Abstract. The ≃ 100 kg highly radiopure NaI(Tl) set-up of the DAMA project (DAMA/NaI) took data over seven annual cycles up to July 2002 and has achieved results on various rare processes. Its main aim has actually been the exploitation of the model independent WIMP annual modulation signature. After this conference the total exposure, collected during the seven annual cycles, was released. This cumulative exposure (107731 kg × day) has given a model independent evidence for the presence of a Dark Matter particle component in the galactic halo at 6.3 σ C.L.; this main result is summarised here. Some of the many possible corollary model dependent quests for the candidate particle are mentioned. At present, after about five years of new developments, a second generation low background set-up (DAMA/LIBRA with a mass of ≃ 250 kg NaI(Tl)) was built and is taking data since March 2003. New R&D efforts toward a possible NaI(Tl) ton set-up, we proposed in 1996, have been funded and started in 2003.

1 Introduction

The DAMA project has been proposed by the italian group to INFN and firstly funded in 1990 [1]; in 1992 the chinese colleagues joined the project. DAMA is an observatory for rare processes based on the development and use of various kinds of radiopure scintillators. Several low background set-ups have been realised; the main ones are: i) DAMA/NaI (≃ 100 kg of radiopure NaI(Tl)), which took data underground over seven annual cycles and was put out of operation in July 2002; ii) DAMA/LXe (≃ 6.5 kg liquid Xenon), which has been upgraded various times and is in operation; iii) DAMA/R&D, which is a set-up devoted to measurements on prototypes/small–scale–experiments and is in operation; iv) the new second generation set-up DAMA/LIBRA (≃ 250 kg; more radiopure NaI(Tl)) in operation since March 2003. Moreover, in the framework of devoted R&D for higher radiopure detectors and PMTs, sample measurements are regularly

** also: University of Zhao Qing, Guang Dong, China
carried out by means of the low background DAMA/Ge detector, installed deep underground since \( \gtrsim 10 \) years and, in some cases, by means of Ispra facilities. Recent results from DAMA/LXe are presented in these proceedings elsewhere [2], while in ref. [3] some recent results achieved with DAMA/R&D can be found.

The DAMA/NaI set-up and its performances have been described in details in ref. [4]. Since then some upgrading has been carried out; in particular, in summer 2000 the electronic chain and data acquisition system were completely substituted as reported in ref. [5].

As mentioned, DAMA/NaI has taken data over seven annual cycles up to July 2002 [5]. The first data release and publication of DAMA/NaI data occurred in 1996 [6] for an exposure of 4123 kg \( \times \) day (DAMA/NaI-0) analysed by using the pulse shape discrimination (PSD) technique in NaI(Tl) in order to discriminate between electromagnetic background and recoils\(^1\). Investigation of possible diurnal effects has been carried out as well [8]. The main aim of the experiment was actually the investigation of the presence of a Dark Matter particle component in the galactic halo by means of the model independent WIMP annual modulation signature, which has been deeply investigated over seven annual cycles (107731 kg \( \times \) day total exposure).

DAMA/NaI has also obtained results on the investigation of some exotic Dark Matter candidates (such as neutral SIMPs, neutral nucleareties and Q-balls) [9], has searched for solar axions [10] and has given results on several other rare processes such as e.g. spontaneous emission of protons in \(^{23}\)Na and \(^{127}\)I with violation of the Pauli exclusion principle [11], nuclear level excitation of \(^{23}\)Na and \(^{127}\)I during charge-non-conserving processes [12], electron stability and non-paulian transitions in Iodine atoms by L-shell[13].

In the following, the result obtained by DAMA/NaI in the investigation of the WIMP annual modulation signature over the seven annual cycles will be briefly summarised. This cumulative 107731 kg \( \times \) day exposure has given a model independent evidence for the presence of a Dark Matter particle component in the galactic halo at 6.3 \( \sigma \) C.L.; this main result and corollary interpretations in some of the possible different model scenarios have been discussed in experimental and theoretical details in ref. [5] and have firstly been presented after this Conference in a seminar at Gran Sasso National Laboratory (LNGS) at end of July 2003.

The new second generation larger mass and higher radiopure NaI(Tl) set-up, named DAMA/LIBRA, is now in operation and will be briefly introduced.

