Abstract—This paper investigates the problem of regulating, at every time, a linear dynamical system to the solution trajectory of a time-varying constrained convex optimization problem. The proposed feedback controller is based on an adaptation of the saddle-flow dynamics, modified to take into account projections on constraint sets and output-feedback from the plant. We derive sufficient conditions on the tunable parameters of the controller (inherently related to the time-scale separation between plant and controller dynamics) to guarantee exponential input-to-state stability of the closed-loop system. The analysis is tailored to the case of time-varying strongly convex cost functions and polytopic output constraints. The theoretical results are further validated in a ramp metering control problem in a network of traffic highways.

I. INTRODUCTION

This paper investigates the problem of online optimization of linear time-invariant (LTI) systems. The objective is to design an output feedback controller to steer the inputs and outputs of the system towards the solution trajectory of a time-varying optimization problem (see Fig. 1). Such problems correspond to scenarios where cost and constraints may change over time to reflect dynamic performance objectives or simply to take into account time-varying unknown disturbances entering the system. This setting emerges in many engineering applications, including power systems [1], transportation networks [3], [4], and communication systems [5].

The design of feedback controllers inspired from optimization algorithms has received significant attention during the last decade [1], [2], [6]–[13]. While most of the existing works focus on the design of optimization-based controllers for static problems [2], [6]–[9], [11], [12], or consider unconstrained time-varying problems [10], [13], an open research question is whether controllers can be synthesized to track solutions trajectories of time-varying problems with input and output constraints. Towards this direction, in this paper we consider optimization problems with a time-varying strongly convex cost, time-varying linear constraints on the output, and convex constraints on the input. We leverage online saddle-point dynamics for controller synthesis, and we establish the input-to-state stability [14] property for the system resulting from interconnecting the controller with the dynamical system. In particular, we leverage tools from singular perturbation theory [15] to provide sufficient conditions on the tunable controller parameters to guarantee tracking of the optimal solution trajectory. We remark that, while [16]–[20] show that primal-dual dynamics for have an exponential rate of convergence, the main challenges here are to derive exponential stability results for problems that are time-varying and where primal-dual dynamics are interconnected with a dynamical system subject to unknown disturbances (as in Fig. 1).

Related work. In the case of static plants (i.e., where the dynamics of the system are infinitely fast), controllers conceptually-inspired from continuous-time saddle-point dynamics (or flows) are studied in [6] for optimization problems with time-invariant costs and constraints on the system outputs, whereas more general saddle-point flows are studied in [7], [12], [21], and [22, Sec. 3]. While the above works focus on optimization problems with static plants, the authors in [2], [8], [9], [11] prove that gradient-flow dynamics can be used as feedback controllers for dynamical systems in the case of unconstrained optimization problems with time-invariant costs. The work [11] also extends these results to the case of constraints on the system inputs by using projected gradient flows. Constraints on the system outputs are considered in [1], together with a controller inspired from primal-dual dynamics based on the Moreau envelope. For time-varying unconstrained optimization problems, prediction-correction algorithms are used in [10]. Exponential rates of convergence were proved for the first time in [13] for dynamic controllers based on gradient flows and accelerated hybrid dynamics.

In terms of classes of plants, stable LTI systems are considered in [1], [2], [13], stable nonlinear systems in [11], input-linearizable systems in [10], and input-affine nonlinear system in [7]. Finally, [23], [24] consider online implementations of optimization problems arising in model predictive control.
Contributions. This work features three main contributions. C1) We design an output feedback controller, inspired from primal-dual dynamics, to regulate a dynamical system to the solution trajectory of a time-varying constrained optimization problem without requiring information or measurements of the external disturbances entering the state equation. For problems with equality constraints, the controller is designed based on the classical Lagrangian function. Instead, for problems with inequality constraints, we employ a regularized Lagrangian [25] to guarantee exponential convergence to an approximate KKT trajectory. C2) We consider constraints on the system input and we propose a novel projected primal-dual feedback controller that guarantees constraint satisfaction. Differently from using the classical projection on the tangent cone, the proposed controller yields trajectories that are continuously differentiable, which allows us to simplify the analysis and to establish strong robustness guarantees. As a minor contribution, we demonstrate that the proposed framework is applicable to more-general LTI systems, including switched systems with common quadratic Lyapunov functions. C3) We apply the proposed controllers to solve a ramp metering problem in traffic systems. We compare our results with state-of-the-art controllers, including ALINEA [26] and model predictive control, illustrating the advantages of our method.

We emphasize that, relative to [1]: (i) our sufficient conditions for convergence are easier to check as they do not require to numerically solve a linear matrix inequality, and (ii) our framework does not require to compute the Moreau envelope. Relative to [6], [7], [11], [12], we account for time variability in the cost functions and in the disturbances, and we prove exponential convergence. Relative to [20], [27], we investigate the regularity assumptions on the temporal evolution of (3). We introduce the following regularity assumptions on the temporal evolution of (3).

**Assumption 1:** The matrix $A$ is Hurwitz stable, namely, for any $Q_x \in \mathbb{R}^{n \times n}, Q_x > 0$, there exists $P_x \in \mathbb{R}^{n \times n}, P > 0$, such that $A^T P_x + P_x A = -Q_x$.

Under Assumption 1 for fixed vectors $u_{eq} \in \mathbb{R}^m$, $w_{eq} \in \mathbb{R}^q$, (3) has a unique stable equilibrium point $x_{eq} = -A^{-1}(B u_{eq} + E w_{eq})$. Moreover, at equilibrium, the relationship between system inputs and outputs is given by the algebraic relationship:

$$y_{eq} = -CA^{-1}B u_{eq} + (D - CA^{-1}E) w_{eq}.$$ (2)

Given any time-varying and unknown exogenous input $u_t$ to (3), we focus on the problem of regulating the plant to the solutions of the following time-varying optimization problem:

$$(u_t^*, y_t^*) \in \arg \min_{u \in U, y \in \mathbb{R}^p} \phi_t(u) + \psi_t(y) \tag{3a}$$

s.t. $\quad y = Gu + H w_t$, $K_t y \leq e_t$,

for all $t \in \mathbb{R}_{\geq 0}$, $\phi_t : \mathbb{R}^m \rightarrow \mathbb{R}$, $\psi_t : \mathbb{R}^p \rightarrow \mathbb{R}$. Moreover, the maps $t \mapsto K_t \in \mathbb{R}^{r \times p}$ and $t \mapsto e_t \in \mathbb{R}^r$ describe a time-varying output constraint, while $U \subseteq \mathbb{R}^m$ denotes a closed and convex set describing constraints on the input. Problem (3) formalizes a regulation problem, where the objective is to select an optimal input-output pair $(u_t^*, y_t^*)$ that minimizes the cost specified by the loss functions $\phi_t$ and $\psi_t$. We note that, because cost functions and constraints are time-varying, the solutions of (3) are also time-varying, and thus they characterize optimal trajectories. We impose the following regularity assumptions on the temporal evolution of (3).

**Assumption 2:** The following properties hold.

(a) The functions $u \mapsto \phi_t(u)$ and $y \mapsto \psi_t(y)$ are continuously differentiable, uniformly in $t \in \mathbb{R}_{\geq 0}$.

(b) The function $u \mapsto \phi_t(u)$ is $\mu_u$-strongly convex, uniformly in $t \in \mathbb{R}_{\geq 0}$.

(c) There exist $\ell_u, \ell_y > 0$ such that for every $u, u' \in \mathbb{R}^m$ and $y, y' \in \mathbb{R}^p$, $\|\nabla \phi_t(u) - \nabla \phi_t(u')\| \leq \ell_u ||u - u'||$, $\|\nabla \psi_t(y) - \nabla \psi_t(y')\| \leq \ell_y ||y - y'||$, uniformly in $t \in \mathbb{R}_{\geq 0}$.

(d) For all $u \in \mathbb{R}^m$, $y \in \mathbb{R}^p$, $t \mapsto \nabla \phi_t(u)$ and $t \mapsto \nabla \psi_t(y)$ are locally Lipschitz.

**Assumption 3:** Problem (3) is feasible, and Slater’s condition [25, Assumption 1] holds for each $t \in \mathbb{R}_{\geq 0}$.

**Assumption 4:** The following regularity properties hold.

(a) The functions $u \mapsto \phi_t(u)$ is $\mu_u$-strongly convex, uniformly in $t \in \mathbb{R}_{\geq 0}$.

(b) The functions $t \mapsto \psi_t(y)$ are continuously differentiable, uniformly in $t \in \mathbb{R}_{\geq 0}$.

(c) The functions $t \mapsto \psi_t(y)$ are continuously differentiable, uniformly in $t \in \mathbb{R}_{\geq 0}$.

Under Assumptions 2, 3, the minimizer $(u_t^*, y_t^*)$ of (3) is unique for every $t \in \mathbb{R}_{\geq 0}$ [25, Page 2], while Assumption 4 guarantees that inputs and constraints of (3) vary continuously in time. The problem focus of this work is formalized next.

