Subgraph Sparsification and Nearly Optimal Ultrasparsifiers

Alexandra Kolla*  Yury Makarychev†  Amin Saberi ‡  Shang-Hua Teng §

Abstract

We consider a variation of the spectral sparsification problem where we are required to keep a subgraph of the original graph. Formally, given a union of two weighted graphs $G$ and $W$ and an integer $k$, we are asked to find a $k$-edge weighted graph $W_k$ such that $G + W_k$ is a good spectral sparsifier of $G + W$. We will refer to this problem as the subgraph (spectral) sparsification. We present a nontrivial condition on $G$ and $W$ such that a good sparsifier exists and give a polynomial time algorithm to find the sparsifier.

As a significant application of our technique, we show that for each positive integer $k$, every $n$-vertex weighted graph has an $(n-1+k)$-edge spectral sparsifier with relative condition number at most $\frac{n}{k} \log n \tilde{O}(\log \log n)$ where $\tilde{O}()$ hides lower order terms. Our bound is within a factor of $\tilde{O}(\log \log n)$ from optimal. This nearly settles a question left open by Spielman and Teng about ultrasparsifiers, which is a key component in their nearly linear-time algorithms for solving diagonally dominant symmetric linear systems.

We also present another application of our technique to spectral optimization in which the goal is to maximize the algebraic connectivity of a graph (e.g. turn it into an expander) with a limited number of edges.

1 Introduction

Sparsification is an important technique for designing efficient graph algorithms, especially for dense graphs. Informally, a graph $\tilde{G}$ is a sparsifier of $G$ if they are similar in a particular measure (which is important to the application that one has in mind), and that $\tilde{G}$ has linear or nearly linear number of edges. Various notions of graph approximation and sparsification have been considered in the literature. For example, Chew’s [6] spanners (for shortest path planning) have the property that the distance between every pair of vertices in $\tilde{G}$ is approximately the same as in $G$. Benczur and Karger’s [4] cut-sparsifiers (for cuts and flows) have the property that the weight of the boundary of every set of vertices is approximately the same in $G$ as in $\tilde{G}$.

In this paper, we will mainly be interested in the spectral notion of graph similarity introduced by Spielman and Teng [18], [20]: we say that a weighted undirected graph $H$ is a $\kappa$-approximation of another $G$ if for all $x \in \mathbb{R}^V$,

$$x^T L_G x \leq x^T \tilde{L}_G x \leq \kappa x^T L_G x$$

where for a weighted undirected graph $G$, $L_G$ is the Laplacian matrix of $G$ defined as the following: For each $L_G(i, i)$ is equal to the sum of weights of all edges incident to vertex $i$ and for $i \neq j$, $L_G(i, j) = -w_{i,j}$, where $w_{i,j}$ is the weight on edge $(i, j)$.

In [18, 20], the following spectral sparsification problem is considered. Given a weighted graph $G = (V, E, w)$, an integer $m \leq |E|$, and $\kappa \geq 1$, find a graph $\tilde{G} = (V, \tilde{E}, \tilde{w})$ such that $|\tilde{E}| \leq m$ and $\tilde{G}$ is a $\kappa$-approximation of $G$. We will refer to this problem and its corresponding optimization problem as the SPECTRAL SPARSIFICATION. Spielman and Teng showed that every weighted graph has a nearly linear-sized spectral sparsifier and gave a nearly linear-time algorithm for computing such a sparsifier. Recently, Batson, Spielman, and Srivastava [3] gave a beautiful, polynomial-time construction to produce a linear-sized spectral sparsifier.

In this paper, we introduce a variation of the spectral sparsification problem which we will refer to as the SUBGRAPH SPARSIFICATION. In our version, we are given two weighted graphs $G$ and $W$, an integer $k$ and $\kappa \geq 1$. The goal is to find a $k$-edge weighted graph $W_k$ such that $(G + W_k)$ is a $\kappa$-approximation of $(G + W)$. The challenge in the new version of the sparsification problem is that we have to respect part of the graph, i.e., $G$, and only modify part of graph given in $W$.

As the main technical contribution of the paper, we give a nontrivial condition about $G$ and $W$ such that a good sparsifier exists. Our proof critically uses the intuition of Batson, Spielman, and Srivastava [3], that uses potential functions that guide an incremental process for selecting the edges of the sparsifier. We will refer to that as as the BSS process. We have enhanced their approach with new understanding about subspace sparsification and spectral approximation.

Our challenge, at high level, is the following. The BSS process uses two carefully chosen barriers (see Section 2) so that at each step, all eigenvalues can be kept far enough from these barriers. They have $\Theta(n)$ edges to select. So they consider the entire $n$-dimensional space and have step size $\Theta(1/n)$ on these barriers.

On the other hand, we can only add $k$ edges, where $k$ can be arbitrarily smaller than $n$. The addition of each edge can only increase smallest eigenvalue to the second smallest eigenvalue. Therefore the addition of $k$ edges can only improve the subspace defined by the $k$ smallest eigenvalue. Now, the critical part of the argument is that to build a good sparsifier, we need to ensure that the addition of the edges does not increase the high spectra by too much. So in our incremental process, we need to keep track of two subspaces, a fixed one defined by the $k$ smallest eigenvalues and a floating one defined by the higher spectra.
We developed an analysis for performing spectral analysis in the projection of a sequence of two subspaces, which might be interesting on its own right. Our analysis also provide a nice example for using majorization.

Our ability to conduct sparsification on a subgraph enables us to obtain improved results for a few problems on spectral optimization. The first application that we consider is the problem of finding ultrasparsifiers as defined in Spielman and Teng [18]. For parameters $\kappa \geq 1$ and $k \geq 1$, a weighted undirected graph $U$ is a $(\kappa, k)$-ultrasparsifier of another graph $G$, if $U$ has at most $n - 1 + k$ edges, and $L_U \preceq L_G \preceq \kappa \cdot L_U$. Ultrasparsifiers are essential in the application of the preconditioning techniques for solving linear systems [18, 20]. It has been shown in [18] that every weighted undirected graph $G$ has a $(\frac{n}{k} \log^O(1) n, k)$ ultrasparsifiers, for any $k$. As a significant application of our subgraph sparsification technique, we show that for every positive integer $k$, every $n$-vertex weighted graph has a $(\frac{k}{2} \log n \tilde{O}(\log \log n), k)$-ultrasparsifier. Our bound is within a factor of $\tilde{O}(\log \log)$ from the optimal. This new result nearly settles a question about ultrasparsifiers left open by Spielman and Teng.

At high level, our solution to ultrasparsification is quite simple, once we have our subgraph sparsification result. Given a weighted graph $G$, we first construct a low-stretch spanning tree $[2, 7, 1]$ $T$ of $G$. We then apply an elegant result of Spielman and Woo [21] which states that the sum of the relative condition numbers of $L_G$ and $L_T$ is equal to the total stretch to embed $G$ onto $T$. We will also use Spielman–Woo’s tail distribution bound on the number of relative eigenvalues of $L_G$ and $L_T$ that are larger than a given parameter.

Algorithmically, we start with the best available [1] low-stretch spanning tree $T$ of $G$ whose total stretch is $n \log n \tilde{O}(\log \log n)$. We then consider the subgraph sparsification problem defined by $T$ and $W = \frac{k}{n \log n \tilde{O}(\log \log n)} G$. We apply the structure theorem of Spielman and Woo [21] to show that $(T, W)$ satisfy our condition for subgraph sparsification and apply our result to show that there exists a $k$-edge weighted graph $W_k$ whose edges are in $W$ such that $T + W_k$ is a spectral approximation of $T + W$. It is then not hard to prove that $T + W_k$ is an a $(\frac{k}{2} \log n \tilde{O}(\log \log n), k)$-ultrasparsifier.