\(^1\) The NaI(Tl) Dark Matter experiments have discrimination capability as largely stated in literature by several groups and at present exploited as main goal by the NAIAD experiment. In Zeplin I the pulse shape discrimination technique has been employed in LXe as well (sometimes this rejection procedure has been indicated as rejection by timing), similarly as done and published by DAMA/LXe in 1998. Moreover, we remind that the WIMP annual modulation signature acts (as pointed out since the 80’s by [7]) itself as a powerful background rejection procedure and that it can be effectively exploited only in large mass experiments such as so far DAMA/NaI and DAMA/LIBRA.
2 Some generalities

The DAMA/NaI experiment has been built in order to have suitable mass, sensitivity and control of the running conditions to investigate the WIMP presence in the galactic halo by the annual modulation signature. We remind that the WIMP annual modulation signature is based on the annual modulation of the signal rate induced by the Earth revolution around the Sun; as a consequence, the Earth will be crossed by a larger WIMP flux roughly in June (when its rotational velocity is summed to the one of the solar system with respect to the Galaxy) and by a smaller one roughly in December (when the two velocities are subtracted). The annual modulation signature is very distinctive since a WIMP-induced seasonal effect must simultaneously satisfy all the following requirements: the rate must contain a component modulated according to a cosine function (1) with one year period, $T$, (2) and a phase, $t_0$, that peaks around $\approx 2^{nd}$ June (3); this modulation must only be found in a well-defined low energy range, where WIMP induced recoils can be present (4); it must apply to those events in which just one detector of many actually "fires" (single-hit events), since the WIMP multi-scattering probability is negligible (5); the modulation amplitude in the region of maximal sensitivity is expected to be $\lesssim 7\%$ (6). For the sake of completeness, we mention that this latter rough limit would be larger either in case the WIMPs would match the scenario of ref. [14] (because of kinematic effects) or the scenario of ref. [15] (because of a possible external contribution to the dark halo from the Sagittarius Dwarf Tidal Stream). To mimic such a signature spurious effects or side reactions should not only be able to account for the whole observed modulation amplitude, but also to contemporaneously satisfy all the requirements; no one has been found or suggested by anyone over about a decade.

As mentioned, to point out the modulation component of a signal, large mass apparata with suitable performances and control of the operating conditions are necessary, such as the $\approx 100$ kg highly radiopure NaI(Tl) DAMA/NaI set-up – which has been the only experiment able to effectively exploit such a WIMP signature for about a decade – and now the $\approx 250$ kg higher radiopure NaI(Tl) DAMA/LIBRA set-up. This approach allows to investigate the presence of a Dark Matter particle component in the galactic halo independently on astrophysical, nuclear and particle physics modelling. Corollary quests for the candidate particle require instead to choose a model; therefore, the results are not general and refer case by case to the considered model framework \(^2\) as it is always the case for results given in form of exclusion plots (which, thus, have no generality) and for the specific parameters of a WIMP candidate (mass and cross sections) derived from the indirect searches (for some discussion see [5]).

\(^2\) We remark that a model framework is identified by the general astrophysical, nuclear and particle physics assumptions and by the set of values used for all the experimental and theoretical parameters needed in the calculations (for example WIMP nature, WIMP couplings, form factors, spin factors, scaling laws, quenching factors, halo model, WIMP local velocity, etc., which are affected by relevant uncertainties; see for example discussions in ref. [5]).
The presence of a model independent positive evidence in the data of DAMA/NaI has been firstly reported by the DAMA collaboration at the TAUP conference in 1997 [16] and published also in [17], confirmed in [18,19], further confirmed in [20–24] and conclusively confirmed, at end of experiment, in 2003 [5]. Corollary model dependent quests for a candidate particle have been carried out in some of the many possible model frameworks and have been improved with time. In particular, some scenarios either for mixed spin-independent (SI) and spin-dependent (SD) coupled WIMPs or for purely SI coupled WIMPs or for purely SD coupled WIMPs have been considered in some of the many possible model frameworks as well as the case of WIMPs with preferred inelastic scattering.

Finally, some comments on the claims for contradiction by Cdmn-I, Edelweiss-I, Zeplin I can be found in ref. [5], where some recent positive hints – not in contradiction with the DAMA/NaI result – from Dark Matter indirect searches are also summarised.

3 Final DAMA/NaI model independent result on WIMP annual modulation signature over 7 annual cycles

A model independent investigation of the WIMP annual modulation signature has been realised by exploiting the time behaviour of the experimental residual rates of the single-hit events in the lowest energy region over seven annual cycles (total exposure: 107731 kg × day) [5], as performed in the past on partial exposures.

The exposure of each annual cycle, DAMA/NaI-1 to -7, is reported in Table 1, where the exposure of the DAMA/NaI-0 running period (partially overlapped with DAMA/NaI-1) is quoted as well.