**Problem 1:** Design a dynamic output-feedback controller for (3) such that the inputs and outputs of (3) converge exponentially to the time-varying optimizer of (3), up to an asymptotic error that accounts for the temporal variability of both the optimizer and of the unknown disturbance.
III. CLOSED-LOOP PROJECTED SADDLE-POINT FLOWS

In this section, we present our controller synthesis method and we establish explicit convergence error bounds.

A. Controller Synthesis

For controller synthesis, we employ a regularized Lagrangian function and use a controller structure that relies on a modification of the saddle-point flow dynamics [6]. Consider the following Lagrangian function for (1):

\[
L_t(u, \lambda) := \phi_t(u) + \psi_t(Gu + Hw_t) + \lambda^T(K_t(Gu + Hw_t) - e_t),
\]

where \(\lambda \in \mathbb{R}^n_p\) denotes the vector of dual variables. We define the regularized Lagrangian function as follows:

\[
\tilde{L}_{\nu,t}(u, \lambda) := L_t(u, \lambda) - \frac{\nu}{2} \|\lambda\|^2,
\]

where \(\nu \in \mathbb{R}_{>0}\). The regularization term \(-\frac{\nu}{2} \|\lambda\|^2\) has the effect of making the function \(\tilde{L}_{\nu,t}(u, \lambda)\) strongly concave in \(\lambda\), for any \(u \in \mathbb{R}^m\) (see [25]). As a result, the regularization term induces a saddle-point map that is strongly monotone, uniformly in time [25]. On the other hand, the use of a regularization term comes at the cost of perturbing the saddle points. To this aim, we let

\[
z^*_{\nu,t} := (u^*_{\nu,t}, \lambda^*_{\nu,t}),
\]

denote any saddle-point of \(L_t(u, \lambda)\) and the saddle point of \(\tilde{L}_{\nu,t}(u, \lambda)\), respectively. We quantify the error due to regularization in the following result (adapted from [25, Prop. 3.1]).

**Lemma 3.1:** Let Assumptions 2-4 hold. For each \(t \in \mathbb{R}_{\geq 0}\), the following bound holds:

\[
\mu_u \|u^*_{\nu,t} - u^*_t\|^2 + \frac{\nu}{2} \|\lambda^*_t\|^2 \leq \frac{\nu}{2} \|\lambda^*_t\|^2,
\]

where \((u^*_t, \lambda^*_t)\) and \((u^*_{\nu,t}, \lambda^*_{\nu,t})\) are as in (5). In particular, inequality (6) implies that \(\|u^*_{\nu,t} - u^*_t\| \leq \sqrt{\frac{\nu}{2\mu_u}} \|\lambda^*_t\|\).

Remark 1: Lemma 3.1 shows that the error induced by the regularization term is bounded by the norm of the optimal multipliers of the non-regularized problem. Consequently, when the optimal solution is strictly inside the feasible set, then \(\lambda^*_t = 0\) and the solution \(u^*_{\nu,t}\) coincides with \(u^*_t\).

For controller synthesis we define the following functions, which can be interpreted as modified gradients of (4):

\[
L_{u,t}(u, y, \lambda) := \nabla \phi_t(u) + G^T \nabla \psi_t(y) + G^T K_t \lambda,
\]

\[
L_{\lambda,t}(y, \lambda) := K_t y - e_t - \nu \lambda,
\]

where we note that, with respect to the gradients of \(\tilde{L}_{\nu,t}\), in \(L_{u,t}\) and \(L_{\lambda,t}\) the map \(Gu + Hw_t\) has been replaced by variable \(y\). Using (7), we propose the following **online projected primal-dual controller** applied to (1) (see Fig. 1):

\[
\tilde{z} := \xi + \epsilon x = Ax + Bu + Ew_t,
\]

\[
u := \tilde{P}_t(u - \eta L_{u,t}(u, y, \lambda)) - u,
\]

\[
\dot{\lambda} = \tilde{P}_t(\lambda + \eta L_{\lambda,t}(y, \lambda)) - \lambda,
\]

where \(\epsilon, \eta > 0\) are plant and controller gains that induce a time-scale separation between the plant and the controller, and we establish explicit convergence error bounds.

B. Stability and Tracking Analysis

In this section we characterize the transient behavior of (8). To this aim, in what follows we use the notation:

\[
z := (u, \lambda), \quad \tilde{z} := z - z_{\nu,t}^*,
\]

\[
u := \tilde{P}_t(u - \eta L_{u,t}(u, y, \lambda)) - u,
\]

\[
\dot{\lambda} := \tilde{P}_t(\lambda + \eta L_{\lambda,t}(y, \lambda)) - \lambda,
\]

where \(\epsilon, \eta > 0\) are plant and controller gains that induce a time-scale separation between the plant and the controller, and we establish explicit convergence error bounds.

\[
\xi := (x, z), \quad \xi_{\nu,t}^* := (x_{\nu,t}^*, z_{\nu,t}^*), \quad \dot{\xi} := \xi - \xi_{\nu,t}^*.
\]
to the joint state of (8), the saddle-point of (4), with $x_{r,t}^* = -A^{-1}(Bu_{r,t}^* + Hw_t)$, and the tracking error, respectively. We begin by characterizing the existence of solutions.

**Lemma 3.2:** Let Assumptions [2][4] hold. For each $\xi_0 = \langle x_0, u_0, \lambda_0 \rangle \in \mathbb{R}^{n + m + r}$, there exists a unique solution $\xi(t)$ of (8) with $\xi(0) = \xi_0$. Moreover, $\xi$ is continuously differentiable and it is maximal, i.e., it is defined for all $t \in \mathbb{R}_{\geq 0}$.

**Proof:** This claim follows from the following facts: (i) the projection mapping is globally Lipschitz [29], [30], (ii) under Assumptions [2][4] the maps $L_{\lambda}(u, y, \lambda)$ and $L_{\lambda} \xi(y, \lambda)$ are globally Lipschitz in $(u, y, \lambda)$ uniformly in $t$, and locally Lipschitz with respect to $t$, (iii) the composition of globally Lipschitz functions is globally Lipschitz, and (iv) under Assumption [4] the plant dynamics are locally Lipschitz in $t$. □

Lemma 3.2 guarantees that the trajectories of (8) are continuously differentiable (see Fig. 2). Moreover, since trajectories are maximal, Lemma 3.2 guarantees that trajectories have no finite escape time. The latter property is leveraged to prove the following result, which establishes attractiveness and forward invariance of the feasible set (see [30, Thm. 3.2]).

**Lemma 3.3:** Let Assumptions [2][4] hold. If $u(t_0) \not\in U$ (resp. $\lambda(t_0) \not\in C$) for some $t_0 \in \mathbb{R}_{\geq 0}$, then the trajectory $u(t)$ (resp. $\lambda(t)$) approaches exponentially the set $U$ (resp. the set $C$) for $t > t_0$. If $u(t) \in U$ (resp. $\lambda(t) \in C$) for some $t_0 \in \mathbb{R}_{\geq 0}$, then $u(t) \in U$ (resp. $\lambda(t) \in C$) for all $t \geq t_0$.

**Remark 4:** Lemma 3.3 guarantees that, if $u(t_0) \in U$, then the constraint $u(t) \in U$ is satisfied for all $t \geq t_0$. In contrast, because the constraint (15) is dualized in (4), the inequality $K_{t}y(t) \leq \epsilon_t$ is guaranteed to hold only asymptotically, even when $K_{t}y(t_0) \leq \epsilon_t$ for some $t_0 \in \mathbb{R}_{\geq 0}$.

The following lemma establishes a relationship between the saddle-point of the regularized Lagrangian (4) and the equilibrium of (8). The proof is omitted due to space limitations.

**Lemma 3.4:** For any $t \in \mathbb{R}_{\geq 0}$ and for any fixed $w_t \in \mathbb{R}^q$, let $\xi_{eq} := \langle x_{eq}, u_{eq}, \lambda_{eq} \rangle$ denote an equilibrium of (8). If Assumptions [2][4] hold, then $\xi_{eq}$ is unique and it coincides with the unique saddle-point of (4), as defined by (11).

To characterize the transient behavior of (8), we first show that, when the dynamics of the plant (1) are infinitely fast, the controller (8b)-(8c) converges exponentially to the saddle-point of the regularized Lagrangian, modulo an asymptotic error that depends on the time-variability of the optimizer $\tilde{z}_r$.

**Proposition 3.5:** Let Assumptions [2][4] hold, let $\mu := \min\{\mu_0, \nu\}$, $\ell := \sqrt{2}(K + \max\{\ell_u + ||G||^{2}\ell_y, \nu\})$. If $\varepsilon = 0$ and the controller gain satisfies $\eta < \frac{2\mu}{2\mu + \frac{\varepsilon^2}{2}}$, then for any $t_0 \in \mathbb{R}_{\geq 0}$:

$$
\|z_r(t)\| \leq e^{-\frac{2\mu}{2\mu + \frac{\varepsilon^2}{2}}(t-t_0)}|z_r(t_0)| + \frac{2}{\rho_2} \varepsilon \sup_{\tau \geq t_0} \|z_r^\tau\|, \quad (12)
$$

for all $t \geq t_0$, where $\rho_2 = \eta(\mu - \frac{\varepsilon^2}{2})$, and $z_r^\tau$ denotes the controller tracking error as in (10).