As another application of our technique on subgraph sparsification, we consider the following spectral optimization problem studied in [5]: Given a graph $G$ and a parameter $k$, we are asked to find $k$ edges amongst a set of candidate edges to add to $G$ so as to maximize its algebraic connectivity. Algebraic connectivity has emerged as an important parameter for measuring the robustness and stability of a network and is an essential factor in the performance of various search, routing and information diffusion algorithms.

The spectral optimization considered in this paper is known to be NP-hard [15] and no approximation guarantee for it was known prior to our work. We give an SDP-based approximation algorithm for the problem. Our techniques for subgraph sparsification enable us to develop a novel rounding scheme in order to find a combinatorial solution. Since the integrality gap of the SDP is unbounded, our analysis involves adding a separate upper bound, which is roughly the $k$-th largest eigenvalue of the Laplacian of $G$ to approximate the optimum solution.

## 2 Preliminaries

**Matrix Notation and Definitions.** We denote the Laplacian of a graph $G$ by $L_G$. For brevity, we write $G_1 \preceq G_2$ to denote $L_{G_1} \preceq L_{G_2}$. For an $n \times n$ matrix $A$, let $\lambda_{\min}(A) \equiv \lambda_1(A) \leq \lambda_2(A) \leq \cdots \leq \lambda_n(A) \equiv \lambda_{\max}(A)$ be the set of eigenvalues in the increasing order. Let $A^\dagger$ be the pseudoinverse
of $A$. If $A$ is symmetric, $A^\dagger$ is also symmetric and $AA^\dagger = A^\dagger A = P_{\text{im}(A)}$, where $P_{\text{im}(A)}$ is the orthogonal projection on $\text{im}(A)$. Let $A \bullet B \equiv \text{tr} A^T B$ be the Froebenius product of matrices $A$ and $B$. We define the condition number of a non-singular matrix $A$ as $\kappa = \|A\|\|A^{-1}\|$, which is equal to $\lambda_{\text{max}}(A)/\lambda_{\text{min}}(A)$ if $A$ is a (symmetric) positive definite matrix. For positive definite matrices $A, B$ with $\text{Im} A = \text{Im} B$, we define the relative condition number as

$$\kappa(A, B) = \max_{x \notin \ker B} \frac{x^T A x}{x^T B x} \cdot \max_{x \notin \ker A} \frac{x^T B x}{x^T A x}.$$

**Ultrasparsifiers.** We say that a graph is $k$–ultra-sparse if it has at most $n - 1 + k$ edges. We note that a spanning tree is 0–ultra-sparse. A $(\kappa, k)$ ultra-sparsifier of a graph $G = (V, E, w)$ is a $k$–ultra-sparse subgraph of $G$ such that $U \preceq G \preceq \kappa \cdot U$ [18].

## 3 Matrix Sparsifiers

In this section, we prove an analog of the sparsification theorem of Batson, Spielman, and Srivastava [3].

**Definition 3.1.** (Graph Patch) Let $G$ be a (weighted) graph. A graph $W$ on the vertices of $G$ is a $(k, T, \lambda^*)$-patch for $G$ if the following properties hold:

1. $\lambda_{k+1}(L_G L_{G+W}^\dagger) \equiv \lambda_{k+1}((L_{G+W}^\dagger)^{1/2} L_G (L_{G+W}^\dagger)^{1/2}) \geq \lambda^*$;
2. $\text{tr}(L_W L_{G+W}^\dagger) \leq T$.

We prove that for every patch, there exists a “patch sparsifier” supported on $O(k)$ edges. Specifically, we prove the following theorem.

**Claim 3.2.** Let $W = (V, E_W, \{w_e\}_{e \in E_W})$ be a $(k, T, \lambda^*)$-patch for $G$ with edge weights $w_e$ and $N \geq 8k$. Then there is a weighted graph $W_k = (V, E_{W_k}, \{\tilde{w}_e\}_{e \in E_{W_k}})$ with edge weights $\tilde{w}_e$ such that

1. $W_k$ has at most $N$ edges; $E_{W_k} \subseteq E_W$.
2. $c_1 \min(N/T, 1) \lambda^* L_{G+W} \preceq L_{G+W_k} \preceq c_2 L_{G+W}$, for some absolute constants $c_1$ and $c_2$.
3. The total weight of edges, $\sum_{e \in E_{W_k}} \tilde{w}_e$, is at most $\min(1, N/T) \sum_{e \in E_W} w_e$.

We say that $W_k$ is a patch sparsifier of $W$ with respect to $G$.

The claim will follow immediately from the following theorem, which is of independent interest. We will also show another (related) application of this theorem in Section 5.

**Theorem 3.3.** Suppose we are given a positive definite $n \times n$ matrix $X$ and a sequence of matrices $Y_i = v_i v_i^T$ ($i = 1, \ldots, m$) with

$$X + \sum_{i=1}^m Y_i = M^*,$$

we have $\lambda_{k+1}(L_G L_{G+W}^\dagger) = \lambda_{k+1}((L_{G+W}^\dagger)^{1/2} L_G (L_{G+W}^\dagger)^{1/2})$, since $\lambda_i(AB) = \lambda_i(BA)$ for every two square matrices $A$ and $B$.
and $\lambda_{\text{max}}(M^*) \leq 1$. Additionally, suppose each matrix $Y_i$ has cost $c_i$ and $\sum_{i=1}^{m} c_i = 1$. Let $\lambda^* = \lambda_{k+1}(X)$, and $T = \{ \text{tr}(M^* - X) \}$. Then for every $N > 8k$ there exists a set of weights $w_i$ with $|\{ w_i : w_i \neq 0 \}| = N$ such that the matrix $M = X + \sum_{i=1}^{m} w_i Y_i$ satisfies,

$$c_1 \min(N/T, 1) \cdot \lambda^* \cdot \lambda_{\text{min}}(M^*) \leq \lambda_{\text{min}}(M) \leq \lambda_{\text{max}}(M) \leq c_2,$$

where $c_1$ and $c_2$ are some absolute constants, and $\sum_{i=1}^{m} w_i c_i \leq \min(1, N/T)$.

**Proof Overview.** Our proof closely follows the approach of Batson, Spielman, and Srivastava [3]. We construct matrix $M$ in $N$ steps; at each step we choose an index $i$ and weight $w_i$ and add $w_i Y_i$ to the sum $X + \sum_{i=1}^{m} w_i Y_i$. Recall that Batson, Spielman, and Srivastava define two “barriers” $l$ and $u$ and maintain the property that all eigenvalues of $M$ lie between $l$ and $u$. At each step, they increase $l$ and $u$ and update matrix $M$ so that this property still holds. Finally, the ratio between $u$ and $l$ becomes very close to 1, which means that $\lambda_{\text{min}}(M)$ is very close to $\lambda_{\text{max}}(M)$. During this process, they keep track not only of the smallest and largest eigenvalues of $M$ but of all $n$ eigenvalues to avoid accumulation of eigenvalues in neighborhoods of $l$ and $u$. To this end, they define two potential functions, the lower potential function $\Phi_l(M) = \sum_{i=1}^{n} \frac{1}{\lambda_i(M) - l}$ and the upper potential function $\Phi_u(M) = \sum_{i=1}^{n} \frac{1}{u - \lambda_i(M)}$, and then ensure that $\Phi_l(M)$ and $\Phi_u(M)$ do not increase over time. That guarantees that all eigenvalues of $M$ stay far away from $l$ and $u$.

In our proof, however, we cannot keep an eye on all eigenvalues. After each step, only one eigenvalue increases, and thus we need $\theta(n)$ steps to increase all eigenvalues participating in the definition of $\Phi_l(M)$. But our goal is to “patch” $X$ in roughly $k$ steps. So we focus our attention only on $k$ smallest and $T$ largest eigenvalues.