This model independent approach on the data of the seven annual cycles offers an immediate evidence of the presence of an annual modulation of the rate of the single-hit events in the lowest energy region as shown in Fig. 1 – left, where the time behaviours of the measured (2–4), (2–5) and (2–6) keV single-hit events residual rates are depicted.

---

3 We remind that JHEP 0107 (2001) 044 is not at all in conflict with a purely SD solution since it considered only two particular purely SD couplings (of the many possible) in a strongly model dependent context and using modulation amplitudes valid instead only in a particular purely SI case. Moreover, the mixed SI & SD case was not involved at all in that discussion.

4 Here we just remind e.g. that no model independent comparison is possible among those experiments and DAMA/NaI because of the different methodological approaches, of the different target nuclei, etc. As regards possible model dependent comparisons, those experiments give result in a single purely SI model framework with fixed/selected assumptions, neglecting experimental and theoretical uncertainties and – as also done in this conference – have quoted so far the DAMA/NaI result in an incorrect, unupated and incomplete way and they have been and are ignoring the existence of other solutions.
Table 1. Exposure of each annual cycle (DAMA/NaI-1 to -7) and of the DAMA/NaI-0 running period [6,17–24,5]. See text.

The data favour the presence of a modulated cosine-like behaviour \((A \cdot \cos \omega (t - t_0))\) at 6.3 \(\sigma\) C.L. and their fit for the (2–6) keV larger statistics energy interval offers modulation amplitude equal to \((0.0200 \pm 0.0032)\) cpd/kg/keV, \(t_0 = (140 \pm 22)\) days and \(T = \frac{2\pi}{\omega} = (1.00 \pm 0.01)\) year, all parameters kept free in the fit. The period and phase agree with those expected in the case of a WIMP induced effect \((T = 1\) year and \(t_0\) roughly at \(\approx 152.5^{th}\) day of the year). The \(\chi^2\) test on the (2–6) keV residual rate in Fig. 1 – left disfavours the hypothesis of unmodulated behaviour giving a probability of \(7 \cdot 10^{-4}\) \((\chi^2/d.o.f. = 71/37)\). We note that, for simplicity, in Fig. 1 – left the same time binning already considered in ref. [20,21] has been used; the result of this approach is similar by choosing other time binnings. The experimental residuals given in Fig. 1 – left have also been fitted, according to the previous procedure, fixing the period at 1 year and the phase at 2\textsuperscript{nd} June; the best fitted modulation amplitudes are: \((0.0233 \pm 0.0047)\) cpd/kg/keV for the (2–4) keV energy interval, \((0.0210 \pm 0.0038)\) cpd/kg/keV for the (2–5) keV energy interval, \((0.0192 \pm 0.0031)\) cpd/kg/keV for the (2–6) keV energy interval, respectively.

The same data have also been investigated by a Fourier analysis (performed according to ref. [25] including also the treatment of the experimental errors and of the time binning), obtaining the result shown in Fig. 1 – right, where a clear peak corresponding to a period of 1 year is evident.

In Fig. 2 the experimental single-hit residual rate from the total exposure of 107731 kg × day is presented, as in a single annual cycle, for two different energy intervals; as it can be seen the modulation is clearly present in the (2–6) keV energy region, while it is absent just above.

Finally, a suitable statistical analysis has shown that the modulation amplitudes are statistically well distributed in all the crystals, in all the data taking periods and considered energy bins [5].

**On the investigation of possible systematic effects and side reactions.** As previously mentioned, to mimic the annual modulation signature a system-
Fig. 1. On the left: experimental residual rate for single-hit events in the (2–4), (2–5) and (2–6) keV energy intervals as a function of the time over 7 annual cycles (total exposure 1.07731 kg × day); end of data taking July 2002. The experimental points present the errors as vertical bars and the associated time bin width as horizontal bars. The superimposed curves represent the cosinusoidal functions behaviours expected for a WIMP signal with a period equal to 1 year and phase at 2nd June; the modulation amplitudes have been obtained by best fit [5]. On the right: power spectrum of the measured (2–6) keV single-hit residuals calculated according to ref. [25], including also the treatment of the experimental errors and of the time binning. As it can be seen, the principal mode corresponds to a frequency of $2.737 \cdot 10^{-3} \text{d}^{-1}$, that is to a period of $\simeq 1$ year.

Atactic effect or side reaction should not only be able to account for the whole observed modulation amplitude, but also able to satisfy the requirements of a WIMP induced effect. A careful investigation of all the known possible sources of systematics and side reactions has been regularly carried out and published at time of each data release. In particular, detailed quantitative discussions can be found in ref. [21,5] and will not be repeated here. As it can be seen there,

5 We take this opportunity only to comment that the sizeable discussions reported e.g. in [21,5] already demonstrated that a possible modulation of neutron flux (possibly observed by the ICARUS coll. as reported in the ICARUS internal report TM03-01) cannot quantitatively contribute to the DAMA/NaI observed modulation amplitude, even if the neutron flux would be assumed to be 100 times larger than measured.

