1. Introduction

Intensification of heat and mass transfer processes under the action of external vibration forces is achieved mainly as a result of increasing the contact surface area of the phases and, respectively, of the heat and mass transfer coefficients. The latter, according to most researchers, is due to additional energy consumption to provide the required speed of the drying agent.

In [2], the author investigates the process of drying pumpkin seeds in a stationary state, using the energy of the sun. The advantage of this method is the low energy costs, and the disadvantage is uneven heating of the layer during the processing cycle, which leads to considerable process duration.

In [3], the drying process in the moving layer is considered, where the suspended state of the seed material is ensured by blowing the drying agent at speeds of 2.39–2.87 m/s. This method does not guarantee uniform heating of the seed and causes additional energy consumption to provide the required speed of the drying agent.

In [4], the influence of the drying process on the quality properties of pumpkin oil was investigated. The

2. Literature review and problem statement

In [1], the theoretical and experimental study of the vibration influence on these processes with the aim of their intensification and creation of high-intensity drying equipment is an urgent task.

Vibrational convective drying of pumpkin seeds was studied in [2–4]. In the experimental conditions, the seed material was in a stationary state, using the energy of the sun. The advantage of this method is the low energy costs, and the disadvantage is the uneven heating of the layer during the processing cycle, which leads to considerable process duration.

In [3], the drying process in the moving layer is considered, where the suspended state of the seed material is ensured by blowing the drying agent at speeds of 2.39–2.87 m/s. This method does not guarantee uniform heating of the seed and causes additional energy consumption to provide the required speed of the drying agent.

In [4], the influence of the drying process on the quality properties of pumpkin oil was investigated. The
The aim of this work is to determine the kinetics of vibration-convective drying of pumpkin seeds in the humidity range of 38–10%. This will allow finding rational parameters of the process and equipment for drying seed lots of pumpkin seeds in order to preserve their conditioning properties.

To achieve this aim, the following objectives were defined:
- to substantiate the rational parameters of the process, in particular, the maximum permissible values of the temperature of the drying agent and heating of the pumpkin seed layer, as well as the feasibility of vibration activation, as a significant intensifying factor;
- to derive dependencies for calculating the duration and speed of drying of pumpkin seeds in the first period in the studied range of the process parameters.

3. The aim and objectives of the study

The methods of theoretical and analytical mechanics, continuum mechanics, in particular visco-plasticity mechanics, mechanics of bulk discrete media, were used. Experimental studies used the methods of planning a factor experiment, methods of electrical measurements of non-electrical quantities.

Microsoft Excel, Grapher software packages were used to visualize the research results.

Determination of quality indicators of seeds was carried out in testing laboratories in accordance with NSU 4138-2002 and NSU 7160: 2010.

4. Materials and methods for determining the kinetics of the process of pumpkin seeds vibration-convective drying

The methods of theoretical and analytical mechanics, continuum mechanics, in particular visco-plasticity mechanics, mechanics of bulk discrete media, were used. Experimental studies used the methods of planning a factor experiment, methods of electrical measurements of non-electrical quantities.

The methods of theoretical and analytical mechanics, continuum mechanics, in particular visco-plasticity mechanics, mechanics of bulk discrete media, were used. Experimental studies used the methods of planning a factor experiment, methods of electrical measurements of non-electrical quantities.

5. Results of determining the kinetics of the process of pumpkin seeds vibration-convective drying

During the experimental study of the process of drying pumpkin seeds, it was found that the drying occurs in two stages. The first is vibrational and filtration drying of the material from the humidity of 52% to 38%; the second is vibrational and convective drying from the humidity of 38% to 10%. The hydrodynamics and kinetics of the first stage of drying were considered in [10, 11]. Experimental studies of the second stage of drying were carried out using the pilot-industrial sample of filtration-convective vibrating dryer [12, 13], its schematic diagram is shown in Fig. 1.

The filtration-convective vibrating dryer consists of a drying chamber mounted on elastic supports 2. The working chamber, which is oscillated by means of a vibrator 3, has a neck 4 above to remove the spent drying agent, and a perforated U-shaped bottom below. The supply system of the heated drying agent consists of a fan 6 and electric heating elements 7. Position 8 indicates the direction of movement of the drying agent, and position 9 – pumpkin seeds to be dried.