Let $S$ be the eigenspace of $X$ corresponding to $k$ smallest eigenvalues, and $P_S$ be the projection onto $S$. We define the lower potential function as follows,

$$\Phi_l(A) = \text{tr}(P_S(A - lI)P_S)^\dagger = \sum_{i=1}^{k} \frac{1}{\lambda_i(A|_S) - l},$$

where $A|_S$ denotes the restriction of $A$ to the space $S$ ($A|_S$ is a $k \times k$ matrix). Note that the space $S$ is fixed, and the eigenvector corresponding to the smallest eigenvalue will not necessarily lie in $S$ after a few steps. We want to ensure that after $N$ steps,

$$\sum_{i=1}^{m} w_i Y_i|_S \succeq c \min(N/T, 1) \sum_{i=1}^{m} Y_i|_S = c \min(N/T, 1)(M^* - X)|_S,$$

or in other words, $\lambda_{\text{min}}((Z(\sum_{i=1}^{m} w_i Y_i)Z)|_S) \geq c \min(N/T, 1)$, where $Z = ((P_S(M^* - X)P_S)^\dagger)^{1/2}$. To this end, we show how to update $M$ and $l$ so that $\Phi_l(Z(\sum_{i=1}^{m} w_i Y_i)Z)$ does not increase, and $l$ equals $c \min(N/T, 1)$ after $N$ steps. It remains to lower bound $\lambda_{\text{min}}(M)$ in the entire space. We know that all eigenvalues of $X$ (and therefore, of $M$) in $S^\perp$ are at least $\lambda^*$. We show that that together with an upper bound on $\lambda_{\text{max}}(M)$ implies that $\lambda_{\text{min}}(M) \geq c_1 \min(N/T, 1) \cdot \lambda^* \lambda_{\text{min}}(M^*)$ (the product of the lower bounds on $\lambda_{\text{min}}$ in spaces $S$ and $S^\perp$ divided by the upper bound on $\lambda_{\text{max}}$).

Similarly, we amend the definition of the upper potential function. Since we need to bound $\lambda_{\text{max}}$ in the entire space, we cannot restrict $\Phi_u(M)$ to a fixed subspace. For a matrix $A$, we consider the eigenspace of $A$ corresponding to its largest $T$ eigenvalues. Denote it by $L_A(A)$; denote the
projection onto $L(A)$ by $P_{L(A)}$. Then

$$
\Phi^u(A) = \text{tr}(P_{L(A)}(uI - A)^{-1}P_{L(A)}) = \text{tr}(P_{L(A)}(uI - A)P_{L(A)})^\dagger = \sum_{i=n-T+1}^{N} \frac{1}{u - \lambda_i(A)}.
$$

Note that both definitions of $\Phi^u(A)$ — in terms of regular inverse and in terms of pseudoinverse — are equivalent since $L(A)$ is an invariant subspace of $A$. However, $\Phi_l(A)$ is not equal to $\text{tr}(P_S(A - lI)^{-1}P_S)$ in general since $S$ is not necessarily an invariant subspace of $A$.

Our algorithm and analysis are similar to those of Batson, Spielman, and Srivastava [3]. However, several complications arise because we are controlling eigenvalues in different subspaces and, moreover, one of these subspaces, $L(A)$, is not fixed.

Let us summarize the proof. We construct the matrix $M$ iteratively in $N$ steps. Let $A^{(q)}$ be the matrix and $w_i^{(q)}$ be the weights after $q$ steps. We define an auxiliary matrix $B^{(q)}$ as $Z(A^{(q)} - X)Z$. We have,

$$
A^{(q)} = X + \sum_i w_i^{(q)}Y_i; \quad B^{(q)} = \sum_i w_i^{(q)}ZY_iZ = Z(A^{(q)} - X)Z.
$$

We will ensure that the following properties hold after each step (for some values of constants $l_0$, $\delta_L$, $u_0$, $\delta_U$, $\epsilon_L$, $\epsilon_U$, which we will specify later).

1. $\Phi_{l_0}(B^{(0)}) \leq \epsilon_L$ and $\Phi^{u_0}(A^{(0)}) \leq \epsilon_U$.

2. Each matrix $A^{(q)}$ and $B^{(q)}$ is obtained by a rank-one update of the previous one:

$$
A^{(q+1)} = A^{(q)} + tY_i; \quad B^{(q+1)} = B^{(q)} + tZY_iZ
$$

for some $i$.

3. Lower and upper potentials do not increase. Namely, for every $q = 0, 1, \ldots, N$,

$$
\Phi^{u_0+(q+1)\delta_U}(A^{(q+1)}) \leq \Phi^{u_0+q\delta_U}(A^{(q)}) \leq \epsilon_U \quad \text{and} \quad \Phi_{l_0+(q+1)\delta_L}(B^{(q+1)}) \leq \Phi_{l_0+q\delta_L}(B^{(q)}) \leq \epsilon_L.
$$

4. At each step $q$, $\lambda_{\min}(B^{(q)}) > l \equiv l_0 + q\delta_L$ and $\lambda_{\max}(A^{(q)}) < u \equiv u_0 + q\delta_U$. In particular, this condition ensures that all terms in the definitions of upper and lower potentials are positive.

5. At each step $q$, the total cost is at at most $q / \max(N, T)$: $\sum w_i^{(q)} \text{cost}_i \leq q / \max(N, T)$.

We present the complete proof in Sections 3.2 and 3.3. In Section 3.2, we first find conditions under which we can update $A^{(q)}$ and $u$ (Lemma 3.10), and $B^{(q)}$ and $l$ (Lemma 3.11). Then we show that both conditions can be simultaneously satisfied (Lemma 3.12). In Section 3.1.2, we prove several theorems that we need later to deal with a non-fixed subspace $L(A)$. Finally, in Section 3.3, we combine all pieces of the proof together.

### 3.1 Some Basic Facts about Matrices

#### 3.1.1 Sherman–Morrison Formula

We use the Sherman–Morrison Formula, which describes the behavior of the inverse of a matrix under rank-one updates. We first state the formula for regular inverse [8], and then we show that a similar expression holds for the pseudoinverse.
Lemma 3.4 (Sherman–Morrison Formula). If $A$ is a nonsingular $n \times n$ matrix and $Y = vv^T$ is a rank-one update, then

$$(A + Y)^{-1} = A^{-1} - \frac{A^{-1}YA^{-1}}{1 + A^{-1} \cdot Y}.$$ 

Lemma 3.5. If $A$ is a symmetric (possibly singular) $n \times n$ matrix, $Y = vv^T$ is a rank-one update, then

$$(A + PYP)^\dagger = A^\dagger - \frac{A^\dagger YA^\dagger}{1 + A^\dagger \cdot Y},$$

where $P$ is the orthogonal projection on $\text{Im}(A)$.

Proof. Let $\bar{v} = Pv$ and $\bar{Y} = PYP = \bar{v}\bar{v}^T$. Note that $A^\dagger YA^\dagger = A^\dagger \bar{Y} A^\dagger$, since $PA^\dagger = P$, and

$$A^\dagger \cdot \bar{Y} = \text{tr} A^\dagger \bar{Y} = \text{tr} A^\dagger (PYP) = \text{tr}(PA^\dagger P)Y = A^\dagger \cdot Y.$$ 

We need to verify that

$$(A + \bar{Y}) \left( A^\dagger - \frac{A^\dagger \bar{Y} A^\dagger}{1 + A^\dagger \cdot Y} \right) = \left( A^\dagger - \frac{A^\dagger \bar{Y} A^\dagger}{1 + A^\dagger \cdot Y} \right) (A + \bar{Y}) = P.$$ 