Fig. 2. Experimental single-hit residual rate from the total exposure of 107731 kg × day as in a single annual cycle. The experimental points present the errors as vertical bars and the associated time bin width as horizontal bars. The initial time is taken at August 7th. Fitting the data with a cosinusoidal function with period of 1 year and phase at 152.5 days, the following amplitudes are obtained: (0.0195 ± 0.0031) cpd/kg/keV and −(0.0009 ± 0.0019) cpd/kg/keV, respectively. Thus, a clear modulation is present in the lowest energy region, while it is absent just above.

no systematic effect or side reaction able to mimic a WIMP induced effect has been found.

A further result: the multiple-hits events. As a further relevant investigation, the multiple-hits events also collected during the DAMA/NaI-6 and 7 running periods (when each detector was equipped with its own Transient Digitizer with a dedicated renewed electronics) have been studied and analysed by using the same identical hardware and the same identical software procedures as for the case of the single-hit events. The multiple-hits events class – on the contrary of the single-hit one – does not include events induced by WIMPs since the probability that a WIMP scatters off more than one detector is negligible.

Fig. 3 shows the behaviour of the residual rate of multiple-hits events in the (2–6) keV energy interval measured during the DAMA/NaI-6 and -7 running periods as a function of the time in a year. It is compared with the residual rate of the single-hit events measured in the same energy interval with the total exposure. Fitting these data with the function $A \cdot \cos(\omega(t-t_0))$ with period of 1 year and phase at 152.5 days, the following amplitudes are obtained: $A = (0.0195 \pm 0.0031)$ cpd/kg/keV and $A = -(3.9 \pm 7.9) \cdot 10^{-4}$ cpd/kg/keV for single-hit and multiple-hits residual rates, respectively. Thus, a 6.3 σ C.L. evidence of annual modulation is present in the single-hit residuals (events class to which the WIMP-induced recoils belong), while it is absent in the multiple-hits residual rate (event class to which only background events belong). Since the same identical hardware and the same identical software procedures have been used to analyse the two classes of events, the obtained result offers an additional strong support for the presence of Dark Matter particles in the galactic halo further excluding any side effect either from hardware or from software procedures or from background.

at LNGS by several authors with different techniques over more than 15 years; in addition, as widely known, it cannot satisfy all the peculiarities of the signature.
Conclusion. In conclusion, the presence of an annual modulation in the single-hit events residual rate in the lowest energy interval (2 – 6) keV satisfying all the features expected for a WIMP component in the galactic halo is supported by the data of the seven annual cycles at 6.3 $\sigma$ C.L.. This is the experimental result of DAMA/NaI. It is model independent; no other experiment whose result can be directly compared with this one is available so far in the field of Dark Matter investigation.

4 Corollary result: quests for a candidate particle in some model frameworks with the data of the seven annual cycles

On the basis of the obtained model independent result, corollary investigations can also be pursued on the nature and coupling of the WIMP candidate. This latter investigation is instead model dependent and – considering the large uncertainties which exist on the astrophysical, nuclear and particle physics assumptions and on the parameters needed in the calculations – has no general meaning (as it is also the case – as mentioned above – of exclusion plots and of the WIMP parameters evaluated in indirect search experiments). Thus, it should be handled in the most general way as we have preliminarily pointed out with time in the past [17–24] and we have discussed in some specific details in ref. [5]; other efforts on this topic are also in progress. Candidates, kinds of WIMP couplings with ordinary matter and implications, cross sections, nuclear form factors, spin factors, scaling laws, halo models, priors, etc. are discussed in details in ref. [5] and we invite the reader to this reference since these arguments are necessary to correctly understand the results obtained in corollary quests and the real validity of any claimed model dependent comparison in the field. The results presented in ref. [5] and summarised here are, of course, not exhaustive of the many possible
scenarios which at present level of knowledge cannot be disentangled. Some of the open questions are: i) which is the right nature for the WIMP particle; ii) which is its right couplings with ordinary matter (mixed SI&SD, purely SI, purely SD or preferred inelastic); iii) which are the right form factors and related parameters for each target nucleus; iv) which is the right spin factor for each target nucleus (some nuclei are disfavoured to some kinds of interactions; for example, in case of an interaction with SD component even a nucleus sensitive in principle to SD interaction could be blinded by the spin factor if unfavoured by the $\theta$ value); v) which are the right scaling laws (let us consider as an example that even in a MSSM framework with purely SI interaction the scenario could be drastically modified as discussed recently in ref. [27]); vi) which is the right halo model and related parameters; vii) which are the right values of the experimental parameters within their uncertainties; etc. As an example, we remind that not only large differences in the measured rate can be expected when using target nuclei sensitive to the SD component of the interaction (such as e.g. $^{23}$Na and $^{127}$I) with respect to those largely insensitive to such a coupling (such as e.g. $^{nat}$Ge and $^{nat}$Si), but also when using different target nuclei although all – in principle – sensitive to such a coupling (compare e.g. the Xenon and Tellurium cases with the Sodium and Iodine cases) [5].

