{Tqi} - \frac{1}{4\epsilon_{qi}}h_{qi}^2 z_{qi},
$$

(20)
where $k_i > 0; \varepsilon_i > 0$. Similar with $h_2$ in step 2, $h_i = h_i(x_{qi}, \hat{\theta}_\pi, t)$ is a sufficiently smooth function such that

$$h_i \geq |\phi_{qi}^T \hat{\theta}_\pi| + |\dot{D}_i| + |k_i \Delta x_i| + |\Delta x_{i-1}| + |\phi_i^T \theta|.$$  \hfill (21)

**Lemma 4.** $\alpha_i$, $\frac{\partial \alpha_i}{\partial \gamma}$, $\frac{\partial \alpha_i}{\partial \theta}$ and $\frac{\partial \alpha_i}{\partial \hat{\theta}}$ satisfy the Lipschitz condition with respect to $x_j$.

Consider the Lyapunov candidate function $V_i = V_{i-1} + \frac{1}{2}z_i^2$. From (19)-(21), the derivative of $V_i$ is

$$V_i \leq z_i z_{i+1} + \sum_{j=1}^{n-1} \frac{\partial x_{ji}}{\partial \theta} z_{j+1}(\gamma \tau_{qi} - \hat{\theta}) - \sum_{i=1}^{n-1} k_i z_i^2 + \sum_{j=1}^{n-1} z_i(\beta_j - \alpha_j + \frac{1}{4} k_i^2 h_j^2 \Delta x_j)$$

$$+ \sum_{i=1}^{n-1} \epsilon_i + \sum_{i=3}^{n-2} \frac{\partial x_{ji}}{\partial \theta} \gamma \phi_{qi}^T (z_{j+1} \Delta x_i - z_i \Delta x_{i+1}).$$  \hfill (22)

**Step n:** Consider the $n$th equation of (1). The derivative of $z_n$ is given by

$$\dot{z}_n = \phi_{ni}^T \theta + u + D_n - \frac{\partial \alpha_{n-1}}{\partial \theta} - \frac{\partial \alpha_{n-1}}{\partial \hat{\theta}} - \sum_{j=1}^{n-1} \frac{\partial \alpha_{n-1}}{\partial x_{qi}} x_{qi+1}$$

$$+ \frac{\partial \alpha_{n-1}}{\partial \theta} \gamma \tau_{qn} + \left( \sum_{j=1}^{n-1} \frac{\partial \alpha_{n-1}}{\partial x_{qi}} x_{qi+1} \right) \gamma \phi_{qn} - \frac{1}{4} h_n^2 z_{qn},$$  \hfill (24)

where $k_n > 0$ and $\varepsilon_n > 0$. $h_n$ satisfies

$$h_n \geq |\phi_{qi}^T \hat{\theta}_\pi| + |\dot{D}_n| + |k_n \Delta x_n| + |\Delta x_{n-1}| + |\phi_i^T \theta|.$$  \hfill (25)

Consider the Lyapunov candidate function $V_n = V_{n-1} + \frac{1}{2}z_n^2$. From (20), the derivative of $V_n$ is

$$V_n \leq \sum_{j=1}^{n-1} \frac{\partial x_{ji}}{\partial \theta} z_{j+1}(\gamma \tau_{qn} - \hat{\theta}) - \sum_{i=1}^{n-1} k_i z_i^2 + \sum_{j=1}^{n-1} z_i(\beta_j - \alpha_j + \frac{1}{4} k_i^2 h_j^2 \Delta x_j)$$

$$+ \sum_{i=1}^{n-1} \epsilon_i + \sum_{i=3}^{n-2} \frac{\partial x_{ji}}{\partial \theta} \gamma \phi_{qi}^T (z_{j+1} \Delta x_i - z_i \Delta x_{i+1}).$$  \hfill (26)

The above analysis is synthesized into the following theorem:

**Theorem 1.** Consider the system (1) with quantized state feedback under the control law (24) and the adaptive law

$$\dot{\hat{\theta}} = \gamma \tau_{qn}.$$  \hfill (27)

There exists a constant $\mathcal{L}_f > 0$ such that if $k_i > \frac{1}{2} + \mathcal{L}_f \delta_{\max}$, the closed-loop system satisfies

$$V_n(z(t)) \leq e^{-2k_i t} V_n(z(0)) + \frac{C_i}{k_c} (1 - e^{-2k_i t})$$  \hfill (28)
where \( k_c = \min_i \{ k_i - \frac{1}{2} - \mathcal{L}_f \delta_{\text{max}} \} > 0; \)

\[
C_1 = \sum_{j=1}^{n} \varepsilon_j + \frac{1}{2} \mathcal{L}_f^2 (\delta_{\text{max}} |r| + \omega_{\text{max}})^2. \tag{29}
\]

Furthermore, if the quantization errors are sufficiently small and the external disturbance fades away after a while, the closed-loop system is asymptotically stable.