The filtration-convective vibrating dryer works as follows. The vibrator 3 drives the drying chamber 1 with pumpkin seeds 9 mounted on the elastic supports 2. The dry-
ing agent supplied by the fan 6 passes through the electric heating elements 7, is heated to a predetermined temperature and, through the perforated U-shaped bottom 5 of the working chamber 1, passes through the pumpkin seeds 9 in the direction 8 and is removed through the neck 4.

Measurement of the coolant and seed layer temperature was carried out using thermocouples of ChC type and semiconductor integral thermometers of DS18B20 type. For research, pumpkin seeds of different ripeness, years of harvesting, degree of surface cleaning were used.

Fig. 1. Schematic diagram of the filtration-convective vibrating dryer: 1 – drying chamber; 2 – elastic supports; 3 – vibrator; 4 – neck; 5 – perforated U-shaped bottom; 6 – fan; 7 – electric heating elements; 8 – direction of movement of the drying agent; 9 – pumpkin seeds

The initial values of pumpkin seed temperature (humidity \( W = 38 \% \)) were taken considering the results of the previous stage studies – filtration drying [11].

The process of vibrational and convective drying of pumpkin seeds, based on the angle of inclination of the obtained dependence curves (Fig. 2, 3), can be divided into two periods. In the first period of drying pumpkin seeds (in the humidity range of 38–17 %), intensive removal of moisture with a constant speed of drying due to evaporation from the surface of the dried material is observed. Therefore, in this humidity range, the kinetic curves are depicted by straight lines whose slope depends on the speed of the drying process. The second period (within the humidity range of 17–10 %) is characterized by a lower drying rate, which is shown on the kinetic curves (Fig. 2, 3) by curvilinear sections, the slope of which indicates the slowdown of the process.

The study of the kinetics of vibration-convective drying of pumpkin seeds was carried out under the following parameters: the filling factor of the drying chamber, the speed and temperature of the drying agent, the vibration amplitude of the drying chamber.

Investigation of the effect of the filling factor of the drying chamber (1 – 0.25; 2 – 0.5; 3 – 0.75; 4 – 1) on drying kinetics was carried out at the drying agent temperature \( t_{da} = 50 \degree C \), velocity \( V_{da} = 0.6 \text{ m/s} \) and vibration acceleration \( Ao^2 = 138 \text{ m/s}^2 \). As a result, it was found that if the drying chamber is 100 % full, the total drying time increases by 1/3 (from 4,000 s to 6,000 s) compared to the drying time by filling the drying chamber by 0.25. In the case of 100 % complete filling of the drying chamber, the second drying period starts in 3,000 s and lasts 3,000 s, and when filled by 25 % – in 2,100 s and lasts 1,900 s. Therefore, there is a direct dependence – the increase in the duration of the first and second drying periods and the drying process as a whole on the filling factor of the drying chamber (Fig. 2).

Kinetic curves (Fig. 2–12) are constructed directly from the results of experimental studies of the process of vibration-convective drying of pumpkin seeds in a filtration-convective vibrating dryer (Fig. 1) with the following variables: the filling factor of the drying chamber, the speed and temperature of the drying agent, vibration amplitude of the drying chamber. The curves are constructed to study the regularity of the process itself depending on the variables. Kinetic curves are the initial stage for mathematical processing of the results of studying the kinetics of the drying process.

Fig. 2. Changes in the humidity of pumpkin seeds from the duration of vibration-convective drying at different filling factors of the drying chamber at \( t_{da} = 50 \degree C \); \( V_{da} = 0.6 \text{ m/s} \); \( Ao^2 = 138 \text{ m/s}^2 \): 1 – \( K_f = 0.25 \); 2 – \( K_f = 0.5 \); 3 – \( K_f = 0.75 \); 4 – \( K_f = 1.0 \).

Fig. 4, 5 contain the results of the study of the influence of the coolant velocity (1 – 1 m/s; 2 – 0.8 m/s; 3 – 0.6 m/s; 4 – 0.4 m/s) on the kinetics of vibration-convective drying for the filling factor of the drying chamber \( K_f = 0.75 \), vibration acceleration \( Ao^2 = 138 \text{ m/s}^2 \) and coolant temperature \( t_{da} = 50 \degree C \).

At the coolant velocity \( V_{da} = 0.4 \text{ m/s} \), the first and the second drying periods last for 3,000 s (total drying time is 6,000 s), and for \( V_{da} = 1 \text{ m/s} \) – the second drying period begins in 2,000 seconds and lasts 1,600 s (total drying time
is 3,600 s). So, the coolant velocity also has a significant impact on the duration of the first and the second drying periods and the drying process of pumpkin seeds in general.