Since $A$ is a symmetric matrix, $AA^\dagger = A^\dagger A = P$. Since $P^2 = P$, $PYP = \bar{Y}$ and $\bar{Y}A^\dagger \bar{Y} = \bar{v}\bar{v}^T \bar{A} \bar{v}^T = \bar{v}(A^\dagger \cdot \bar{Y}) \bar{v}^T = (A^\dagger \cdot \bar{Y})\bar{Y}$. We calculate,

$$(A + \bar{Y}) \left( A^\dagger - \frac{A^\dagger \bar{Y} A^\dagger}{1 + A^\dagger \cdot Y} \right) = AA^\dagger + \bar{Y} A^\dagger - \frac{P}{Y A^\dagger + \bar{Y} A^\dagger} A^\dagger \cdot \bar{Y} + A^\dagger \cdot \bar{Y}$$

$$= P + \bar{Y} A^\dagger - \frac{(1 + A^\dagger \cdot \bar{Y}) \bar{Y} A^\dagger}{1 + A^\dagger \cdot Y} = P + \bar{Y} A^\dagger - \bar{Y} A^\dagger = P.$$ 

Similarly,

$$(A^\dagger - \frac{A^\dagger \bar{Y} A^\dagger}{1 + A^\dagger \cdot Y})(A + \bar{Y}) = P.$$

3.1.2 Majorization

Lemma 3.6. (Majorization) For every positive semidefinite matrix $A$, every projection matrix $P$, and every $r \in \{1, \ldots, n\}$

$$\sum_{i=n-r+1}^{n} \lambda_i(A) \geq \sum_{i=n-r+1}^{n} \lambda_i(PAP).$$

In particular, $\lambda_{\text{max}}(A) \geq \lambda_{\text{max}}(PAP)$.

Proof. Let $e_1, \ldots, e_n$ be an orthonormal eigenbasis of $A$ so that $e_i$ has eigenvalue $\lambda_i(A)$. Similarly, let $\tilde{e}_1, \ldots, \tilde{e}_n$ be an orthonormal eigenbasis of $PAP$ so that $\tilde{e}_i$ has eigenvalue $\lambda_i(PAP)$. Write

$$\tilde{e}_i = \sum_{j=1}^{n} \langle e_j, \tilde{e}_i \rangle e_j.$$
Note that if \( \lambda_i(PAP) \neq 0 \) then \( \tilde{e}_i \in \text{Im}(PAP) \subseteq \text{Im}(P) \) and \( P\tilde{e}_i = \tilde{e}_i \). Then

\[
\lambda_i(PAP) = \tilde{e}_i^TPAP\tilde{e}_i = \tilde{e}_iA\tilde{e}_i = \sum_{j=1}^{n}\langle e_j, \tilde{e}_i \rangle^2\lambda_j(A).
\]

If \( \lambda_i(PAP) = 0 \) then trivially

\[
\lambda_i(PAP) = 0 \leq \sum_{j=1}^{n}\langle e_j, \tilde{e}_i \rangle^2\lambda_j(A).
\]

Therefore,

\[
\sum_{i=n-r+1}^{n} \lambda_i(PAP) \leq \sum_{i=n-r+1}^{n} \sum_{j=1}^{n}\langle e_j, \tilde{e}_i \rangle^2\lambda_j(A) = \sum_{j=1}^{n} \left( \sum_{i=n-r+1}^{n} \langle e_j, \tilde{e}_i \rangle^2 \right)\lambda_j(A).
\]

That is, \( \sum_{i=n-r+1}^{n} \lambda_j(PAP) \) is at most the sum of \( \lambda_j(A) \) with weights \( \sum_{i=n-r+1}^{n} \langle e_j, \tilde{e}_i \rangle^2 \). The total weight of all \( \lambda_1(A), \ldots, \lambda_n(A) \) is \( r \):

\[
\sum_{i=n-r+1}^{n} \sum_{j=1}^{n} \langle e_j, \tilde{e}_i \rangle^2 = \sum_{i=n-r+1}^{n} \| \tilde{e}_i \|^2 = r.
\]

The weight of each eigenvalue \( \lambda_j(A) \) in the sum is at most 1:

\[
\sum_{i=n-r+1}^{n} \langle e_j, \tilde{e}_i \rangle^2 \leq \sum_{i=1}^{n} \langle e_j, \tilde{e}_i \rangle^2 = 1.
\]

Therefore, the sum does not exceed the sum of the \( r \) largest eigenvalues \( \sum_{i=n-r+1}^{n} \lambda_r(A) \).

**Corollary 3.7.** For every positive semidefinite matrix \( A \), every projection matrix \( P \) and \( u > \lambda_{\max}(A) \), the following inequality holds.

\[
\Phi^u(PAP) = \sum_{i=n-T+1}^{n} \frac{1}{u - \lambda_i(PAP)} \leq \sum_{i=n-T+1}^{n} \frac{1}{u - \lambda_i(A)} = \Phi^u(A) \tag{3}
\]

**Proof.** The statement follows from the Karamata Majorization Inequality. The inequality claims that for every two non-increasing sequences that satisfy (2) and for every increasing convex function \( f \),

\[
\sum_{i=n-k+1}^{n} f(\lambda_i(A)) \geq \sum_{i=n-k+1}^{n} f(\lambda_i(PAP)).
\]

Plugging in \( f(x) = \frac{1}{u-x} \) (defined on \( (0,u) \)), we obtain the desired inequality. \( \square \)

**Lemma 3.8.** Let \( A \) be a positive semidefinite matrix such that \( A \preceq I_n \). Assume \( \text{Tr}(A) \leq r \in \mathbb{N} \). Then for every positive semidefinite matrix \( M \), \( A \cdot M \leq \sum_{i=N-r+1}^{N} \lambda_i(M) \).
Proof. By von Neumann’s inequality [14], $A \cdot M = \text{tr}(AM) \leq \sum_{i=1}^{n} \lambda_i(A)\lambda_i(M)$. Since $\sum_{i=1}^{n} \lambda_i(A) \leq r$ and all $\lambda_i(A) \leq 1$, we can easily see that the above product achieves its maximum when the largest $r$ eigenvalues of $A$ are 1 and the rest are 0. In this case, we have, $A \cdot M \leq \sum_{i=1}^{n} \lambda_i(A)\lambda_i(M) = \sum_{i=n-r+1}^{n} \lambda_i(M)$. \hfill $\square$

As a corollary we get the following result.

Corollary 3.9. Let $X$, $M^*$ and $T$ be as in Theorem 3.3. Then for any positive semidefinite matrix $U$, we have $U \cdot (M^* - X) \leq \sum_{i=n-T+1}^{n} \lambda_i(U)$.

3.2 Barrier Shifts

In this section, we analyze how we can update matrices $A^{(q)}$ and $B^{(q)}$, and increment barriers $l$ and $r$ so that the upper and lower potentials do not increase. Let us think of $\Phi^u(A)$ as a function of an $n^2$ dimensional vector (consisting of entries of $A$). Then in the first approximation $\Phi^{u+\delta U}(A + tY) \approx \Phi^{u+\delta U}(A) + tY \cdot U$, where $U$ is the gradient of $\Phi^{u+\delta U}$ at $A$ ($U$ is an $n \times n$ matrix).

Thus the potential function does not increase, $\Phi^{u+\delta U}(A + Y) \leq \Phi^{u}(A)$, roughly when $tY \cdot U \leq 1$. Similarly, $\Phi_{l+\delta L}(B + tY) \leq \Phi_{l}(B)$, roughly when $tY \cdot L \geq 1$, where $L$ is the gradient of $\Phi_{l+\delta L}$ at $B$. Following [3], we make these statements precise (we need to take into account lower order terms). We define matrices $U_A$ and $L_B$,

$$U_A = \frac{((u + \delta U)I - A)^{-2}}{\Phi^u(A) - \Phi^{u+\delta U}(A)} + ((u + \delta U)I - A)^{-1};$$

$$L_B = \frac{(P_S(B - (l + \delta L)I)P_S)^1}{\Phi^{l+\delta L}(B) - \Phi_{l}(B)} - (P_S(B - (l + \delta L)I)P_S)^1.$$

Lemma 3.10. (Upper Barrier Shift) Suppose $\lambda_{\text{max}}(A) < u$ and $Y = vv^T$ is a rank-one update. If $U_A \cdot Y \leq \frac{1}{t}$ then $\Phi^{u+\delta U}(A + tY) \leq \Phi^{u}(A)$ and $\lambda_{\text{max}}(A + tY) < u + \delta U$.