The proof of this result is postponed to Appendix A. Proposition 3.5 guarantees that (8) is input-to-state stable [14] with respect to the time derivative of the optimizer (here, $z_r^\tau$ denotes the distributional derivative [31] of $z_r^\tau$, see Remark 2). Notice that the rate of convergence $\rho_2$ can be tuned by properly tuning the controller gain $\eta$.

**Remark 5:** We note that, under Assumptions [2][4] the saddle-point trajectory $t \mapsto z_r^\tau$ is locally Lipschitz and hence absolutely continuous on compact sets. Thus, the essential supremum of $\|z_r^\tau\|$ is well defined. To see this, notice that, $z_r^\tau$ solves the following Variational Inequality:

$$(u - u_{\star,t})(\nabla \psi(u_{\star,t}) + G^T \nabla \phi(Gu_{\star,t} + Hw_t) + G^T K_{t}^\tau \lambda_{r,t}) \geq 0,$$

which holds for all $u \in U$, $\lambda \in C$, and for all $t \in \mathbb{R}_{\geq 0}$. It follows from Assumptions [2][4] and from our regularization method (4) that the mapping defining the above variational inequality is locally Lipschitz in $(u, \lambda)$, and thus [32, Cor. 2B.3] guarantees that $z_r^\tau$ is locally Lipschitz. Hence, by Rademacher’s theorem [33, Thm. 23.2], $t \mapsto z_r^\tau$ is differentiable almost everywhere (a.e.). □

Next, we provide a sufficient condition on the time-scale separation between the plant (5a) and the feedback controller (8b)-(8c) to ensure convergence to the optimal trajectory.

**Theorem 3.6:** Let Assumptions [2][4] hold, let $\ell := \sqrt{2}(K + \max\{\ell_u + ||G||^{2}\ell_y, \nu\})$ and $\mu := \min\{\mu_0, \nu\}$. If

$$
\eta < \frac{4\mu}{\ell^2} \quad \text{and} \quad \varepsilon < \frac{\rho_2 \ell}{4\mu} \frac{\|P_2 A^{-1}B\|\|\Psi\|}{\ell^2}, \quad (13)
$$

where $\rho_2 = \eta(\mu - \frac{\varepsilon^2}{2})$, $\Psi = \rho_2 \ell u |G||G| + \sqrt{2} |C||\ell_y| |G| + Kk_0$, $k_0 = \max\{2 + \eta \ell_u + \ell_y |G||G|^2, |G||K|\}$, and $P_2, Q_x$ are as in Assumption [11] then for any $t_0 \in \mathbb{R}_{\geq 0}$:

$$
\|\tilde{\xi}_r(t)\| \leq \sqrt{\kappa} \|\xi_{eq}(t_0)\| e^{-\frac{2\mu}{2\mu + \frac{\varepsilon^2}{2}}(t-t_0)} + \frac{2}{\rho_2} \varepsilon \|w_r^0\| \quad \text{and} \quad \|w_r^\tau\| \leq \frac{4\varepsilon}{\rho_2 \ell^2} \|P_2 A^{-1}E\| \varepsilon \sup_{\tau \geq t_0} \|w_r^\tau\|, \quad (14)
$$

for all $t \geq t_0$, where $\rho_2 = \eta(\mu - \frac{\varepsilon^2}{2})$, $\ell = \sqrt{2}(K + \max\{\ell_u + ||G||^{2}\ell_y, \nu\})$ and $\xi_{eq}$ is as in (11).

The proof of this result is presented in Appendix A. Theorem 3.6 shows that, under a sufficient separation between the time scales of the plant and of the controller, the trajectories of (8) globally exponentially converge to $z_r^\tau$, (which we recall is the trajectory of the unique saddle-point of the regularized Lagrangian), modulo an asymptotic error that depends on the time-variability of the optimizer and of the exogenous disturbance. Precisely, Theorem 3.6 guarantees that (8) is input-to-state stable [14] with respect to $z_r^\tau$ and $w_r$, where $w_r$ denotes the distributional derivative [31] of $w_r$ (notice that, under Assumption [2][4], $\tau \mapsto w_r^\tau$ is differentiable a.e.).

Two important observations are in order. First, the upper bound for $\varepsilon$ is an increasing function of $\Lambda(Q_x)$ and $\rho_2$, that are interpreted as the convergence rate of the open-loop plant and of the controller with $\varepsilon = 0$, respectively. Moreover, the bound is a decreasing function of $\|P_2 A^{-1}E\|$. Since $\|A^{-1}\| \rightarrow 0$ when the eigenvalues of $A$ are approaching the open right complex plane, the latter term takes into account the margin of the open-loop plant. Second, we note that the rate of convergence $\rho_2$ is governed by the quantities $\mu_0$ and $\varepsilon$ (as well as matrices $P_2$ and $Q_x$), which are interpreted as the rate of convergence of the controller with $\varepsilon = 0$ and the rate of convergence of the open-loop plant, respectively.
Remark 6: The bound (14) depends on two main quantities: $\text{ess sup}_{\tau \ge t_0} \| z^*_\sigma,\tau \|$, which captures the time-variability of $z^*_\sigma,\tau$, and $\text{ess sup}_{\tau \ge t_0} \| \dot{w}_\tau \|$, which captures the shift in the equilibrium of (1) induced by the time-varying exogenous input $w_\tau$. Notably, when the optimization problem [3] is time-invariant and $w_\tau$ is constant, (14) simplifies to an exponential stability result, of the form $\| \xi(t) \| \leq \sqrt{\kappa} \| \xi(t_0) \| e^{-\frac{1}{2} \gamma(t-t_0)}$. \hfill $\square$

C. Extensions
Our analysis suggests that the results can be extended in different directions. Here, we discuss two possible extensions.

1) Switched LTI Plants with Common Quadratic Lyapunov Functions: Theorem 3.6 can be extended to consider switched LTI plants of the form:

$$\dot{x} = A_\sigma x + B_\sigma u + E_\sigma w_\tau,$$

$$y = C_\sigma x + D_\sigma w_\tau,$$

where $\sigma : \mathbb{R}_{\ge 0} \rightarrow Q$ is a switching signal taking values in the finite set $Q$. When all modes of (15) have a common equilibrium point $x^*_\sigma = A^{-1}_\sigma B_\sigma + A^{-1}_\sigma E_\sigma w_\tau$ for all values of $\sigma$ and admit a common quadratic Lyapunov function $V$, the same construction for the Lyapunov function (12) can be used to establish exponential ISS of the closed-loop system. Since in this case $G$ and $H$ in (2) are also common across the modes, the bounds in Theorem 3.6 still hold unchanged. This scenario emerges in applications where mode-dependent inner feedback controllers are implemented to stabilize each mode of the plant (so that all modes share a common equilibrium point [34]), but different controllers lead to different closed-loop transient performance. Note, however, that having a stable autonomous switched LTI system does not necessarily imply the existence of a common quadratic Lyapunov function. Instead, it implies the existence of a common quadratic Lyapunov function that is homogeneous of degree 2, e.g., piece-wise quadratic [35]. When matrices $C_\sigma$ and $D_\sigma$ are mode-dependent, Theorem 3.6 can also be extended, provided that the pair $(G, H)$ remains common across modes and that (13) and (14) are modified to account for the worse-case bound among all modes.

2) Switched Plants with Average Dwell-Time Constraints: When the switched system (15) does not admit a common Lyapunov function, it is still possible to obtain a result of the form (14), provided the switching is slow “on the average”. In particular, if the switching signal $\sigma$ satisfies an average dwell-time constrain of the form

$$N_\sigma(t, \tau) \leq \eta_0(t-\tau) + N_0,$$

where $N_\sigma(t, \tau)$ denotes the number of discontinuities of $\sigma$ in the open interval $(t, \tau)$, $\eta_0 \in \mathbb{R}_{\ge 0}$ denotes the switching signal dwell-time, and $N_0 \ge 0$ is a chatter bound that guarantees that the number of consecutive switches is finite at every time. In this case, it is possible to choose the controller gain $\eta$ sufficiently small such that the exponential stability property of the switched system is preserved, and the same construction (32) carries over. This observation follows directly from the Lyapunov construction presented in [13], which permits the derivation of a result similar to Proposition 3.8 using quadratic Lyapunov functions. Characterizations of the conditions that emerge between $\eta$ and the time-scale separation parameters $(\varepsilon, \eta)$ can also be explicitly derived as in [13]. However, unlike the results of [13], the results of this paper allow to consider online optimization problems with constraints. To the best of our knowledge, similar results for online optimization with constraints of switched systems have not been studied before.