The results of the studies on the effect of vibration frequency (Fig. 8, 9) indicate a direct relationship between the vibration frequency of the drying chamber and drying time: the higher the frequency, the greater the intensity of vibration-convective drying. As can be seen from Fig. 8, for the vibration frequency $f=10$ Hz, the second period begins in 3,200 s and lasts 2,800 s, and the total drying time is 6,000 s. For the vibration frequency $f=25$ Hz, the second drying period begins in 2,000 seconds and lasts for 2,200 seconds, and the total drying time is 4,200 seconds, which is almost 1.5 times less than for $f=10$ Hz.

The results of studying the influence of the coolant temperature in the range of 40–60 °C on the kinetics of vibration-convective drying of pumpkin seeds at a coolant velocity of 0.6 m/s, vibration acceleration $A_0^2=138$ m/s$^2$ and filling factor of the drying chamber of 0.75 are shown in Fig. 10, 11. The obtained results indicate an increase in the process intensity, both in the first and second periods of drying with increasing temperature of the thermal agent. As can be seen from Fig. 10, at a temperature of 40 °C, the second drying pe-
period begins in 3,600 s and lasts for almost 3,000 s, the total drying time is 6,500 s. At the coolant temperature of 60 °C, the second period of drying occurs already in 1,800 s and lasts for 1,800 s, and the total drying time is 3,600 s, which is 1.8 times less than at 40 °C. Consequently, the higher the coolant temperature, the more intense the drying process is.

However, the drying temperature of a product such as pumpkin seeds is limited to a certain level in order not only to reduce their humidity, but also to simultaneously preserve their germination ability and energy [14, 15]. In the reference literature [16, 17], it is determined that the maximum permissible heating temperature of pumpkin seeds is $t_{h, max, permissible}$=47°C for the corresponding duration of the heating (drying) process. Detailed definitions of rational parameters of the drying process, taking into account the permissible values of the heating temperature of pumpkin seeds are highlighted in [18].

The average heating temperature of the seed surface was determined by the method of measuring «in a suddenly lowered layer» [19, 20], when the supply of coolant and vibration were temporarily stopped. The error of this measurement method does not exceed 0.5 %.

As a result of the research, it was found that during the drying of pumpkin seeds at a temperature of the thermal agent of 50°C, the average heating temperature of the surface of the dried material is practically the same throughout the layer and does not exceed $t_{d2}=46.7$ °C, that is, is within the permissible values.

Measurements of the nucleus (embryo) temperature of pumpkin seeds were not carried out, since they are suitable for conducting thorough research of the selection direction, in particular, the influence of temperature on the structural biochemical properties of seeds.

During the studies of the kinetics of vibration-convective drying, the dynamics of the surface heating temperature of pumpkin seeds was also determined (Fig. 12).

To determine the values of the critical humidity of the seeds $W_{cr}$ at different temperatures and speeds of the drying agent, the filling factor of the drying chamber, as well as the drying time in the first period $\tau_{cr}$, the method was used to construct kinetic curves in the $\lg(W-W_0)/f(\tau)$ coordinates. On the basis of the results of experimental research, the critical humidity and the time of its achievement for different parameters of the drying agent and operating modes of the drying equipment were determined by the graph-analytical method. In order to find the dependence of the duration of vibration-convective drying of pumpkin seeds in the first period on the drying rate, we shall present the graphic dependence $N_{exp}=f(\tau_{cr})$, shown in Fig. 13.

The dependence of the critical drying time $\tau_{cr}$ on the drying rate $N_{exp}$ in the first period is described by the equation:

$$\tau_{cr} = 7.68 \frac{N}{N_{exp}}. \quad (1)$$

The obtained dependence (1) is valid in the investigated range of the speeds of vibration-convective drying (Fig. 13), namely $0.0056 \% / \text{s}<N<0.0125167 \% / \text{s}$. The confidence factor of approximation $R^2$ is 0.942637, which is quite acceptable and characterizes the smoothing as reliable. The obtained dependence coefficients are found to be statistically significant.

The drying rate in the first period $N$ will depend on the operating parameters of the drying equipment and can be represented in general by the equation [8]:

$$N = A \cdot t_{cr}^{-2} \cdot K_f^{0.75} \cdot V_{da}^{0.33}. \quad (2)$$

Fig. 13. Dependence of the speed of vibration-convective drying $N$ of pumpkin seeds on the critical drying time $\tau_{cr}$.