Proof. Let $u' = u + \delta U$ and $P = P_{L(A+tY)}$. By the Sherman–Morrison formula (Lemma (3.4)), we can write the updated potential as:

$$\Phi^{u+\delta U}(A + tY) = \text{tr} P(u' I - A - tY)^{-1}P = \text{tr} P \left( (u' I - A)^{-1} + \frac{t(u' I - A)^{-1}Y(u' I - A)^{-1}}{1 - t(u' I - A)^{-1}} \right) P$$

$$= \text{tr} P(u' I - A)^{-1}P + \frac{tP(u' I - A)^{-1}Y(u' I - A)^{-1}P}{1 - t(u' I - A)^{-1}} \cdot Y$$

$$\leq \Phi^{u+\delta U}(PAP) + \frac{t(u' I - A)^{-2} \cdot Y}{1 - t(u' I - A)^{-1}} \cdot Y$$

$$\leq \Phi^{u+\delta U}(A) + \frac{t(u' I - A)^{-2} \cdot Y}{1 - t(u' I - A)^{-1}} \cdot Y$$

$$= \Phi^u(A) - (\Phi^u(A) - \Phi^{u+\delta U}(A)) + \frac{(u' I - A)^{-2} \cdot Y}{1/t - (u' I - A)^{-1}} \cdot Y$$

Here, we used Corollary 3.7 for the inequality on line 4.

Substituting $U_A \cdot Y \leq 1/t$ gives $\Phi^{u+\delta U}(A + tY) \leq \Phi^u(A)$. The statement about $\lambda_{\text{max}}$ follows from continuity of eigenvalues. \hfill $\square$
Lemma 3.11. (Lower Barrier Shift) Suppose $\lambda_{\min}(B|_S) > l + \delta_L$ and $Y = vu^T$ is a rank-one update. If $L_B \cdot Y \geq 1/t$ then $\Phi_{l+\delta_L}(B + tY) \leq \Phi_l(B)$ and $\lambda_{\min}((B + tY)|_S) > l + \delta_L$.

Proof. We proceed as in the proof for the upper potential. Let $l' = l + \delta_L$ and $P = P_S$. By the Sherman–Morrison formula for the pseudoinverse (Lemma 3.5), we have:

$$\Phi_{l+\delta_L}(B + tY) = \text{tr}(P(B + tY - l'I)P) = \text{tr}(P(B - l'I)P + tPY P)$$

$$= \text{tr}(P(B - l'I)P) - \frac{t \text{tr}((P(B - l'I)P)Y(P(B - l'I)P)^\dagger)}{1 + t(P(B - l'I)P)^\dagger \cdot Y}$$

$$= \Phi_l(B) + (\Phi_{l+\delta_L}(B) - \Phi_l(B)) - \frac{t(P(B - l'I)P)^{12} \cdot Y}{1 + t(P(B - l'I)P)^\dagger \cdot Y}$$

Note that matrix $U_A$ is positive semidefinite. Rearranging shows that $\Phi_{l+\delta_L}(B + Y) \leq \Phi_l(B)$ when $L_A(\pi) \geq 1/t$. It is immediate that $\lambda_{\min}(P_S(A + t\pi\pi^T)P_S) > l + \delta_L$ since $\lambda_{\min}(P_SAP_S) > l + \delta_L$.

Now we prove that we can choose $Y_i$ and $t$ so that conditions of both lemmas are satisfied.

Lemma 3.12. (Both Barriers) If $\Phi^u(A) \leq \epsilon_U$ and $\Phi_l(B) \leq \epsilon_L$ and $\epsilon_U, \epsilon_L, \delta_U, \delta_L$ satisfy

$$0 \leq \frac{1}{\delta_U} + \epsilon_U + \max(N, T) \leq \frac{1}{\delta_L} - \epsilon_L,$$

and $X, Y_i, \text{cost}_i, Z, T$ and $N$ as in Theorem 3.3, $M^* - X$ is non-singular on $S$, then there exists $i$ and positive $t$ for which

$$L_B \cdot (ZY_iZ) \geq 1/t \geq U_A \cdot Y_i, \text{ and}$$

$$\text{cost}_i \cdot t \leq 1/\max(N, T).$$

We will use the following lemma

Lemma 3.13. $\sum_{i=1}^m U_A \cdot Y_i \leq \frac{1}{\delta_U} + \epsilon_U$ and $\sum_{i=1}^m L_B \cdot (ZY_iZ) \geq \frac{1}{\delta_L} - \epsilon_L$.

Proof. 1. We use Corollary 3.9 to bound the Frobenius product of $Y_i$ with each of the two summands in the definition of $U_A$ (note that they are positive semidefinite), we get

$$\sum_{i=1}^m U_A \cdot Y_i = U_A \cdot \sum_{i=1}^m Y_i = U_A \cdot (M^* - X)$$

$$= \frac{((u + \delta_U)I - A)^{-2}}{\Phi^u(A) - \Phi^{u+\delta_U}(A)} \cdot (M^* - X) + \left(\frac{((u + \delta_U)I - A)^{-2}}{\Phi^u(A) - \Phi^{u+\delta_U}(A)} \cdot (M^* - X)\right)$$

$$\leq \sum_{i=n-T+1}^n \lambda_i \left(\left(\frac{((u + \delta_U)I - A)^{-2}}{\Phi^u(A) - \Phi^{u+\delta_U}(A)}\right) \cdot (M^* - X)\right) + \sum_{i=n-T+1}^n \lambda_i \left(\left(\frac{((u + \delta_U)I - A)^{-2}}{\Phi^u(A) - \Phi^{u+\delta_U}(A)}\right) \cdot (M^* - X)\right)$$

$$= \sum_{i=n-T+1}^n \frac{1}{\Phi^u(A) - \Phi^{u+\delta_U}(A)} \cdot (u + \delta_U - \lambda_i(A))$$

9
Note that the first term is at most 1/\(\delta_u\), since
\[
\sum_{i=n-T+1}^{n} \frac{1}{(u+\delta_u - \lambda_i(A))^2} \leq \sum_{i=n-T+1}^{n} \frac{1}{(u-\lambda_i(A))(u+\delta_u - \lambda_i(A))} = \frac{1}{\delta_u} \sum_{i=n-T+1}^{n} \left( \frac{1}{u-\lambda_i(A)} - \frac{1}{(u+\delta_u - \lambda_i(A))} \right) = \frac{\Phi^u(A) - \Phi^{u+\delta_u}(A)}{\delta_u}
\]
and the second term equals \(\Phi^{u+\delta_u}(A)\). Thus \(\sum_{i=1}^{n} U_A \cdot Y_i \leq \epsilon_u + 1/\delta_u\).

2. Let \(P\) be the projection on \(\text{Im}(M^* - X)\). Since \((M^* - X)\) is non-singular on \(S\), \(PP_S = P_S\). We have,
\[
\sum_{i=1}^{m} L_B \cdot ZY_i Z = L_B \sum_{i=1}^{m} ZY_i Z = L_B \cdot Z(M^* - X)Z = L_B \cdot P
\]
\[
= \text{tr} \left( \frac{(P_S(B - (l + \delta_l)I)P_S)^{\dagger 2}}{\Phi^{l+\delta_l}(B) - \Phi^l(B)} - (P_S(B - (l + \delta_l)I)P_S)^{\dagger} \right)
\]
\[
= \sum_{i=1}^{m} \left( \frac{1}{\Phi^{l+\delta_l}(B) - \Phi^l(B)} - \sum_{i=1}^{m} \frac{1}{\lambda_i(B|_S) - (l + \delta_l)} \right)
\]
\[
\geq 1/\delta_l - \epsilon_L,
\]
where the last line follows from Claim 3.6 in [3].

\[
\]

**Proof.** (Of Lemma 3.12) For the previous lemma, we get: \(\sum_{i=1}^{m} (U_A \cdot Y_i + \max(N,T)cost_i) \leq \frac{1}{\delta_u} + \epsilon_u + \max(N,T) \leq L_B \cdot (ZY_i Z)\). Thus for some \(i\), \(U_A \cdot Y_i + \max(N,T)cost_i \leq L_B \cdot (ZY_i Z)\). Letting \(t = (L_B \cdot (ZY_i Z))^{-1}\), we satisfy (4) and (5).