IV. ONLINE PRIMAL-DUAL GRADIENT FLOW
In this section, we consider the problem of regulating (1) to the solution of the following optimization problem:

$$\begin{align}
(u_t^*, y_t^*) := & \arg \min_{u \in \mathbb{R}^m, y \in \mathbb{R}^p} \phi(u) + \psi(y), \\
\text{s.t.} \quad & y = Gu + Hw_t, \quad K_t y = e_t,
\end{align}$$

(17a)

(17b)

which contains only equality constraints on the system outputs. In contrast with the method proposed in Section III which guarantees tracking of an approximate optimizer, in this section we will show that, when the optimization problem includes only equality constraints, we can guarantee tracking of the exact optimizer (this behavior is achieved without resorting to a regularized Lagrangian).

A. Controller Synthesis
We begin by imposing the following assumption.

Assumption 5: The columns of $K_t G$ are linearly independent and there exists $\bar{k}, \bar{k} \in \mathbb{R}_{\ge 0}$ such that $\bar{k} I \preceq K_t GG^T K_t^T \preceq \bar{k} I$ for all $t$. \hfill $\square$

Since problem (17) contains only equality constraints, Assumption 5 is sufficient to guarantee uniqueness of the optimal multipliers [16]. In what follows, for notation simplicity we will state the results by considering a time-invariant constraint matrix $K$. The stated results directly extend to the case of time-varying matrices, as noted in pertinent remarks.

We consider the following Lagrangian function for (17):

$$L_t(u, \lambda) = \phi(u) + \psi_t(Gu + Hw_t) + \lambda^T(K(Gu + Hw_t) - e_t),$$

(18)

where $\lambda \in \mathbb{R}_{\ge 0}^p$ is the vector of dual variables. Under Assumptions 2 and 5 the unique minimizer $(u^*_t, y^*_t)$ of (17) solves the following Karush–Kuhn–Tucker (KKT) conditions:

$$0 = \nabla \phi(u_t^*) + G^T \nabla \psi_t(Gu_t^* + Hw_t) + G^T K^T \lambda^*_t,$nabla \phi(u_t^*) + G^T \nabla \psi_t(Gu_t^* + Hw_t) + G^T K^T \lambda^*_t,$$

(19a)

$$0 = K(Gu_t^* + Hw_t) - e_t.$$nabla \phi(u_t^*) + G^T \nabla \psi_t(Gu_t^* + Hw_t) + G^T K^T \lambda^*_t,$$nabla \phi(u_t^*) + G^T \nabla \psi_t(Gu_t^* + Hw_t) + G^T K^T \lambda^*_t,$$

(19b)

(19c)

To synthesize a controller, we define the following functions, which can be interpreted as modified gradients of the Lagrangian function:

$$L_{u,t}(u, y, \lambda) := \nabla \phi(u) + G^T \nabla \psi(y) + G^T K^T \lambda,$nabla \phi(u) + G^T \nabla \psi(y) + G^T K^T \lambda,$$

(20a)

$$L_{\lambda,t}(y) := Ky - e,$nabla \phi(u) + G^T \nabla \psi(y) + G^T K^T \lambda,$$

(20b)

$$\dot{\lambda} = \eta_c L_{\lambda,t}(y),$$nabla \phi(u) + G^T \nabla \psi(y) + G^T K^T \lambda,$$

(20c)

where (similarly to (7)) with respect to the gradients of $L_t(u, \lambda)$, the steady-state map $Gu_t + Hw_t$ has been replaced by the variable $y$. We then consider the following online primal-dual gradient controller applied to the plant (1):

$$\begin{align}
\ddot{x} &= Ax + Bu + Fw_t, \quad y = Cx + Dw_t, \\
\dot{u} &= -\eta \dot{u} L_{u,t}(u, y, \lambda), \\
\dot{\lambda} &= \eta \dot{\lambda} L_{\lambda,t}(y),
\end{align}$$

(20a)

(20b)

(20c)
where \( \varepsilon, \eta_u, \eta_\lambda \in \mathbb{R}_{\geq 0} \) are plant and controller gains. Similarly to the projected controller in Section III, the controller (20b)–(20c) uses output-feedback from the plant, and does not require any knowledge on \( w_t \). In the following lemma, we relate the time-varying equilibria of (20) with the solution of (17). To this aim, in what follows we use the notation:
\[
\ell := (u, \lambda), \quad z^\ast := (u^\ast_t, \lambda^\ast_t), \quad \dot{\zeta} := z - z^\ast, \tag{21}
\]
to denote the controller state, the saddle-point of \( L_t(u, \lambda) \), and the controller tracking error, respectively. Similarly, we use
\[
\xi := (x, z), \quad \xi^* := (x^*_t, z^*_t), \quad \dot{\xi} = \xi - \xi^*, \tag{22}
\]
to denote the joint state of (20), the saddle-point of \( L_t(u, \lambda) \), with \( x^*_t = -A^{-1}(B u^*_t + H w_t) \), and the joint plant and controller tracking error, respectively.

Lemma 4.1: For any fixed \( w_t \in \mathbb{R}^q \), let \( \xi_{eq} := (x_{eq}, u_{eq}, \lambda_{eq}) \) denote an equilibrium of (20). If Assumptions 1–5 hold, then \( \xi_{eq} \) is unique and it coincides with the unique solution of (18).

The proof of this claim is omitted due to space limitations. Differently from Lemma 3.2, that guarantees equivalence between the equilibrium point of the controlled system and an approximate optimizer (defined as the saddle point of the augmented Lagrangian), Lemma 4.1 establishes that the equilibrium point of (20) coincides with the exact optimizer (namely, the saddle point of the (non-augmented) Lagrangian).

B. Stability and Tracking Analysis

We now investigate the transient behavior of the controlled system (20). We begin by showing that, when (1) is infinitely fast, (20) converges exponentially to the solution of (3).

Proposition 4.2: Let Assumptions 1–5 hold, let
\[
P_z := \begin{bmatrix} \ell I & G^T K^T \\ K G & \frac{1}{4} I \end{bmatrix}, \tag{23}
\]
where \( \ell := \ell_u + \|G\|^2 \ell_p \), If \( \varepsilon = 0 \) and the controller parameters are such that \( \eta_u > \frac{1}{4k} \lambda_\nu \), then for any \( t_0 \in \mathbb{R}_{\geq 0} \):
\[
\|\dot{\zeta}(t)\| \leq \sqrt{\kappa} \|\zeta(t_0)\| e^{-\frac{1}{2} \rho_z(t-t_0)} + \frac{4}{\lambda(Q_z)} \|P_z\| \parallel \kappa \parallel \sup_{\tau \geq t_0} \|\dot{\zeta}^*_\tau\|, \tag{24}
\]
for all \( t \geq t_0 \), \( \rho_z := \frac{1}{4} \min\{\eta_u k / \ell, \eta_u q_2 \} \), \( \kappa := \frac{\lambda(P_z)}{\lambda(Q_z)} \), where \( \dot{\zeta} \) denotes the controller tracking error as in (21).

The proof of this result is presented in Appendix B. Proposition 4.2 guarantees that (3) is input-to-state stable [14] with respect to \( \dot{\zeta}^*_\tau \). Two comments are in order. First, differently from [16, Theorem 1], Proposition 4.2 shows that \( \rho_z \) can be made arbitrarily large by properly tuning the parameters \( \eta_u \) and \( \eta_\nu \). Second, we note that the tracking result (24) is in the spirit of [20, Section 6]; however, in [20] the primal-dual dynamics are assumed to be differentiable with respect to \( t \) (in contrast, we require milder conditions of absolute continuity).

Remark 7: When the matrix \( K \) is time-varying, then \( P_z \) in (23) and the coefficient \( \kappa \) in (24) are also time-varying. In this case, the result (24) extends by replacing \( \kappa \) with \( \sup_{\tau} \kappa_\tau \) and the coefficient \( \frac{\|P_z\| \sqrt{\kappa}}{\lambda(Q_z)} \) with \( \sup_{\tau} \frac{4\|P_z\| \sqrt{\kappa_\tau}}{\lambda(Q_z)} \).

We now present sufficient conditions on the time-scale separation between the plant and controller dynamics that result in exponential stability properties of the system (20).