**Proof.** From (26) and the adaptive law (27), we have

\[
\dot{V}_n \leq -\sum_{j=1}^{n} k_j z_j^2 + \sum_{j=1}^{n} \varepsilon_j + \sum_{j=1}^{n} z_j (\beta_j - \alpha_j + \frac{1}{4} h_j^2 \Delta x_n) + \sum_{j=1}^{n} \frac{1-2}{\delta_j} \frac{\partial \hat{\alpha}_j}{\partial \theta} \gamma_{\psi j} (z_{j+1} \Delta x_n - z_{n} \Delta x_{n+1}). \tag{30}
\]

For all \( 0 \leq i < n, \) it should be noted that \( \beta_i \neq \alpha_i, \) due to the state quantization. From Lemmas 2–4, there exists a constant \( \mathcal{L}_f > 0, \) such that

\[
|\beta_i - \alpha_i (\tilde{x}_i, \tilde{\theta}, t)| \leq |\beta_i - \alpha_i (x_i, \tilde{\theta}, t)| + |\alpha_i (x_i, \tilde{\theta}, t) - \alpha_i (\tilde{x}_i, \tilde{\theta}, t)| \leq \mathcal{L}_f \| \Delta x_n \| \tag{31}
\]

Denoting \( \mathcal{L}_n = 0 \) and taking (31) into (30), it becomes

\[
\dot{V}_n \leq -\sum_{j=1}^{n} k_j z_j^2 + \sum_{j=1}^{n} \varepsilon_j + \sum_{j=1}^{n} z_j (\mathcal{L}_f + \frac{1}{4} h_j^2) \| \Delta x_n \| + \sum_{j=1}^{n} \frac{1-2}{\delta_j} \frac{\partial \hat{\alpha}_j}{\partial \theta} \gamma_{\psi j} (z_{j+1} \Delta x_n - z_{n} \Delta x_{n+1}) \| \| \Delta x_n \|
\]

\[
= -\sum_{j=1}^{n} k_j z_j^2 + \sum_{j=1}^{n} \varepsilon_j + f \| \Delta x_n \|. \tag{32}
\]

where

\[
f = \sum_{j=1}^{n} \frac{1-2}{\delta_j} \frac{\partial \hat{\alpha}_j}{\partial \theta} \gamma_{\psi j} (z_{j+1} \Delta x_n - z_{n} \Delta x_{n+1}) + \sum_{j=1}^{n} z_j (\mathcal{L}_f + \frac{1}{4} h_j^2) \| \Delta x_n \|. \]

It is obvious that \( f \) satisfies Lipschitz condition with respect to \( z_n. \) Subsequently, noting that \( f(0) = f|_{z_n=0} = 0, \) there exists a constant \( \mathcal{L}_f > 0, \) such that

\[
|f(z_n)| = |f(z_n) - f(0)| \leq \mathcal{L}_f \| z_n \|. \tag{33}
\]

Invoking (33), (32) becomes

\[
\dot{V}_n \leq -\sum_{j=1}^{n} k_j z_j^2 + \sum_{j=1}^{n} \varepsilon_j + \mathcal{L}_f \| z_n \| \| \Delta x_n \| \leq -\sum_{j=1}^{n} (k_j - \frac{1}{2} - \mathcal{L}_f \delta_{\text{max}}) z_j^2 + C_1, \tag{34}
\]

This leads to (28).

The remainder of the theorem can be proved directly based on the results in [8]. \( \square \)

**Remark 2.** As mentioned above, the ARC method in [8] aims at the strict-feedback system with full state feedback, and it is not suitable for quantized state feedback. The proposed approach is based on the adaptive robust control method and can be regarded as an extension of the ARC method. Ignoring the state quantization, the designed controller (24) degrades into the ARC law proposed in [8], in which the bounds that the states of the system converge to and the convergence rate are
determined by the control parameters $k_i$ and $\varepsilon_i$; the converge rates of the parameter estimators are determined by the adaptive parameter matrix $\gamma$. Moreover, $\beta_i = \alpha_i$, i.e., the Lyapunov function $V_n(t)$ becomes the traditional form in [5,8].