3.3 Proof of Theorem 3.3

Now we are ready to prove Theorem 3.3. We assume that \(M^* - X\) is non-singular on \(S\) (which we can ensure by an arbitrary small perturbation).

We start with \(A^{(0)} = X, B^{(0)} = 0\) and all weights \(w_i^{(0)} = 0\). We define parameters as follows,
\[
\delta_L = 1/(2\max(N,T)), \quad \epsilon_L = 1/(4\delta_L), \quad l_0 = -4k\delta_L, \quad u_0 = 4T\delta_L + 1,
\]
so as to satisfy conditions of Lemma 3.12, \(\Phi^{u}(A^{(0)}) = \Phi^{u}(X) = \sum_{i=1}^{T} \frac{1}{u_0 - \lambda_{\max} - i(N)} \leq T/(u_0 - 1) = \epsilon_u, \Phi^l(B^{(0)}) = \sum_{i=1}^{T} \frac{1}{u_0 - \lambda_L - i(N)} \leq T/(u_0 - 1) = \epsilon_u, \Phi^l(B^{(0)}) = \sum_{i=1}^{T} \frac{1}{u_0 - \lambda_L - i(N)} \leq T/(u_0 - 1) = \epsilon_u, \Phi^l(B^{(0)}) = \sum_{i=1}^{T} \frac{1}{u_0 - \lambda_L - i(N)} \leq T/(u_0 - 1) = \epsilon_u, \Phi^l(B^{(0)}) = \sum_{i=1}^{T} \frac{1}{u_0 - \lambda_L - i(N)} \leq T/(u_0 - 1) = \epsilon_u\).

Then we iteratively apply Lemma 3.12. At iteration \(q\), we find an index \(i\) and a positive \(t\) such that \(L_{B^{(q)}(ZY_i Z)} \geq 1/t \geq U_{A^{(q)}(Y_i)}, cost_i \cdot t \leq 1/\max(N,T)\), and increment the weight of matrix \(Y_i\) by \(t\): \(w_i^{(q+1)} = w_i^{(q)} + t\); update \(l = l + \delta_L\) and \(u = u + \delta_u\). The total cost increases by at most \(1/\max(N,T)\). Finally, after \(N\) iterations we obtain matrices \(A^{(N)}\) and \(B^{(N)}\) with
\[
\lambda_{\max}(A^{(N)}) \leq u_0 + N\delta_U = 2(N + T)/\max(N,T) + 1 \equiv \theta_{\max},
\]
\[
\lambda_{\min}(B^{(N)}|_S) \geq l_0 + N\delta_L = (N/2 - 2k)/\max(N,T) \equiv \theta_{\min}.
\]
Now consider an arbitrary unit vector $v$. Let $v = v_S + v_{S\perp}$, where $v_S \in S$ and $v_{S\perp} \perp S$. Since $B^{(N)} \succeq \theta_{\min} P_S$ and $v_S \in S$,

$$v_{S}^{T} A^{(N)} v_{S} = v_{S}^{T} (X + (P_S (M^* - X) P_S)^{1/2} B^{(N)} (P_S (M^* - X) P_S)^{1/2}) v_{S}$$

$$\geq v_{S}^{T} (X + (P_S (M^* - X) P_S)^{1/2} \theta_{\min} P_S (P_S (M^* - X) P_S)^{1/2}) v_{S}$$

$$= \theta_{\min} v_{S}^{T} M^* v_{S} + (1 - \theta_{\min}) v_{S}^{T} X v_{S} \geq \theta_{\min} \lambda_{\min}(M^*) \|v_S\|^2.$$  

On the other hand, $v_{S\perp}^{T} A^{(N)} v_{S\perp} \leq \theta_{\max} \|v_{S\perp}\|$. Thus from the triangle inequality for the norm induced by $A^{(N)}$, we get

$$(v^{T} A^{(N)} v)^{1/2} \geq \theta_{\min} \lambda_{\min}(M)^{1/2} \|v_S\| - \theta_{\max} \|v_{S\perp}\| \geq \theta_{\min} \lambda_{\min}(M)^{1/2} - (\theta_{\max} + \theta_{\min} \lambda_{\min}(M)^{1/2}) \|v_{S\perp}\|.$$  

On the other hand, since $S$ is an eigenspace of $X$ corresponding to $k$ smallest eigenvalues,

$$(v^{T} A^{(N)} v)^{1/2} \geq (v^{T} X v)^{1/2} \geq (v_{S\perp}^{T} X v_{S\perp})^{1/2} \geq \lambda^{*1/2} \|v_{S\perp}\|.$$  

One of the two bounds above for $(v^{T} A^{(N)} v)^{1/2}$ increases and the other decreases as $\|v_{S\perp}\|$ increases. They are equal when $\|v_{S\perp}\| = \theta_{\min} \lambda_{\min}(M^*)^{1/2} \lambda_{\min}^{1/2} + \theta_{\max}^{1/2} \lambda_{\min}(M^{*})^{1/2}$. Therefore, $(v^{T} A^{(N)} v)^{1/2} \geq \theta_{\min}^{1/2} \lambda_{\min}(M^{*})^{1/2} \lambda_{\min}^{1/2} + \theta_{\max}^{1/2} \lambda_{\min}(M^{*})^{1/2}$. We conclude that

$$\lambda_{\min}(A^{(N)}) = \min_{v: \|v\| = 1} v^{T} A^{(N)} v \geq \frac{\theta_{\min} \lambda^* \lambda_{\min}(M^*)}{(\lambda^{*1/2} + \theta_{\max}^{1/2} + \theta_{\min}^{1/2} \lambda_{\min}(M^{*})^{1/2})^{2}}.$$  

Plugging in the values of parameters, we get the statement of the theorem for $M = A^{(N)}$. The total cost is at most $N/ \max(N, T) = \min(1, N/T)$.

Finally, we prove Claim 3.2.

**Claim 3.2.** Let $V = \text{Im}(L_{G+W}) = \ker(L_{G+W})^\perp$. Let $L_e$ be the Laplacian of the edge $e$. Define

$$X = \left(L_{G+W}^{1/2} L_{G}(L_{G+W}^{1/2})^{1/2}\right)|_V,$$

$$Y_e = w_e \left(L_{G+W}^{1/2} L_e(L_{G+W}^{1/2})^{1/2}\right)|_V,$$

$$\text{cost}_e = w_e / \left(\sum_{d \in E_W} w_d\right).$$

Since $L_G + \sum_{e \in E_W} w_e L_e = L_{G+W}$, we have $X + \sum_{e \in E_W} Y_e = I$. By the definition of the $(k, T, \lambda^*)$-patch, $\text{tr}(I - X) \leq T$ and $\lambda^* \leq \lambda^{k+1}(X)$. We apply Theorem 3.3 to matrices $X$, $Y_e$ and $M^* = I$. We obtain a set of weights $\rho_e$ — supported on at most $N$ edges — such that

$$c_1 \min(N/T, 1) \cdot \lambda^* \leq \min\left(X + \sum_{e \in E_W} \rho_e Y_e\right) \leq \max\left(X + \sum_{e \in E_W} \rho_e Y_e\right) \leq c_2.$$  

Let $\tilde{w}_e = \rho_e w_e$. Weights $\tilde{w}_i$ define subgraph $W_k$ with at most $N$ edges. It follows that

$$c_1 \min(N/T, 1) \lambda^* L_{G+W} \preceq L_{G+W_k} \preceq c_2 L_{G+W}.$$  

The total weight of edges of $W_k$ is $\sum_{e \in E_W} \rho_e w_e = (\sum_{e \in E_W} \rho_e \text{cost}_e) \sum_{d \in E_W} w_d \leq \min(1, N/T) \sum_{d \in E_W} w_d$. \qed
4 Constructing Nearly-Optimal Ultrasparsifiers

We now apply our subgraph sparsification to build ultrasparsifiers. Recall that a weighted graph $U$ is a $(\kappa, k)$-ultrasparsifier of another graph $G$ if $U \preceq G \preceq \kappa \cdot U$ and $U$ has only $n - 1 + k$ edges, where $n$ is the number of vertices in $U$ and $G$. The main result of this section is the following theorem.