Theorem 4.3: (Stability and Tracking of (20)) Let Assumptions 1–5 hold and let \( P_x, Q_x \) be as in Assumption 1. Suppose that \( \varepsilon \) satisfies
\[
\varepsilon < \frac{\rho_z \lambda(P_z) |\lambda(P_z)|}{16 \sigma_1 \sigma_2 + 4 \rho_z \lambda(P_z) \sigma_3}, \tag{25}
\]
where \( P_z, \rho_z \) are as in Proposition 4.2 and
\[
\sigma_1 := 2 \eta_u \ell_p C ||G|| (\ell + ||KG||) + 2 \eta_u ||G^T K^T K C|| + 2 \ell \eta_u ||KC||, \quad \sigma_2 := 2 \eta_u \ell ||P_x A^{-1} B|| + 2 \eta_u ||P_x A^{-1} G G^T K^T||, \quad \sigma_3 := 2 \eta_u \ell ||C|| ||P_x A^{-1} BG||. \tag{26}
\]
Then, for any \( t_0 \in \mathbb{R}_{\geq 0} \), the tracking error (22) satisfies:
\[
\|\dot{\zeta}(t)\| \leq \sqrt{\kappa} \|\zeta(t_0)\| e^{-\frac{1}{2} \rho_z (t-t_0)} + \frac{4}{\lambda(Q_z)} \|P_z\| \sqrt{\kappa} \sup_{\tau \geq t_0} \|\dot{\zeta}^*_\tau\|, \tag{27}
\]
for all \( t \geq t_0 \), \( \kappa := \max\{\lambda(P_x), \lambda(P_z)\} / \min\{\lambda(P_x), \lambda(P_z)\} \), \( \rho_z := \frac{1}{4} \min\{\rho_z \lambda(P_z) / \lambda(Q_z), e^{-1} \lambda(Q_z) / \lambda(P_z)\} \).

The proof of this result is postponed to Appendix B. Precisely, Theorem 4.3 guarantees that (8) is input-to-state stable [14] with respect to \( \dot{\zeta}^*_\tau \). The bound on \( \varepsilon \) is an increasing function of \( \lambda(P_x) \) and \( \lambda(P_z) \), which are the convergence rates of the open-loop plant and of the controller with \( \varepsilon = 0 \), respectively. Moreover, we note that the rate of convergence \( \rho_z \) is governed by the quantities \( \rho_z \) and \( \varepsilon \) (as well as matrices \( P_x, Q_x \), and \( P_z \)), which are interpreted as the rates of convergence of the controller with \( \varepsilon = 0 \) and the rate of convergence of the open-loop plant. Finally, we note that the bound (27) can be readily extended to account for time-varying matrices \( K_t \) by adopting a reasoning similar to that in Remark 7.

V. APPLICATION TO RAMP METERING CONTROL

In this section, we apply the proposed framework to the control of on-ramps in a network of traffic highways.

1The code used in our simulations is publicly available at https://github.com/gianlucaB1/onlinePrimalDual_rampMetering
To describe the traffic evolution, we adopt a continuous-time version of the Cell-Transmission Model (CTM) [36]. We model a traffic network as a directed graph $G = (V, L)$, where $V$ models the set of traffic junctions (nodes) and $L \subseteq V \times V$ models the set of highways (links). We partition the set of links into three disjoint sets: $L = L_{\text{on}} \cup L_{\text{off}} \cup L_{\text{in}}$, where $L_{\text{on}}$ denotes the set of on-ramps where vehicles can enter the network, $L_{\text{off}}$ denotes the set of off-ramps where vehicles can exit the network, and $L_{\text{in}}$ denotes the set of internal links.

For $i \in L$, we denote by $i^+$ the set of downstream links, and by $i^-$ the set of upstream links. For all $i \in L$, we let $x_i : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ be the density of vehicles in the link. We model the dynamics of all links $i \in L$ according to the CTM with first-in-first-out (FIFO) allocation policy [36]:

$$\dot{x}_i = -f_{\text{out}}^i(x) + f_{\text{in}}^i(x),$$

$$f_{\text{out}}^i(x) = \min \{d_i(x), \{s_j(x_j) / r_{ij}\}_{j \in i^-}\},$$

$$d_i(x) = \min \{\varphi_i x_i, d_{i}^{\text{max}}\},$$

$$s_i(x) = \min \{\beta_i(x_{i}^{\text{jam}} - x_i), s_i^{\text{max}}\},$$

$$f_{\text{in}}(x) = \sum_{j \in i^+} f_{\text{out}}^j(x),$$

where $d_i : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ and $s_i : \mathbb{R}_{\geq 0} \to \mathbb{R}_{\geq 0}$ are the link demand and supply functions, respectively, $r_{ij} \in [0, 1]$ is the routing ratio from $i$ to $j$, with $\sum_j r_{ij} = 1$, $\varphi_i > 0$. In our simulations, we used identical and uniform routing ratios at each junction. We refer to Fig. 3 for an illustration of the network topology used in our simulations, and to Fig. 4 for a description of the parameters that characterize demand and supply. For simplicity, all links are assumed to be identical. The dynamics of on-ramps and off-ramps coincide with those of (28), where inflow and outflow functions are replaced by:

$$f_{\text{in}}^i(x) := u_i,$$

$$f_{\text{out}}^i(x) := d_i(x_i),$$

where we assume the availability of measurements that provide a noisy estimate of the traffic densities in the highways: $y_i = x_i + w_i$, for all $i \in L$, where $w_i : \mathbb{R}_{\geq 0} \to \mathbb{R}$. Finally, we define the network throughput as the sum of all exit flows from the off-ramps $\Phi(x) := \sum_{i \in L_{\text{off}}} f_{\text{out}}^i(x)$. The on-ramp metering problem is formalized as follows.

**Problem 2: (Ramp Metering)** Given a vector of on-ramp flow demands $u_{\text{ref}} \in \mathbb{R}^m$, select the set of metered flows on the on-ramps $(u_1, \ldots, u_m)$ such that $u$ and $x$ minimize the cost $(u - u_{\text{ref}})^T Q_u (u - u_{\text{ref}}) - \Phi(x)$, subject to the constraints (28)-(29), where $Q_u \in \mathbb{R}^{n \times n}$ is symmetric and positive definite. □

We compare three control strategies, described next.

1) **Online Primal-Dual Controller:** To solve Problem 2, we assume that for all $i \in L$, the inequality $d_{i}^{\text{max}} \leq s_{i}^{\text{max}}$ holds for all $j \in i^+$. Under this assumption, if the network is operated in a regime in which $x_i \leq \min \{x_{i}^{\text{jam}}, x_{i}^{\text{crit}}\}$ for all $i \in L$ (i.e., all highways operate in the free-flow regime), then the dynamics (28) simplify to the following linear model:

$$\dot{x}_i = -f_{\text{out}}^i(x) + f_{\text{in}}^i(x),$$

$$f_{\text{in}}^i(x) = \varphi_i x_i, f_{\text{out}}^i(x) = \sum_{j \in i^+} f_{\text{out}}^j(x).$$

(30)

In vector form, (30) can be written as $\dot{x} = (R^T - I) F x + Bu$, and $y = x + w$, where $R := [r_{ij}]$, and $F := \text{diag}(\varphi_1, \ldots, \varphi_n)$. Notice that matrix $(R^T - I) F$ is Hurwitz (see e.g. [3, Theorem 1]). Building on this, we propose the following problem:

$$\min_{u,y} (u - u_{\text{ref}})^T Q_u (u - u_{\text{ref}}) - \Phi(y),$$

s.t. $y = -(R^T - I) F^{-1} B u + w,$

$$u_i \geq 0, \quad y_i \leq \min \{x_{i}^{\text{crit}}, x_{i}^{\text{jam}}, x_{i}^{\text{crit}}\}, \forall i \in L.$$

(31)

The optimization problem (31) formalizes the objectives of the ramp metering problem, while guaranteeing that all highways are operated in the free-flow regime.

2) **Distributed Reactive Metering using ALINEA:** ALINEA [26] is a distributed metering strategy that has received considerable interest thanks to its simplicity of implementation and to its effectiveness. Given a controllable on-ramp $i \in L_{\text{in}},$ ALINEA is a reactive controller that takes the form $\dot{u}_i = \sum_{j \in i^+} K_j (\hat{x}_j - x_j)$, where $\hat{x}_j \in \mathbb{R}_{\geq 0}$ is a desired setpoint and $K_j$ are tunable controller gains. In our simulations, we let the setpoint be $\hat{x}_j = \min \{x_{j}^{\text{crit}}, x_{j}^{\text{jam}}\}$.

3) **Model Predictive Control (MPC):** MPC is a receding-horizon control algorithm that computes an optimal control input based on a prediction of the system’s future trajectory according to the system’s dynamics. We consider a formulation of MPC where the optimization problem is solved every $T_s \in \mathbb{R}_{\geq 0}$ time instants with prediction horizon $T_p \in \mathbb{R}_{\geq 0},$

$$\min_{u} (u - u_{\text{ref}})^T Q_u (u - u_{\text{ref}}) - \Phi(y),$$

s.t. $y = -(R^T - I) F^{-1} B u + w,$

$$u_i \geq 0, \quad y_i \leq \min \{x_{i}^{\text{crit}}, x_{i}^{\text{jam}}, x_{i}^{\text{crit}}\}, \forall i \in L.$$

(31)
with $T_p > T_s$. In our simulations, we discretized the dynamics with $T_p = 200$ min, $T_s = 50$ min, and we used the cost function $\sum_{k=0}^{T_p} (u(k) - u^{ref})^T Q_u (u(k) - u^{ref}) - \Phi(x(k))$.