In the following some of the results discussed for some of the many possible model dependent quests for a WIMP candidate are briefly reminded [5]. In particular, they have been obtained from the data collected during all the seven annual cycles, considering the halo models summarized in [24,5] for three of the possible values of the local velocity $v_0$: 170 km/s, 220 km/s and 270 km/s. The escape velocity has been maintained at the fixed value: 650 km/s. It is worth to note that the present existing uncertainties on the knowledge of the escape velocity can play a relevant role in evaluating allowed regions (and corresponding best fit values for WIMP mass and cross section) e.g. in the cases of preferred inelastic scattering with target-nuclei).

---

6 Several candidates fulfill the cosmological and particle Physics requirements necessary in order to be considered as a Dark Matter candidate particle: not only the neutralino foreseen in the supersymmetric theories, but also a heavy neutrino of a 4th family (there is still room for it as reported in literature), the sneutrino in the scenario described by [14] (providing – through the transition from lower to upper mass eigenstate – preferred inelastic scattering with target-nuclei), the “mirror” Dark Matter [26], etc.. Moreover, in principle whatever Weakly Interacting, neutral, (quasi-)stable and Massive (whose acronym is WIMP) particle, even not yet foreseen by a theory, can be a suitable candidate. As regards in particular the neutralino, we note that the theories have not stringent predictive capability for its cross sections and for its mass because of the large number of free parameters in the theory and of the several assumptions required; thus, e.g. the expectations for its nuclear cross sections span over several orders of magnitude as it can also be seen in literature. In addition, we take this occasion to remind that the neutralino has both SI and SD couplings with the ordinary matter.

7 We remind that $\tg\theta = a_n/a_p$ is the ratio between the WIMP-neutron and the WIMP-proton effective SD coupling strengths, $a_n$ and $a_p$, respectively [22,5]; $\theta$ is defined in the $[0,\pi)$ interval.
elastic WIMPs and of light mass WIMP candidates; its effect would be instead marginal at large WIMP masses. The possible scenarios have been exploited for those halo models in some discrete cases including some of the uncertainties which exist in the parameters of the used nuclear form factors and in the quenching factors; for the details see ref. [5]. The results summarised here are not exhaustive of the many scenarios possible at present level of knowledge: e.g. for some other recent ideas see the already quoted [15,27].

For simplicity, here the results of these corollary quests for a candidate particle are presented in terms of allowed regions obtained as superposition of the configurations corresponding to likelihood function values distant more than 4σ from the null hypothesis (absence of modulation) in each of the several (but still a limited number) of the possible model frameworks considered here. Obviously, larger sensitivities than those reported in the following figures would be reached when including the effect of other existing uncertainties on the astrophysical, nuclear and particle Physics assumptions and related parameters; similarly, the set of the best fit values would also be enlarged as well.

As well known, DAMA/NaI is intrinsically sensitive both to low and high WIMP mass having both a light (the $^{23}$Na) and a heavy (the $^{127}$I) target-nucleus; in previous corollary quests WIMP masses above 30 GeV (25 GeV in ref. [17]) have been presented [18,20,22–24] for few (of the many possible) model frameworks. However, that bound holds only for neutralino when supersymmetric schemes based on GUT assumptions are adopted to analyse the LEP data [28]. Thus, since other candidates are possible and also other scenarios can be considered for the neutralino itself as recently pointed out, the present model dependent lower bound quoted by LEP for the neutralino in the supersymmetric schemes based on GUT assumptions (37 GeV [32]) is simply marked in the following figures. It is worth to note that when this mass limit is adopted, it selects the WIMP-Iodine elastic scattering as dominant because of the used scaling laws and of kinematical arguments. Finally, the prior from DAMA/NaI-0 has properly been considered as well.