**Remark 3.** (28) implies that the closed-loop system is UUB. Moreover, with the increase of $t$, the tracking error is exponentially converged into a small range around the origin point with the radius no more than $\sqrt{C_2}$. From (29), the tracking performance can be improved by decreasing the pre-given constants $\varepsilon_i$ or the signal quantization errors.

### 3.2. Backstepping-Based Arc with Quantized States and Input

In this section, we concern the closed-loop system with quantized signal transmission. The results are synthesized into the following theorem:

**Theorem 2.** Choose $k_i > 1 + L_f \delta_{\text{max}} + \delta_u L_u$. The plant (1) under the quantified form of adaptive robust controller

$$u_q = Q_u(u)$$

and the adaptive law (27). If Assumptions 1–4 hold, the closed-loop system is UUB. In addition, the tracking performance can be improved by decreasing the pre-given constants $\varepsilon_i$ or the signal quantization errors.

**Proof.** According to (24) and the Lemmas 1–4, $u$ satisfies the Lipschitz condition with respect to $z_n$. Thus, there exists a constant $L_u > 0$, such that

$$|u| = |u(z_n) - u(0)| \leq L_u z_n.$$

(36)

Consider the derivative of $V_n$ along the new trajectory as below.

$$V_n = V_n - z_n \dot{\theta}^\top \theta + z_n \dot{u} - z_n \frac{\partial u}{\partial t} - z_n \frac{\partial u}{\partial x_q} x_q + z_n (u_q - u).$$

(37)

Invoking (3), (34) and (36), (37) becomes

$$V_n \leq -k_c \sum_{j=1}^n z_j^2 + C_1 + |z_n| |\delta_u| |u| + (1 - \delta_u) \omega_u$$

$$\leq -k_c \sum_{j=1}^n z_j^2 + C_1 + \delta_u \delta_u \omega_u ||z_n||^2 + (1 - \delta_u) \omega_u ||z_n||$$

(38)

$$\leq - (k_c - \delta_u \delta_u - \frac{1}{2}) \sum_{j=1}^n z_j^2 + C_2.$$ 

where $C_2 = C_1 + \frac{1}{2} (1 - \delta_u) \omega_u ^2$. The first item of (38) is negative definite, and the second item is bounded. Thus, the closed-loop is UUB. In addition, the tracking performance can be improved by decreasing $C_2$, which is related to the pre-given constants $\varepsilon_i$ or the signal quantization errors. This completes the proof. □

### 4. Results Validation

In order to verify the theoretical conclusion in Section 3, a contrast experiment is carried out in this section for a three-order nonlinear strict-feedback system under both uncertain parameters and disturbance, which can describe the dynamic of a practical linear-motor-driven gantry system.
\[
\begin{aligned}
\dot{x}_1 &= x_2 + D_1(x_1, t) \\
\dot{x}_2 &= x_3 + \varphi_1^\top (\bar{x}) \theta + D_2(x_1, x_2, t) \\
\dot{x}_3 &= u + \varphi_2^\top (\bar{x}) \theta + D_3(x_1, x_2, x_3, t)
\end{aligned}
\]  

(39)

where the states \(x_1, x_2\) and \(x_3\) are the position, velocity and electric current of the system; the input signal \(u\) is the voltage applied to the motor; \(\theta = [B, A_f, E, R]^\top\) stands for the vector of unknown parameters; \(B, A_f, E\) and \(R\) represent the viscous coefficient, Coulomb coefficient, inductance factor and resistance, respectively; \(\varphi_1 = [-x_2, -\arctan(x_2), 0, 0]^\top\) and \(\varphi_2 = [0, 0, -x_2, -x_3]^\top\) are known function vectors. To verify the effectiveness of the proposed control approach under strong disturbance, the unknown functions are set as \(D_1 = d_1 \sin(x_1 t), D_2 = d_2 (1 - \cos(x_1 x_2 t))\) and \(D_3 = d_3 \tanh(x_3)\).

For this simulation, the time interval is \(T = 0.001\). The parameter settings of the system uncertainties, initial state values, quantizers and control schemes are shown in Tables 1–4.