**Discussion:** Fig. 5 compares the performance of the three controllers in the noiseless case (i.e., where $w_t = 0$ at all times for all $i \in L$). The simulation demonstrates that our method and MPC achieve the largest network throughput, outperforming ALINEA. Moreover, the constraint violation plot (right figure) shows that both our method and MPC are able to maintain the network in a regime near the free-flow conditions. Notice that, while for MPC this regime is precisely modeled through the predictions, the primal-dual controller maintains the system in such regime thanks to the constraints in (31). Finally, although ALINEA largely outperforms absence of on-ramp metering control, it critically suffers from its distributed architecture, making it suboptimal.

Fig. 6 compares the performance of our controller with that of MPC in a scenario with time-varying output disturbance (depicted in green). The simulation suggests that there are two main benefits that adopting primal-dual controllers as compared to MPC: (i) because the primal-dual controller uses instantaneous feedback from the system, it can react faster to unmodeled dynamics or time-varying disturbances, and (ii) in contrast with MPC where an optimization problem must be solved to convergence at the beginning of every time-window $[0, T_s]$, the primal-dual controller performs only one gradient-like step at every time.

**VI. CONCLUSIONS**

We have leveraged online primal-dual dynamics to develop an output controller that regulates an LTI plant to the solution of a time-varying optimization problem. For optimization problems with input constraints and output inequality constraints, we leveraged an augmented Lagrangian function and established exponential convergence to an approximate solution of the optimization problem. For optimization problems with output equality constraints, we established exponential convergence to an interval around the exact optimal solution trajectory. Our convergence bounds capture the time-variability of the optimal solution due to time-varying costs and constraints as well as the variation of the exogenous input.

**APPENDIX A**

**ANALYSIS OF PROJECTED SADDLE-POINT CONTROLLER**

In this section, we present the proof of Proposition 3.5 and Theorem 3.6. For the subsequent analysis, it is convenient to define the following time-varying map:

$$F_t(z) := \nabla \phi_t(u) + G^T \nabla \psi_t(Gu + Hw_t) + G^T K_f^I \lambda$$

\[32\]

**1) Proof of Proposition 3.5** We consider only the case where the ess-sup in (12) is bounded since otherwise the bound holds trivially. Recall that $z := (u, \lambda)$. We note that, when $\varepsilon = 0$, the dynamics (8) can be rewritten as:

$$\dot{z} = P_H(z - \eta F_t(z)) - z,$$

\[33\]

where $\Omega := \mathcal{U} \times \mathcal{C}$. Proposition 3.5 leverages this structure as well as four auxiliary lemmas. The following lemma follows directly from [37, Lemma 6] and [18].

**Lemma A.1:** Let Assumption $2$ hold. Then, for any $t \geq 0$, $u, u' \in \mathbb{R}^m$ and $y, y' \in \mathbb{R}^p$, there exist symmetric matrices $T_{u,t} \in \mathbb{R}^{m \times m}$ and $T_{y,t} \in \mathbb{R}^{p \times p}$, such that $\mu_t I \leq T_{u,t} \leq \ell_u I$ and $0 \leq T_{y,t} \leq \ell_y I$, such that $\nabla \phi_t(u) - \nabla \phi_t(u') = T_{u,t}(u - u')$ and $\nabla \psi_t(y) - \nabla \psi_t(y') = T_{y,t}(y - y')$.

Although the time-varying matrices $T_{u,t}$ and $T_{y,t}$ are functions of $u, u'$ and $y, y'$, respectively, this result allows us to leverage the relationships $\mu_t I \leq T_{u,t} \leq \ell_u I$ and $0 \leq T_{y,t} \leq \ell_y I$. Next, we show that $F_t(z)$ is strongly monotone and globally Lipschitz continuous, uniformly in $t$.

**Lemma A.2:** Let Assumption $2$ hold. Then, (32) satisfies:

$$(z - z')^T (F_t(z) - F_t(z')) \geq \min \{\mu_t, \nu\} \|z - z'\|^2$$

\[34\]

for all $z, z' \in \mathbb{R}^{m+r}$, and all $t \in \mathbb{R}_{\geq 0}$.

**Proof:** By expanding the left-hand side of (34), and by using Lemma A.1,

$$(z - z')^T (F_t(z) - F_t(z')) = (u - u')^T (\nabla \phi_t(u) - \nabla \phi_t(u')) + (u - u')^T G^T (\nabla \psi_t(Gu + Hw_t) - \nabla \psi_t(Gu' + Hw_t)) + \nu \|\lambda - \lambda'\|^2$$

$$= (u - u')^T (T_{u,t} + G^T T_{y,t} G)(u - u') + \nu \|\lambda - \lambda'\|^2 \geq \mu_t \|u - u'\|^2 + \nu \|\lambda - \lambda'\|^2 \geq \min \{\mu_t, \nu\} \|z - z'\|^2,$$

which proves the claim.

**Lemma A.3:** Let Assumptions 2 and 3 hold. Then, the mapping (32) satisfies:

$$\|F_t(z) - F_t(z')\| \leq \ell \|z - z'\|,$$

\[35\]

for all $z, z' \in \mathbb{R}^{m+r}$, and all $t \in \mathbb{R}_{\geq 0}$, where $\ell =: \sqrt{2} \max \{\ell_u, \ell_y\} \|G\|^2 + \|G\| \|K_f^I\| \|\lambda - \lambda'\|$.  

**Proof:** Using (7), we directly obtain the bounds:

$$\|L_{u,t}(u, Gu + Hw, \lambda) - L_{u,t}(u', Gu' + Hw, \lambda')\|$$

$$\leq (\ell_u + \ell_y \|G\|^2) \|u - u'\| + \|K\| \|\lambda - \lambda'\|,$$

$$\|L_{\lambda,t}(Gu + Hw, \lambda) - L_{\lambda,t}(Gu' + Hw, \lambda')\|$$

$$\leq \|K\| \|u - u'\| + \nu \|\lambda - \lambda'\|.$$

Finally, the claim follows by using the relationship: $\|u - u'\| + \|\lambda - \lambda'\| \leq \sqrt{2} \|z - z'\|$.  

The following result establishes that the existence of an ISS-Lyapunov function with a particular structure guarantees input-to-state stability with exponential convergence rate, and it is a particular case of [15, Ch. 4] (see also [27]).

Lemma A.4: Consider the system \( \dot{x} = f(t, x, u) \), where \( f: \mathbb{R}_{\geq 0} \times \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n \) is locally Lipschitz in \( t, x, \) and \( u \), and \( t \mapsto u(t) \) is measurable and essentially bounded. If there exists a smooth \( V: \mathbb{R}_{\geq 0} \times \mathbb{R}^n \to \mathbb{R} \) s.t.:
\[
\frac{d}{dt} V(t, x) \leq -b V(t, x), \quad \forall \|x\| \geq b_0 > 0,
\]
hold a.e., then, for all
\[
\int_{t_0}^t a e^{-s b(s-t_0)} ds \leq \frac{1}{b_0^2} \|x(t_0)\|^2 + b_0^2 e^{-b_0 (t-t_0)}, \quad \forall t \geq t_0.
\]

Using the results above, we now present the proof of Proposition 3.5. In particular, we show that the function \( V(\tilde{z}_t) = \frac{1}{2} \|\tilde{z}_t\|^2 \) satisfies the assumptions of Lemma A.4 where we recall that \( \tilde{z}_t \), is as in (40). In what follows, we let \( \tilde{z} := P_{\Omega}(z - \eta F(t, z)) \). By expanding the time-derivative of:
\[
\frac{d}{dt} V(\tilde{z}_t) \leq -\|\tilde{z}_t\|^2 - \eta^2 \|z - \tilde{z}_t\|^2 - \eta \|z - \tilde{z}_t\| \|\tilde{z}_t\| - \mu \|\tilde{z}_t\|^2,
\]
where the first inequality follows by adding and subtracting \( \eta (z - \tilde{z}_t) \) and noting that \( \eta(z - \tilde{z}_t) F_t(z) \leq \|z - \tilde{z}_t\| \|\tilde{z}_t\|. \) Hence, recalling the definitions of \( b \) and \( \rho_z \), (43) satisfies:
\[
\frac{d}{dt} V(\tilde{z}_t) \leq -\|\tilde{z}_t\|^2 + \|\tilde{z}_t\|^2 \|\tilde{z}_t\|^2 - \eta \|\tilde{z}_t\|^2 - \mu \|\tilde{z}_t\|^2,
\]
where the last inequality holds if \( \|\tilde{z}_t\| \geq \eta \|\tilde{z}_t\|^2 + \mu \|\tilde{z}_t\|^2 \).