**Theorem 4.1.** For any integer $k > 0$, every graph has an $(\frac{\kappa}{k} \log n \tilde{O}(\log \log n), k)$-ultrasparsifier.

Our basic idea to build a good ultrasparsifier $U$ is quite simple. Without loss of generality, we can assume that $G$ is connected and has $O(n)$ edges. Otherwise given a graph $G$, we can first find a linear size sparsifier using $[3]$, for each of its connected components, and build a good ultrasparsifier for each component. Because $U$ is only $k$ edges aways from a tree, our construction starts with good tree $T$. As it will be much more clear below, the quality of a tree is measured by its stretch, as introduced by Alon, Karp, Peleg and West $[2]$.

Suppose $T$ is a spanning tree of $G = (V, E, w)$. For any edge $e \in E$, let $e_1, \ldots, e_k \in F$ be the edges on the unique path in $T$ connecting the endpoints of $e$. The stretch of $e$ w.r.t. $T$ is given by $st_T(e) = w(e)(\sum_{i=1}^{k} \frac{1}{w(e_i)})$. The stretch of the graph $G$ with respect to $T$ is defined by $st_T(G) = \sum_{e \in E} st_T(e)$. Our construction will start with a spanning tree with the lowest possible stretch. By $[1]$, we can in polynomial time grow a spanning tree $T$ with

$$st_T(G) = O(n \log n \log \log n (\log \log \log n)^3).$$

**Remark 4.2.** For the sake of simplicity of the presentation, we will show the construction of ultrasparsifiers with $\Theta(k)$ edges. We note that by choosing the appropriate constants, the number of edges can be made exactly $k$.

Let $\kappa = c_1 \cdot st_T(G)/k$ for a sufficiently large constant $c_1$. Our job is to choose $\Theta(k)$ more weighted edges $\tilde{W}$ and set $U = T + \tilde{W}$ such that $c_2 \cdot U \preceq G \preceq \kappa \cdot U$, for a constant $c_2$. To this end, let $W = (1/(c_3 \kappa)) \cdot G$, for some constant $c_3$. Then, $G = c_3 \kappa \cdot W \preceq c_3 \kappa \cdot (W + T)$. Also, because $T \preceq G$, we have $T + W \preceq (1 + 1/(c_3 \kappa))G \preceq c_4 \cdot G$, for a constant $c_4$. Therefore, if we can find a $\Theta(k)$-edge subgraph $\tilde{W}$ of $T + \tilde{W} \preceq \Theta(1) \cdot (T + W)$, we can then build a $n - 1 + \Theta(k)$ edge graph $U = T + \tilde{W}$ satisfying $c_2 \cdot U \preceq G \preceq \kappa \cdot U$ (if we choose our constants $c_i$'s carefully).

To apply our subgraph sparsification results to construct $\tilde{W}$, we use the following structure result of Spielman and Woo ([21]: Theorem 2.1 and Corollary 2.2).

**Lemma 4.3.** (Theorem 2.1 in [21]) (1) $Tr(L_T^{-1/2} L_G L_T^{-1/2}) = st_T(G)$. (2) For every $t > 0$, the number of eigenvalues of $L_T^{-1/2} L_G L_T^{-1/2}$ greater than $t$ is at most $st_T(G)/t$.

We now use Lemma 4.3 to prove the following lemma, from which Theorem 4.1 follows directly.

**Lemma 4.4.** $W$ is a $(k, O(k), \Theta(1))$-patch for $T$.

**Proof.** Let $\lambda_i = \lambda_i((L_{T+W}^\dagger)^{1/2} L_T (L_{T+W}^\dagger)^{1/2})$ be the $i$-th eigenvalue, and $y_i$ be the corresponding eigenvector. Let $x_i = L_{T+W}^{1/2} y_i$. Then,

$$\lambda_i = \lambda_i((L_{T+W}^\dagger)^{1/2} L_T (L_{T+W}^\dagger)^{1/2}) = \frac{x_i^T L_T x_i}{x_i^T L_{T+W} x_i} = \frac{x_i^T L_{T+W} x_i}{x_i^T L_T x_i + x_i^T L_G x_i/(c_3 \kappa)},$$
implying
\[ \frac{x_i^T L_G x_i}{x_i^T L_T x_i} = \frac{1 - \lambda_i}{\lambda_i} c_3 \kappa = \left( \frac{1 - \lambda_i}{\lambda_i} \right) c_3 \frac{\text{st}_T(G)}{k} = \frac{\text{st}_T(G)}{k} \]

It follows from the definition of \( \lambda_i \) that \( 0 \leq \lambda_i < 1 \). Hence, \( (1 - \lambda_{i-1})/\lambda_{i-1} \geq (1 - \lambda_i)/\lambda_i \). By Courant–Fischer theorem and the property 2 of Lemma 4.3, we have \( \lambda_{k+1} \geq 0 \). Therefore, \( \lambda_{k+1} \geq \frac{c_1 c_3}{1 + c_1 c_3} = \Theta(1) \). We also have,

\[
\text{tr} \left( (L_{T+W}^t)^{1/2} L_W (L_{T+W}^t)^{1/2} \right) \leq \text{tr} \left( (L_T^t)^{1/2} L_W (L_T^t)^{1/2} \right) = \frac{1}{c_3} \kappa \text{st}_T(G) = \frac{k}{c_3} = \Theta(k).
\]

We proved that \( W \) is a \( (k, O(k), \Theta(1)) \)-patch for \( T \).

We next show that the parameters of the ultrasparsifiers we obtained are optimal, up to low order terms.

**Theorem 4.5.** Let \( G \) be a Ramanujan \( d \)-regular expander graph, for some constant \( d \). Let \( U \) a \( (\kappa, N) \) ultrasparsifier for \( G \). Then \( \kappa \geq \frac{n \log n}{N} \).

**Proof.** Let \( T \) be a low-stretch spanning tree of \( G \), as above. As mentioned in [1], \( \text{st}_T(G) = \Omega(m \log n) \) where \( m \) is the number of edges of the original graph. From lemma 4.3, and the conditions on the stretch of \( T \) we have \( \text{Tr}(L_G L_T^t) = \text{st}_T(G) \geq C \cdot n \log n \) for some constant \( C \).