**Table 1.** The settings of the system uncertainties.

|       | \(B\) | \(A_f\) | \(E\) | \(R\) | \(d_1\) | \(d_2\) | \(d_3\) |
|-------|-------|-------|-------|-------|--------|--------|--------|
| Value | 0.15  | 0.05  | 0.8   | 10    | 0.05   | 0.02   | 0.05   |
| Bound | [0.05,0.5] | [0.02,0.5] | [0.2,1] | [1,10] | -       | -       | -       |

**Table 2.** The settings of the initial values.

|       | \(\hat{B}(0)\) | \(\hat{A}_f(0)\) | \(\hat{E}(0)\) | \(\hat{R}(0)\) | \(x_1(0)\) | \(x_2(0)\) | \(x_3(0)\) |
|-------|---------------|-----------------|---------------|---------------|----------|----------|----------|
| Value | 0.1           | 0.1             | 1             | 5             | 0        | 0        | 0        |

**Table 3.** The parameter settings of the quantizers.

|               | State quantizer | Input quantizer | State quantizer | Input quantizer |
|---------------|-----------------|-----------------|-----------------|-----------------|
| Uniform quantizer | \(\alpha_{x_1} = \alpha_{x_2} = \alpha_{x_3} = 0.05\) | \(\alpha_u = 1\) | \(\delta_{x_1} = \delta_{x_2} = \delta_{x_3} = 0.05\) | \(\delta_u = 0.1\) |
| Logarithmic quantizer | \(\alpha_{x_1} = \alpha_{x_2} = \alpha_{x_3} = 0.01\) | \(\alpha_u = 1\) |          |          |

**Table 4.** The parameter settings of the control scheme.

| Parameter | Value | Parameter | Value |
|-----------|-------|-----------|-------|
| \(k_1\)  | 3     | \(\varepsilon_1\) | 0.2   |
| \(k_2\)  | 1     | \(\varepsilon_2\) | 0.2   |
| \(k_3\)  | 5     | \(\varepsilon_3\) | 0.2   |
| \(\gamma_1\) | 0.02 | \(\varepsilon_{\theta_1}\) | 0.01 |
| \(\gamma_2\) | 0.02 | \(\varepsilon_{\theta_2}\) | 0.01 |
| \(\gamma_3\) | 0.02 | \(\varepsilon_{\theta_3}\) | 0.01 |
| \(\gamma_4\) | 5 | \(\varepsilon_{\theta_4}\) | 0.1   |
In order to test both the stabilization and tracking performance under the designed controller with the uniform and logarithmic quantizer, respectively, the testings in Table 5 are carried out in this section.

Table 5. Settings of the testings.

| Testings | Quantizer          | Trajectory        |
|----------|--------------------|-------------------|
| T1       | Uniform quantizer  | \( r(t) \equiv 1 \) |
| T2       | Logarithmic quantizer | \( r(t) \equiv 1 \) |
| T3       | Uniform quantizer  | \( r(t) = \sin(t) \) |
| T4       | Logarithmic quantizer | \( r(t) = \sin(t) \) |

The results of Testings T1–T2 are shown in Figures 4–6, which illustrate the tracking performance of Testings T1–T2 and their inputs, respectively. From Figures 4 and 5, the closed-loop system works well and is stable under the designed control approach in spite of strong uncertainties. Moreover, the system responds quickly to the desired steady-state value and converges into a small neighborhood around it whether using uniform quantizers or logarithmic quantizers, which validates the effectiveness of the proposed method on a stabilization mission.

Figures 7–10 display the results of Testings T3–T4. Based on Figures 7–9, the responses of the system to a sinusoidal signal are all stable regardless of employing uniform quantizers or logarithmic quantizers. In addition, although strong disturbances are applied to the system, the stability of the system is not very affected, and the adaptive laws help the closed-loop system achieve a better performance over time. These results verify the effectiveness of the proposed method on a tracking task.

5. Conclusions

In this article, a class of networked nonlinear systems in strict-feedback form is studied and a quantized backstepping adaptive robust control method, which inherits the advantages of ARC and backstepping methods. In order to analyze the effectiveness of the proposed method, we construct a novel Lyapunov candidate function $V(t)$ which is differentiable and positive definite, although the virtual control law is nondifferentiable. By analyzing the novel positive definite function, the closed-loop system under the designed controller is uniformly ultimate bounded, and the tracking error is related to a pre-given constant and quantization errors. A backstepping ARC scheme is designed for the plant with quantized states and input. The conclusions are also verified by the simulation results. However, some shortcomings of ARC and backstepping methods are also retained, such as the explosion of terms caused by the backstepping method and the nontrue parameter estimation of the ARC law, which lights a path for our future research.