2) Proof of Theorem 3.6. We consider only cases where the ess-sup in (14) are bounded, otherwise the bound holds trivially. Our proof leverages singular perturbation arguments inspired by [15, Ch. 11]. We first perform a change of variables for (8). Let \( z := (u, \lambda), \tilde{z} := x = A^{-1}Bu + A^{-1}E\dot{w}_t, \)

\[
F_t(z, \tilde{z}) := \begin{bmatrix} L_{u,t}(u, C\tilde{x} + Gu + Hw_t, \lambda) \\ L_{x,t}(C\tilde{x} + Gu + Hw_t, \lambda) \end{bmatrix}.
\]

Then, the dynamics (8) can be rewritten as:
\[
\epsilon \dot{z} = A\tilde{x} + \epsilon A^{-1}BS\tilde{x} + A^{-1}E\dot{w}_t,
\]

(41)

where \( S = [I_m, 0] \) and \( \Omega = \mathbb{R} \times C \). Moreover, let \( b := \eta \|C\| \|f_y\| [G] + \tilde{K} \), and \( g := 2\sqrt{2} \|PA^{-1}B\| \|\tilde{w}_0\| \). To prove the theorem’s statement, we will show that
\[
U(\tilde{z}_t, \tilde{z}) := 1 - \theta \|\tilde{w}_t\|,
\]

(42)

where \( V(\tilde{z}_t) = \frac{1}{2} \|z - \tilde{z}_t\|^2 \). \( W(\tilde{z}_t) = \frac{1}{2} \|\tilde{z}_t\|^2, \) \( W(z) = \frac{1}{2} \|z\|^2 \). The time-derivative of \( V(\tilde{z}_t) \) along the trajectories of (41) reads:
\[
\frac{d}{dt} V(\tilde{z}_t) = -\frac{\epsilon}{2} V(\tilde{z}_t) - \frac{\eta \epsilon}{4} \|\tilde{z}_t\|^2
\]

(43)

almost everywhere. The first term satisfies:
\[
\frac{d}{dt} V(\tilde{z}_t) = \frac{\epsilon}{2} V(\tilde{z}_t) - \frac{\eta \epsilon}{4} \|\tilde{z}_t\|^2
\]

(44)

and the second inequality follows from the non-expansiveness of the projection operator, namely:
\[
\frac{d}{dt} V(\tilde{z}_t) - V(z_t, 0) \leq \frac{\eta \epsilon}{4} \|\tilde{z}_t\|^2
\]

(45)

where the last inequality holds if \( \|\tilde{z}_t\| \geq \eta \|\tilde{z}_t\|^2 \) and \( \|\tilde{z}_t\| \). The time-derivative of \( W(\tilde{z}) \) along the trajectories of (41):
By expanding the terms:

\[ \|S\hat{z}\| = \|S(P_d(z - \eta F(z, \hat{x})) - \hat{z})\| \]

and

\[ = \|S(P_d(z - \eta F(z, \hat{x})) - z - P_d(z - \eta F(z, \hat{x}^*, 0)) + z^*_t)\| \]

\[ \leq \|L_{u,t}(u, C\hat{x} + Gu + Hw_t, \lambda) \]

\[- L_{u,t}(u^*, Gu^* + Hw_t, \lambda^*)\| + 2\|u - u^*\| \]

\[ \leq \sqrt{2} \max\{2 + \eta u + \ell u, \|G\|/2\}, \|K\|G\|/\|\hat{x}\|, \]

where the first inequality follows from the non-expansiveness of the projection operator and the second inequality follows from Assumption 2. By recalling the definition of \(g\), by letting \(d = 2\eta_{\ell y} ||P A^{-1}B|| ||C|| ||G||\), and by substituting into (45):

\[ \frac{d}{dt} W(\hat{x}) \leq -\varepsilon^{-1} A(Q_x) \|\hat{x}\|^2 + 2\|\hat{x}\|^2 \]

\[ + g(\|\hat{x}\|_2^2 + 2\|P_x^{-1}B\| \|\hat{x}\|_2 \|\hat{w}_t\| \]

\[ \leq -\frac{\lambda(Q_x)}{2\varepsilon} \|\hat{x}\|^2 + 2\|\hat{x}\|^2 + g(\|\hat{x}\|_2^2), \quad (46) \]

where the last inequality is satisfied if \(\|\hat{x}\| \geq 4\varepsilon \|P_x^{-1}E\| \sup \|\hat{w}_t\|\). By combining (44)(46):

\[ \frac{d}{dt} U(\hat{x}, \hat{z}_v) \leq \varepsilon T \Lambda \hat{z} - \frac{1}{2} \min\{2\rho_z, \frac{\lambda(Q_x)}{2\varepsilon} \|P_x\| \}

\[ = \left[ \begin{array}{cc}
1 - (\theta - \theta^2) & -\frac{1}{2} \left( (\theta - \theta^2) b + \theta g \right) \\
\frac{1}{2} \left( (1 - \theta) b + \theta g \right) & \lambda(Q_x)/4 \varepsilon - d
\end{array} \right]
\]

\[ \Lambda \text{ is positive definite when } (\theta - \theta^2) b + \theta g \geq \lambda(Q_x)/4 \varepsilon - d, \] which holds when (13) is satisfied. Finally, the claim follows by application of Lemma A.4 with \(a = \max\{1/2, \lambda(P_x)\}, \ a = \min\{1, \lambda(P_x)\}, \ c_3 = \frac{3}{2} \min\{2\rho_z, \lambda(Q_x)/4 \varepsilon \}\), and \(b_0 = \max\{2 \varepsilon \sup \|\hat{z}_v\|, \ v = 4\varepsilon \|P_x^{-1}E\| \sup \|\hat{w}_t\|\}. \]

**APPENDIX B**

**ANALYSIS OF PRIMAL-DUAL CONTROLLER**

In this section, we prove Proposition 4.2 and Theorem 4.3. We introduce the following change of variables for (20):

\[ \hat{x} := x - h(u, w), \quad h(u, w) := -A^{-1}Bu - A^{-1}Ew. \]

The dynamics (20) are rewritten in the new variables next.

**Lemma B.1:** Let Assumption 13 be satisfied, and for any \(t \in \mathbb{R}_0, \ (u, u, w) \) be the saddle-point of (17). The dynamics (20) have the following equivalent representation:

\[ \hat{z} := \hat{x} - h(u, w), \quad \hat{u} := -A^{-1}Bu - A^{-1}Ew. \]

The proof follows similar ideas as [16, Lemma 2]. By letting \(\varepsilon = 0\) in (47) we obtain \(A\hat{x} = 0\), which, by Assumption 1 implies \(\hat{x} = 0\). Hence, we let \(z := (u, \lambda) \) and \(\hat{z} := z - z^*, \) and we rewrite the dynamics (47) as \(\hat{z} = F_z(z - z^*) = F_z \hat{z}\), where

\[ F_z = \begin{bmatrix} F_{z_{21}} & F_{z_{22}} \\ F_{z_{23}} & 0 \end{bmatrix}. \quad (48) \]

We will prove that \(V(z) = \hat{z}^T P_z \hat{z} \) satisfies the assumptions of Lemma A.4. By the Schur Complement, \(P_z \) is positive definite if and only if \(\ell^T \eta_\nu I - G^T K^T K G > 0\). Using \(\eta_\nu > 4\varepsilon \eta_\nu, \ell \geq \mu \) and Assumption 8 one gets \(\ell^T \eta_\nu I - G^T K^T K G \geq (4\varepsilon) \eta_\nu I - kI \geq 3k > 0\), which shows that \(P_z \) is positive definite. By expanding the time-derivative:

\[ \frac{d}{dt} V(z) = \hat{z}^T (F_z P_z + P_z F_z) \hat{z} - 2 \hat{z}^T F_z \hat{z}_v, \quad (49) \]

Next, we show that \(\varepsilon \hat{z}_v^T F_z P_z + P_z F_z \hat{z} - 2 \hat{z}^T F_z \hat{z}_v \leq 0\), where \(\hat{z}_v = \min\{\hat{z}_v, \hat{z}_v^2\}\). Let \(M := F_z P_z + P_z F_z + \hat{z}_v P_z \). By expanding the product, \(M = [M_{ij}]\) is a 2x2 block symmetric matrix with blocks:

\[ M_{11} = 2\eta_{\ell y} (T_{u,t} + G^T T_{y,t} G) - 2\eta_{\ell y} G^T K^T K G - \beta_\varepsilon I, \]

\[ M_{12} = \eta_{\ell y} (T_{u,t} + G^T T_{y,t} G) G^T K^T - \beta_{\varepsilon} G^T K^T, \]

\[ M_{22} = 2\eta_{\ell y} G^T K^T G - \beta_{\varepsilon} \eta_\nu, \] and \(M_{21} = M_{12}^T\). By application of the Schur Complement, \(M \) is positive definite when \(M_{22} > 0\) and \(M_{11} - M_{12} M_{22}^{-1} M_{12}^T > 0\). The first condition can be rewritten as: \(M_{22} > 2(2\eta_{\ell y} k - k \beta_{\varepsilon} \eta_\nu I) > 0\), which we used Assumption 8 and the expression of \(\beta_{\varepsilon}\). For the second condition, we have:

\[ M_{12} M_{22}^{-1} M_{12} \leq 2\eta_{\ell y} G^T K^T G - 1 M_{12} \]