According to the calculations, the unknown coefficients of the drying process are found, then the drying rate in the first period of vibration-convective drying of pumpkin seeds can be determined by the equation:

$$N_p = 1.016 \cdot 10^{-3} \cdot t_{cr}^{2.74} \cdot K_f^{-0.33} \cdot V_{da}^{0.36}. \quad (3)$$

The calculated empirical dependence (3) is valid in the studied range of:
- coolant temperature $40 \ ^\circ \text{C}<t_{da}<60 \ ^\circ \text{C}$;
- coolant velocity $0.4 \text{ m/s}<V_{da}<1 \text{ m/s}$;
- drying chamber filling factor $0.25<K_f<1$.

The confidence factor of linear approximation $R^2$ is 0.954705, which is quite acceptable. The obtained dependence coefficients are found to be statistically significant.

From the analysis of equation (3), it can be seen that with the growth of coolant temperature and velocity, the drying rate in the first period increases, and with the increase of the filling factor of the drying drum (the height of the pumpkin seed layer), respectively, decreases. This is confirmed by numerical experimental studies [8]. Comparison of the calculated and experimental values of the drying rate of pumpkin seeds in the first period is satisfactory, and the relative error does not exceed 8 %, which is a permissible value.

6. Discussion of results of determining the kinetics of the process of pumpkin seeds vibration-convective drying

The graphs (Fig. 2–12) obtained by conducting experimental studies to determine the dependencies of the study of the kinetics of the process of vibrational and convective drying of pumpkin seeds make it possible to summarize them for determining rational parameters:
- $K_f=0.75$, typical for most vibration machines;
- $A=18 \text{ mm}$, corresponds to the largest pumpkin seed size;
- $V_{da}=0.6 \text{ m/s}$, sufficient for the drying agent to access the surface of each seed without affecting its trajectory;
- $t_{da}=50 \ ^\circ \text{C}$, provides a thermal effect on pumpkin seeds without exceeding the maximum allowable heating temperature.
Small values of these parameters would not intensify the drying process and larger ones would require additional energy. The above rational parameters make it possible to obtain the dependencies (1)–(3) for calculating the duration and speed of drying pumpkin seeds.

The conducted researches prove the feasibility of using mechanical vibrations in the process of drying high-moisture pumpkin seeds, as this will provide intensive and energy-saving modes of processing with a simultaneous sparing effect on the seed material.

The advantages are determination, substantiation and coordination of rational technological and operating parameters of the process and equipment of vibrational and convective of pumpkin seeds.

The disadvantages are that the work was limited to studies of one crop, which requires verification of the results obtained when used for other crops.

The results obtained are practically significant for drying sowing lots of pumpkin seeds in agricultural enterprises, as they guarantee high quality of the seed material, which has been tested in a certified laboratory according to [14]: germination ability – at least 95%; germination energy – not less than 90%.

The presented studies are the final stage of the complex studies of one crop, which requires verification of the results obtained when used for other crops.

Thus, the performed work gives grounds to claim that the scientific hypothesis of drying high-moisture pumpkin seeds in two stages using vibratory equipment by providing the required mode of vibration movement of the processed material in the working chamber with gentle processing modes is correctly formulated and theoretically and experimentally justified.

7. Conclusions

1. Rational parameters of the process of vibrational-convective drying of pumpkin seeds are determined, in particular, the maximum permissible temperature of the drying agent is \( t_{da} = 50 \) °C, which corresponds to the maximum permissible heating temperature of seeds \( t_{da} = 46.7 \) °C, at which the grain retains the conditioning values of germination ability and germination, coolant velocity is 0.6 m/s, vibration acceleration \( A_o = 138 \) m/s², filling factor of the drying chamber \( K_f = 0.75 \), vibration amplitude of the drying chamber \( A = 18 \) mm, and drying time is 105 min.

2. The dependence was determined for calculating the duration and speed of pumpkin seeds drying, taking into account the operating parameters of the vibratory dryer in a certain range: coolant temperature is \( 40 \) °C<\( t_{da} < 60 \) °C; coolant velocity is \( 0.40 \) m/s<\( V_{da} < 1 \) m/s; drying chamber filling factor is \( 0.25 < K_f < 1 \).

1. Introduction

Increasing the productivity of livestock bio-objects is an important and quite complex economic problem. Its complete or partial solution requires systematic fundamental research and applied developments aimed at the construction of the theoretical foundations of automated environmentally safe and resource-saving electro-technical complexes. These complexes ensure the thermal mode of the microclimate of production premises and structures and determine optimal