**WIMPs with mixed SI&SD interaction.** The most general scenario of WIMP nucleus elastic interaction, to which the DAMA/NaI target nuclei are fully sensitive, is the one where both the SI and the SD components of the cross section are present. Thus, as first we introduce here the case for a candidate with both SI and SD couplings to ordinary matter [5] similarly as we did in the past also in ref. [22] on partial exposure. In this general scenario the space of the free parameters is a 4-dimensional volume defined by $m_W$, $\xi\sigma_{SI}$, $\xi\sigma_{SD}$ and $\theta$ (which varies from 0 to $\pi$). Thus, the general solution would be a four dimensional allowed volume for each considered model framework. Since the graphic representation of this allowed volume is quite difficult, we only show in Fig. 4 the obtained regions in the plane $\xi\sigma_{SI}$ vs $\xi\sigma_{SD}$ for some of the possible $\theta$ and

---

8 In fact, when the assumption on the gaugino-mass unification at GUT scale is released neutralino masses down to $\approx 6$ GeV are allowed [29–31].

9 $\xi$ ($\xi \leq 1$) is defined here as the fractional amount of local WIMP density.
Results from DAMA/NaI and perspectives for DAMA/LIBRA

Fig. 4. Case of a WIMP with mixed SI&SD interaction in the given model frameworks. Coloured areas: example of slices (of the allowed volume) in the plane $\xi \sigma_{SI}$ vs $\xi \sigma_{SD}$ for some of the possible $m_W$ and $\theta$ values. Inclusion of other existing uncertainties on parameters and models would further extend the regions; for example, the use of more favourable form factors and/or of more favourable spin factors than the considered ones would move them towards lower cross sections. For details see [5].

$m_W$ values in the model frameworks considered here. In particular, we report just four couplings, which correspond to the following values of the mixing angle $\theta$: i) $\theta = 0$ (a$_n$ = 0 and a$_p$ $\neq$ 0 or $|a_p| >> |a_n|$) corresponding to a particle with null SD coupling to neutron; ii) $\theta = \pi/4$ (a$_p$ = a$_n$) corresponding to a particle with the same SD coupling to neutron and proton; iii) $\theta = \pi/2$ (a$_n$ $\neq$ 0 and a$_p$ = 0 or $|a_n| >> |a_p|$) corresponding to a particle with null SD couplings to proton; iv) $\theta = 2.435$ rad ($\frac{a_p}{a_n}$ = -0.85) corresponding to a particle with SD coupling through $Z_0$ exchange. The case $a_p = -a_n$ is nearly similar to the case iv).

From the given figures it is clear that at present either a purely SI or a purely SD or a mixed SI&SD configurations are supported by the experimental data of the seven annual cycles.

**WIMPs with dominant SI interaction.** Generally, the case of purely SI coupled WIMP is mainly considered in literature. In fact, often the spin-independent interaction with ordinary matter is assumed to be dominant since e.g. most of the used target-nuclei are practically not sensitive to SD interactions (as on the contrary $^{23}$Na and $^{127}$I are) and the theoretical calculations are even much more complex and uncertain.
Thus, following an analogous procedure as for the previous case, we have exploited for the same model frameworks the purely SI scenario. In this case the free parameters are two: $m_W$ and $\xi\sigma_{SI}$.

![Diagram](image)

Fig. 5. On the left: Case of a WIMP with dominant SI interaction for the given model frameworks. Region allowed in the plane $(m_W, \xi\sigma_{SI})$. The vertical dotted line represents a bound in case of a neutralino candidate when supersymmetric schemes based on GUT assumptions are adopted to analyse the LEP data; the low mass region is allowed for neutralino when other schemes are considered and for every other WIMP candidate; see text. While the area at WIMP masses above 200 GeV is allowed only for few configurations, the lower one is allowed by most configurations (the colored region gathers only those above the vertical line) [5]. The inclusion of other existing uncertainties on parameters and models would further extend the region; for example, the use of more favourable SI form factor for Iodine alone would move it towards lower cross sections. On the right: Example of the effect induced by the inclusion of a SD component different from zero on allowed regions given in the plane $\xi\sigma_{SI}$ vs $m_W$. In this example the Evans’ logarithmic axisymmetric $C^2$ halo model with $v_0 = 170$ km/s, $\rho_0$ equal to the maximum value for this model and a given set of the parameters’ values (see [5]) have been considered. The different regions refer to different SD contributions for the particular case of $\theta = 0$: $\sigma_{SD} = 0$ pb (a), 0.02 pb (b), 0.04 pb (c), 0.05 pb (d), 0.06 pb (e), 0.08 pb (f). Analogous situation is found for the other model frameworks.