\[ = \eta_{\ell y} (T_{u,t} + G^T T_{y,t} G) G^T K^T + \frac{\beta_{\varepsilon} \eta_\nu}{\eta_\nu} - \beta_{\varepsilon} (T_{u,t} + G^T T_{y,t} G) G^T K^T + (T_{u,t} + G^T T_{y,t} G) \]

\[ \leq \eta_{\ell y} (T_{u,t} + G^T T_{y,t} G) + \frac{\beta_{\varepsilon} \eta_\nu}{\eta_\nu} - 2\beta_{\varepsilon} (T_{u,t} + G^T T_{y,t} G) \]
where the first bound follows from Assumption 5 and the definition of $\tilde{\rho}_\ell$, the second identity follows from $G^T K^T (K G^T K^T)^{-1} K G = I$, and the last bound follows from $G^T T_y \cdot I = 0$. Thus:

$$M_{11} - M_{12} M_2^{-1} M_{12}^T \geq 2\eta_u \ell (T_{u,t} + G^T T_y \cdot I) - 2\eta_\lambda G^T K^T K G$$

$$- \tilde{\rho}_\ell I - \eta_u \ell (T_{u,t} + G^T T_y \cdot I) - \tilde{\rho}_\ell I + 2\tilde{\rho}_\ell (T_{u,t} + G^T T_y \cdot I),$$

and, by using

$$\frac{1}{2} \eta_u \ell (T_{u,t} + G^T T_y \cdot I) - 2\eta_\lambda G^T K^T K G$$

$$\geq \left( \frac{1}{2} \eta_u \ell (\mu - 2\tilde{\eta}_k) I \right) > 0$$

$$\frac{1}{2} \eta_u \ell (T_{u,t} + G^T T_y \cdot I) - \rho I \geq \left( \frac{1}{2} \eta_u \ell (\mu - \rho I) I \right) \geq 0$$

$$\eta_u \ell (T_{u,t} + G^T T_y \cdot I) - \eta_u \ell (T_{u,t} + G^T T_y \cdot I) = 0,$$

we conclude $M_{11} - M_{12} M_2^{-1} M_{12}^T > 0$, which shows $M > 0$. As a result, (49) satisfies:

$$\frac{d}{dt} V(\tilde{x}) \leq -\tilde{\rho}_\ell V(\tilde{x}) + 2\|\tilde{z}\|\|P_2\| \|\tilde{z}\|^*_p$$

$$\leq -\tilde{\rho}_\ell \frac{2}{\tilde{\rho}_\ell} \frac{2}{\tilde{\rho}_\ell} (P_2) \|\tilde{z}\|^2 + 2\|\tilde{z}\|\|P_2\| \|\tilde{z}\|^*_p$$

$$\leq -\tilde{\rho}_\ell \frac{2}{\tilde{\rho}_\ell} \frac{2}{\tilde{\rho}_\ell} (P_2) \|\tilde{z}\|^2,$$

(51)

where the last inequality holds when $2\|\tilde{z}\|\|P_2\| \|\tilde{z}\|^*_p - \frac{\tilde{\rho}_\ell}{\tilde{\rho}_\ell} (P_2) \|\tilde{z}\|^2 \leq 0$, or $\|\tilde{z}\| \geq \frac{1}{\tilde{\rho}_\ell (P_2)} \|\tilde{z}\|^*_p$. Finally, the claim follows by application of Lemma 4.4 with $a = \lambda(P_2), b = \frac{2}{\tilde{\rho}_\ell}, b_0 = \frac{4}{\tilde{\rho}_\ell (P_2)} \|\tilde{z}\|^*_p$.

2) Proof of Theorem 3.3: Our proof technique leverages singular perturbation arguments inspired by [15, Ch. 11]. Let $z := (u, \lambda), \dot{z} = z - z^*$ and rewrite the dynamics (47) as:

$$\dot{x} = F_1 x + F_2 z + F_3 w_1, \quad \dot{z} = F_4 x + F_5 z,$$

(52)

where $F_1$ is defined by (48), $F_{11} := [F_{12}, F_{13}], F_{21} := [F_{21}, F_{23}]$. To show this claim, we will prove that the function $U(\tilde{x}, \tilde{z}) = (1 - \theta) V(\tilde{x}) + \theta W(\tilde{x})$, where $\theta = \|\sigma_1\|/\|\sigma_2\| + \|\sigma_1\|$ satisfies the assumptions of Lemma 4.4. By substituting (52) and by using $F_1 = F_2 = F_3 = F_4 = F_5 = 0$ (see (49) and (51)):

$$\dot{V}(\tilde{x}) = \tilde{x}^T (F_1^T P_1 + P_1 F_2) \tilde{x} + 2\tilde{x}^T \tilde{x} P_2 \tilde{x} - 2\tilde{z}^T P_2 \tilde{z}^*$$

$$\leq -\tilde{\rho}_\ell \tilde{z}^T \tilde{z}^* + \tilde{x}^T \sigma_1 \tilde{x} - 2\tilde{z}^T P_2 \tilde{z}^*$$

$$\leq -\frac{\tilde{\rho}_\ell}{\tilde{\rho}_\ell} \frac{2}{\tilde{\rho}_\ell} (P_2) \|\tilde{z}\|^2 + 2\|\tilde{z}\|\|P_2\| \|\tilde{z}\|^*_p$$

the last inequality holds when $\|\tilde{z}\| \geq \frac{1}{\tilde{\rho}_\ell (P_2)} \|\tilde{z}\|^*_p$. Next, by expanding the time-derivative of $W(\tilde{x})$:

$$W(\tilde{x}) = x^T (F_{11}^T P_x + P_x F_{11}) \tilde{x} + 2\tilde{x}^T P_x F_2 z + 2\tilde{x}^T P_x F_{14} w_1,$$

Using $F_{11} = A - \eta_u A^{-1} B G^T T_y \cdot C, A^T P_x + P_x A = -Q_x$:

$$\dot{x}^T (F_{11}^T P_x + P_x F_{11}) \tilde{x} = -\tilde{x}^T Q_x \tilde{x}$$

$$- \eta_u \varepsilon \tilde{x}^T (C^T T_y \cdot G B^T A^{-1} F_{12} + P_x A^{-1} B G^T T_y \cdot C) \tilde{x}.$$

Let $\Sigma_1 := 2P_x F_{11}, \Sigma_2 := 2\eta_u^{-1} P_x [F_{12}, F_{13}], \Sigma_3 := \eta_u (C^T T_y \cdot G B^T A^{-1} F_{12} + P_x A^{-1} B G^T T_y \cdot C)$, and $\Sigma_4 = P_x A^{-1} E$. Then,

$$\varepsilon \dot{W}(\tilde{x}) \leq -\frac{\lambda(Q_x)}{2} \|\tilde{z}\|^2 + \varepsilon \|\sigma_2\| \|\tilde{z}\|^2$$

+ $\varepsilon \|\Sigma_3\| \|\tilde{z}\|^2 + 2\|\Sigma_4\| \|\tilde{z}\| \|\tilde{w}_1\|$

$$- \frac{\lambda(Q_x)}{2} \|\tilde{z}\|^2 + \varepsilon \|\Sigma_3\| \|\tilde{z}\|^2 + \varepsilon \|\Sigma_4\| \|\tilde{z}\|^2,$$

where the last inequality holds if $-\frac{\lambda(Q_x)}{2} \|\tilde{z}\|^2 + 2\|\Sigma_4\| \|\tilde{z}\| \|\tilde{w}_1\| \leq 0$, or $\|\tilde{z}\| \geq \frac{\lambda(Q_x)}{2\|\Sigma_3\|} \|\tilde{w}_1\|$. By using $V(\tilde{x}) \leq \lambda(P_2) \|\tilde{z}\|^2$, by letting $\xi := (\|\tilde{z}\|, \|\tilde{w}_1\|)$, and by combining (51) and (52) we get

$$\dot{\Lambda} = -(1 - \theta) \rho \lambda(P_2) \frac{\lambda(P_2)}{(1 - \theta) \sigma_1 + \theta \sigma_2}$$

$$\frac{\lambda(P_2)}{(1 - \theta) \sigma_1 + \theta \sigma_2} - \theta \lambda(P_2) \frac{\lambda(P_2)}{(1 - \theta) \sigma_1 + \theta \sigma_2},$$

Matrix $\Lambda$ is positive definite when

$$\theta (1 - \theta) \lambda(P_2) \frac{\lambda(P_2)}{(1 - \theta) \sigma_1 + \theta \sigma_2} \|\tilde{z}\|^2 + \frac{\lambda(P_2)}{(1 - \theta) \sigma_1 + \theta \sigma_2} \|\tilde{w}_1\|^2 > 0,$$

which holds when the following is satisfied:

$$\varepsilon \leq \frac{\lambda(P_2)}{(1 - \theta) \sigma_1 + \theta \sigma_2} \|\tilde{z}\|^2 + \frac{\lambda(P_2)}{(1 - \theta) \sigma_1 + \theta \sigma_2} \|\tilde{w}_1\|^2.$$