Since \( x^T L_T x = \Theta(1) \) for the expander, the above inequality implies that \( \sum_{i=1}^n \frac{1}{x_i^T L_T x_i} \geq n \log n \) where \( x_i \) are the eigenvectors of \( L_G(L_T^t) \). It is immediate from Markov’s inequality that there exists some \( k \) such that \( x_k^T L_T x_k \leq \frac{C}{n \log n} \). Assume that for all \( i \leq k \) we have \( x_i^T L_T x_i \leq x_k^T L_T x_k \leq \frac{C k}{n \log n} \). (Otherwise take \( k' < k \) appropriately). Then also \( \lambda_k(L_T) \leq \frac{C k}{n \log n} \). By the minmax theorem for eigenvalues this implies that adding \( N = k - 2 \) edges to \( T \) will result to a graph \( U \) with \( \lambda_2(L_U) \leq \lambda_k(L_T) \leq \frac{C k}{n \log n} \). Thus any ultrasparsifier \( U \) with \( N \) edges will have

\[
C_2 = \lambda_2(L_G) \leq \kappa \lambda_2(L_U) \leq \frac{C_1 k}{n \log n} \Rightarrow \kappa \geq \Omega\left( \frac{n \log n}{k} \right) = \Omega\left( \frac{n \log n}{N} \right)
\]

\[ \square \]

### 5 Maximizing Algebraic Connectivity by Adding few edges

In this section, we present an approximation algorithm for the following problem: given a graph \( G = (V, E_{\text{base}}) \), a set of candidate edges \( E_{\text{cand}} \), and a parameter \( k \), add at most \( k \) candidate edges to \( G \) so as to maximize its algebraic connectivity, that is, find a subset \( E \subset E_{\text{cand}} \) that maximizes \( \lambda_2(L_{G+E}) \). The problem was introduced by Ghosh and Boyd [5], who presented a heuristic for it. It is known that the problem is NP-hard [15]. But prior to this work, no approximation algorithm was known for it.

We use two upper bounds for the cost of the combinatorial solution in order to prove an approximation guarantee: one upper bound is the SDP value, \( \lambda_{SDP} \), and the other is \( \lambda_{k+2}(L_G) \).
(see Lemma 5.1). Note that neither of these two bounds are good approximations for the value of the optimum solution by themselves (for instance, if $G$ consists of $n$ isolated vertices, $(V, E_{\text{cand}})$ is an expander, $k < n$, then the value of the combinatorial solution is 0 but $\lambda_{\text{SDP}} \sim k/n$), but their combinations lead to a good upper bound for the optimum solution $\lambda_{\text{OPT}}$.

For clarity and simplicity of exposition, we assume here that $(V, E_{\text{base}})$ and $(V, E_{\text{cand}})$ are bounded degree graphs with the maximum degree $\Delta$. Our algorithm uses a natural semidefinite relaxation that was also used by Ghosh and Boyd [5]. We introduce a variable $w_e$ (the weight of the edge $e \in E_{\text{cand}}$) and add constraints that all edge weights are between 0 and 1, and the total weight is at most $k$. Then we require that $\lambda_2(L_G + \sum e w_e L_e) \geq \lambda_{\text{SDP}}$ (where $L_e$ is the Laplacian of the edge $e$). We do that by adding an SDP constraint $L_G + \sum e w_e L_e \succeq \lambda_{\text{SDP}} P_{\{1,\ldots,1\}}$, where $P_{\{1,\ldots,1\}}$ is the projection on the space orthogonal to $(1,\ldots,1)$. We get the following SDP relaxation.

\begin{align*}
\text{maximize:} & \quad \lambda_{\text{SDP}}, \\
\text{subject to:} & \quad L_G + \sum_{e \in E_{\text{cand}}} w_e L_e \succeq \lambda_{\text{SDP}} P_{\{1,\ldots,1\}}, \\
& \quad \sum_{e \in E_{\text{cand}}} w_e \leq k, \\
& \quad 0 \leq w_e \leq 1 \text{ for every } e \in E_{\text{cand}}.
\end{align*}

We solve the semidefinite program and obtain solution $\{w_e\}_{e \in E_{\text{cand}}}$. The total weight of all edges is $k$, however, the number of edges involved, or the support of the solution could be significantly higher than $k$.

We use our algorithm to sparsify the SDP solution using Theorem 3.3. More precisely, we apply Theorem 3.3 with $X = L_G/(4\Delta)$ and $Y_e = w_i L_e/(4\Delta)$ restricted to the space $(1,\ldots,1)$, $N = 8k$, $T = \text{tr}(\sum e w_e L_e)/(4\Delta) \leq k$ and $\text{cost}_i = w_i$ (we divide $L_G$ and $L_e$ by $4\Delta$ to ensure that $\lambda_{\max}(X + \sum Y_i) \leq 1$). We get a set of weights $\rho_e$ supported on at most $8k$ edges s.t.

$$\frac{1}{4\Delta} \lambda_2(L_G + \sum e \rho_e w_e L_e) = \lambda_{\min}(X + \sum e \rho_e Y_e) \geq c\lambda_{k+2}(X)\lambda_{\min}(X + \sum Y_e) \geq c\frac{1}{(4\Delta)^2} \lambda_{k+2}(L_G)\lambda_{\text{SDP}}.$$ 

That is, we obtain a combinatorial weighted solution $\tilde{w}_e = \rho_e w_e$ whose value is at least $c\lambda_{k+2}(L_G)\lambda_{\text{SDP}}/(4\Delta)$ (if $k + 2 > n$, the value is at least $c\lambda_{\text{SDP}}$). We next show that $\lambda_{\text{SDP}} \geq \lambda_{\text{OPT}}$ and $\lambda_{k+2}(G) \geq \lambda_{\text{OPT}}$. Therefore, the value of the solution is at least $c\lambda_{k+2}(L_G)/\Delta$.

**Lemma 5.1.** The value of the optimal solution, $\lambda_{\text{OPT}}$, is at most $\lambda_{k+2}(L_G)$.

**Proof.** Consider the optimal solution $E$. Let $L_E$ be the Laplacian of the graph formed by $E$. Note that $\text{rank}(L_E) \leq |E| \leq k$, therefore, $\dim \ker L_E \geq n - k$. Let $S$ be the $k + 1$-dimensional space spanned by the eigenvectors of $L_G$ corresponding to $\lambda_2(L_G), \ldots, \lambda_{k+2}(L_G)$. Since $\dim S + \dim \ker E > n$, spaces $S$ and $\ker L_E$ have a non-trivial intersection. Choose a unit vector $v \in \ker S \cap L_E$. We have $v(L_G + L_E) v^T \leq \lambda_{k+2}(L_G) + 0 = \lambda_{k+2}(L_G)$. Also $v$ is orthogonal to the vector $(1,\ldots,1)$. Therefore, $\lambda_{\text{OPT}} = \lambda_2(L_G + L_E) \leq \lambda_{k+2}(L_G)$. \hfill \square

The edges in the support of $\tilde{w}_e$, $E = \{\tilde{w}_e : \tilde{w}_e \neq 0\}$, form a non-weighted combinatorial solution. Since $\lambda_{\max}(L_X + \sum e \tilde{w}_e L_e) = O(\Delta)$, all weights $\tilde{w}_e$ are bounded by $O(\Delta)$, and thus the algebraic connectivity of $G + E$ is at least $c\lambda_{k+2}(L_G)\lambda_{\text{SDP}}/\Delta^2$.  

---

14
Theorem 5.2. There is a polynomial time approximation algorithm that finds a solution of value at least $c\lambda_{OPT}^2/\Delta$ supported on at most $8k$ edges with total weight at most $k$. If $k \geq n$ the algorithm finds a constant factor approximation.

We present two corollaries for special instances of the problem.

Corollary 5.3. If it is possible to make $G$ an expander by adding $k$ edges (and thus $\lambda_{OPT} \sim \Delta$), then the algorithm finds a constant factor approximation.

Note that if the graph formed by candidate edges is an expander then the value of the following SDP solution $w_e = k/|E_{cand}|$ for each edge $e \in E_{cand}$ is $\Omega(k/n)$, thus $\lambda_{SDP} \geq ck/n$.

Corollary 5.4. If the graph formed by candidate edges is an expander, then the approximation algorithm from Theorem 5.2 finds a solution of value at least $c\lambda_{OPT}^2/\Delta$.

Remark 5.5. It is possible to get rid of the dependence on $\Delta$ in Theorem 5.2 and Corollary 5.4 and obtain approximation guarantees of $c \min(\lambda_{OPT}, \lambda_{OPT}^2)$ and $ck/n \lambda_{OPT}$ respectively. We omit the details in this extended abstract.