In Fig. 5 - left the region allowed in the plane $m_W$ and $\xi\sigma_{SI}$ for the considered model frameworks is reported. The configurations below the vertical line are of interest for neutralino when the assumption on the gaugino-mass unification at GUT scale is released and for every other kind of WIMP candidate. As shown in Fig. 5 - left, also WIMP masses above 200 GeV are allowed for some configurations; details can be found in ref. [5]. Of course, best fit values of cross section and WIMP mass span over a large range in the considered frameworks.

Let us now point out, in addition, that configurations with $\xi\sigma_{SI}$ even much lower than those shown in Fig. 5 - left are accessible in case an even small SD contribution is present in the interaction. This possibility is clearly pointed out in Fig. 5 - right where an example of allowed regions in the plane $(m_W, \xi\sigma_{SI})$ corresponding to different SD contributions is reported for the case $\theta = 0$. As it can be seen, increasing the SD contribution the allowed regions involve SI cross sections much lower than $10^{-6}$ pb. It can be noted that for $\sigma_{SD} \geq 0.08$ pb the annual modulation effect observed is also compatible – for $m_W \approx 40 – 75$ GeV.
– with a WIMP candidate with no SI interaction at all. Analogous situation is found for the other model frameworks.

**WIMPs with dominant SD interaction.** Let us now focus on the case of a candidate with purely SD coupling to which DAMA/NaI is – as mentioned –

![Graph showing region allowed in the plane (m_W, \(\xi\sigma_{SD}\)]; here \(\theta = 2.435\), \(Z_0\) coupling, \(\theta\) is defined in the \([0, \pi]\) range). For the definition of the vertical line and of the coloured area see previous figure caption; see also text. Inclusion of other existing uncertainties on parameters and models (as discussed in ref. [5]) would further extend the SD allowed regions. For example, the use of more favourable SD form factors and/or more favourable spin factors would move them towards lower cross sections. Values of \(\xi\sigma_{SD}\) lower than those corresponding to these allowed regions are possible also e.g. in case of an even small SI contribution (see ref. [5]).

Fig. 6. Case of a WIMP with dominant SD interaction in the given model frameworks. An example of the region allowed in the plane \((m_W, \xi\sigma_{SD})\); here \(\theta = 2.435\), \(Z_0\) coupling, \(\theta\) is defined in the \([0, \pi]\) range). For the definition of the vertical line and of the coloured area see previous figure caption; see also text. Inclusion of other existing uncertainties on parameters and models (as discussed in ref. [5]) would further extend the SD allowed regions. For example, the use of more favourable SD form factors and/or more favourable spin factors would move them towards lower cross sections. Values of \(\xi\sigma_{SD}\) lower than those corresponding to these allowed regions are possible also e.g. in case of an even small SI contribution (see ref. [5]).

fully sensitive.

When the SD component is different from zero, a very large number of possible configurations is available. In fact, in this scenario the space of free parameters is a 3-dimensional volume defined by \(m_W, \xi\sigma_{SD}\) and \(\theta\) (which can vary from 0 to \(\pi\)). Here, just as an example we show the results obtained only for a particular coupling, which correspond to a mixing angle \(\theta = 2.435\) (\(Z_0\) coupling); see Fig. 6; other configurations are possible varying the \(\theta\) value. The area at WIMP masses above 200 GeV is allowed for low local velocity and all considered sets of parameters by the Evans’ logarithmic \(C_2\) co-rotating halo model [5]. Moreover, the accounting for the uncertainties e.g. on the form factors and/or on the spin factors as well as different possible formulations of the SD form factors would extend the allowed regions, e.g. towards lower \(\xi\sigma_{SD}\) values. Finally, \(\xi\sigma_{SD}\) lower than those corresponding to the regions shown in Fig. 6 are possible also e.g. in case of an even small SI contribution (see ref. [5]).

**WIMPs with preferred inelastic interaction.** An analysis considering the same model frameworks has been carried out for the case of WIMPs with preferred inelastic interaction [14] as we did also in the past in ref. [23] on partial exposure.

In this inelastic Dark Matter scenario an allowed volume in the space \((\xi\sigma_p, m_W, \delta)\) is obtained; \(\delta\) is the mass splitting of the WIMP particle which can be excited following an inelastic interaction [14,23,5]. For simplicity, Fig. 7 shows slices of such an allowed volume at some given WIMP masses. There the super-
positions of the allowed regions obtained, when varying the model framework within the considered set [5], are shown for each $m_W$. We remind that in these calculations $v_{esc}$ has been assumed at fixed value (as in the previous cases), while its present uncertainties can play a significant role in this scenario of WIMP with preferred inelastic scattering.

Conclusion. In this section we have briefly summarized some quests for the candidate particle in some of the many possible scenarios. We further stress that, although several scenarios have been investigated, these corollary analyses are not exhaustive at all because of the present poor knowledge on many astrophysical, nuclear and particle Physics needed assumptions; moreover, additional scenarios can also be possible as also shown e.g. by some recent papers appeared in literature. Other model dependent quests are already under consideration.

5 The second generation: DAMA/LIBRA

In 1996 a ton set-up was proposed by Bernabei et al.; as a consequence a new R&D for NaI(Tl) radiopurification has been carried out and the second generation set-up DAMA/LIBRA ($\sim$250 kg NaI(Tl)) has been funded and realised as an intermediate step. This R&D with Crismatec-St. Gobain company has exploited for the first time new chemical/physical radiopurification procedures in NaI and TlI powders already selected for radiopurity. In addition, new selected materials and set-up components as well as new protocols have been employed for building DAMA/LIBRA.
In 2002 ended the production of detectors and of new parts of the installation for DAMA/LIBRA. Thus, after July 2002 – at the completion of its data taking – DAMA/NaI was fully dismounted and the installation of the new DAMA/LIBRA started. The experimental site as well as many components of the installation itself were implemented (environment, shield of PMTs, wiring, HP Nitrogen system, cooling water of air conditioner, electronics and DAQ, etc...). Before the installation, all the Cu parts were chemically etched following a devoted protocol and maintained in HP Nitrogen atmosphere. In addition, all the procedures performed during the dismounting of DAMA/NaI and the installation of DAMA/LIBRA were carried out in HP Nitrogen atmosphere. This was realised by using a Scuba system (a self-contained underwater breathing apparatus) modified in order to avoid that the entire breath is expelled into the surrounding air when the operator exhales; the air cylinders were kept five meters away and the output line was two meters long.

Fig. 8. DAMA/LIBRA: a view of the detectors inside the inner Cu box at end of installation (photo taken in HP Nitrogen atmosphere). All the used materials have been deeply selected for radiopurity.

The new DAMA/LIBRA, having an exposed mass of \(\simeq 250 \text{ kg}\), an higher overall radiopurity and improved performances, offers an increased experimental sensitivity to further investigate the DAMA/NaI observed effect and to improve investigations on the nature of the candidate particle trying to disentangle among different possible astrophysical, nuclear and particle Physics models as well as other new possible scenarios. See just as an example of new ideas the case of the mirror Dark Matter [26], the case of a contribution to the dark halo from the Sagittarius Dwarf Tidal Stream [15], the case of possible different nuclear scaling laws even for the neutralino candidate in MSSM [27], etc. Moreover, the low background DAMA/LIBRA offers a powerful tool for the Dark Matter investigation in the future since it is e.g. sensitive: i) both to low (through interaction on \(^{23}\text{Na}\)) and to high (through interaction on \(^{127}\text{I}\)) mass Dark Matter particles; ii) both to mixed SI&SD, to purely SI, to purely SD couplings and to preferred inelastic scattering as well as to other possible kind of Dark Matter candidates (e.g. mirror Dark Matter).

DAMA/LIBRA has started the preliminary data taking on March 2003 and it has been planned to run for several years. At present a new R&D effort toward
the possible NaI(Tl) ton set-up has been funded and related works have already been started.

6 Conclusion

DAMA/NaI has been a pioneer experiment running at LNGS for about a decade and investigating as first the WIMP annual modulation signature with suitable exposed mass, sensitivity and control of the running parameters. During seven independent experiments of one year each one, it has pointed out the presence of a modulation satisfying the many peculiarities of a WIMP induced effect, reaching an evidence at 6.3 \( \sigma \) C.L.. No other experiment has so far been in position to give a result directly comparable in a model independent way with that of DAMA/NaI. As a corollary, it has also pointed out the complexity of the quest for a WIMP candidate because of the present poor knowledge on the many astrophysical, nuclear and particle physics aspects.

After the completion, on July 2002, of the DAMA/NaI data taking, the second generation DAMA/LIBRA set-up (\( \simeq 250 \) kg mass) has been installed and preliminarily put in operation, as a result of continuous efforts by the DAMA collaboration toward the creation of ultimate radiopure NaI(Tl). DAMA/LIBRA, having a larger exposed mass and an higher overall radiopurity, will significantly contribute in the incoming years to the further understanding of the field. Presently, new R&D efforts toward a possible NaI(Tl) ton set-up have been funded and related works have already been started.
