(Received 15 October, 2019; Accepted 19 December, 2019; Published online 6 March, 2020)

There is great interest in using natural supplements to treat various medical conditions. In this study, we evaluated the anti-oxidative and stem cell differentiation effects of a mixture of vitamin D, Lactobacillus rhamnosus, ginger, curcumin, and Boswellia extract. The calcein acetoxymethyl assay after H2O2 treatment showed that combined natural supplement had an anti-oxidative effect. NS-J also increased calcium deposition, as shown by Alizarin Red S staining, indicating bone formation activity. The contents of type II collagen and glycosaminoglycans, which are biomarkers of cartilage, were higher in mesenchymal stem cells treated with combined natural supplement than in cells treated with individual ingredients of the formula. In mesenchymal stem cells treated with human osteoarthritis synovial fluids, combined natural supplement enhanced the expression of type II collagen and PPAR-δ, overcoming the anti-chondrogenic effect of inflammatory conditions. Combined natural supplement also inhibited Oil Red O staining in cells, which indicates inhibited adipogenesis. Thus, combined natural supplement, a formula comprising vitamin D, Lactobacillus rhamnosus, ginger, curcumin and Boswellia extract, reduced oxidative stress, enhanced osteogenesis and chondrogenesis, and inhibited adipogenesis in mesenchymal stem cells to a greater extent than the individual ingredients, indicating synergistic interaction. In addition, combined natural supplement increased the expression PPAR-δ, suggesting that these effects correlate with the PPAR-δ pathway.

Key Words: natural ingredients, osteogenesis, adipogenesis, chondrogenesis

The use of natural supplements has a long history of treating multiple diseases.1 In our experience, these supplements have various effects such as pain reduction and anti-inflammation.1 Since natural supplements are complex mixtures, their net efficacy results from multiple interactions among the constituents.2,−4 Effects of natural dietary supplements have been published in various fields, such as their ability to improve in mitochondrial dysfunction.5 Interest in natural supplements is growing, and many relevant studies are ongoing around the world. Vitamin D is registered with the Food and Drug Administration (FDA) and has various positive effects on humans, such as improving knee cartilage integrity,6,7 suppressing arthritic inflammation,8 and increasing bone density.8 Lactobacillus rhamnosus (L. rhamnosus), also registered with the FDA, has been reported to improve arthritis9 and inflammation10,11 and reduce tissue damage,12 oxidative stress,13 and adiposity.14 Ginger has a strong ability to reduce the pain and other symptoms of arthritis.15 It also has anti-oxidative and anti-inflammatory effects.16 Curcumin has anti-arthritis17 and anti-inflammatory effects.18 Curcumin also enhances cartilage formation19 and muscle repair.20 Boswellia plant extract has anti-arthritic,21 analgesic,22 and anti-inflammatory effects.23 Thus, all those natural products have individually contributed significantly to the well-being of people.

Several papers have reported that those natural supplements show synergism.1,2,3 Jerzynska et al.5 reported that co-administration of vitamin D supplements and Lactobacillus rhamnosus showed better immunological response than individual administration in pediatric allergy rhinitis patients. These natural supplements show similar properties, but combining them can generate additive or synergistic effects on the human body. However, research on the mechanisms of natural supplements remain inadequate. Also, further research is needed on how natural supplements or supplement combinations influence stem cells.

Peroxisome proliferator–activated receptors (PPARs) are members of the nuclear hormone receptor superfamily and play an important role in glucose and fat metabolism.24 PPAR-δ is expressed ubiquitously and involved in apoptosis, fat metabolism and chondrogenesis.25 Heck et al.26 reported that a PPAR-δ selective agonist (GW0742) had enough chondrogenic effect to overcome the anti-chondrogenic effect of inflammation. The previously mentioned natural supplements are all anti-inflammatory and pro-chondrogenic. A comparative study of a mixture of vitamin D, L. rhamnosus, ginger, curcumin, and Boswellia extract (NS-J) and PPAR-δ is thus a useful way to investigate the mechanism of those natural supplements.

For this study, we investigated how the combination of these natural ingredients would affect mesenchymal stem cells (MSCs) in terms of resistance to oxidative stress and differentiation potential. We also demonstrate a correlation between PPAR-δ and NS-J.

Methods

Isolation and culture of hBM-MSCs. Frozen mononuclear cells from human bone marrow were purchased (AllCells,

©2020 JCBN

doi: 10.3164/jcbn.19-97

J. Clin. Biochem. Nutr. | May 2020 | vol. 66 | no. 3 | 206–212
Emeryville, CA) and used to isolate human bone marrow-derived mesenchymal stem cells (hBM-MSCs). Briefly, thawed mononuclear cells were cultured in Dulbecco’s modified Eagle medium (DMEM) plus 20% fetal bovine serum (FBS) and 1% antibiotic-antimycotic solution (Invitrogen, Carlsbad, CA) and plated at a density of 1 × 10^6 cells/75-cm² flask. Adherent cells were re-plated at a density of 1–5 × 10^6 cells per 75-cm² flask and cultured at 37°C in a 5% CO₂ incubator. The culture medium was exchanged with fresh medium after 48 h and then every 3–4 days until the cells were 70% confluent.

**Extract preparation and NS-J.** Vitamin D, L. *rhannmosus*, ginger, curcumin and Boswellia extract powder were supplied by Pure Source, LLC (Doral, FL). Dried samples were blended to a fine powder and extracted three times (30 min each with continuous stirring at 60°C) with dimethyl sulfoxide (DMSO). The filtrates were combined and concentrated using a rotary evaporator. The collected samples were kept in amber colored screw capped bottles at −18°C until analysis. Stock solutions in DMSO were prepared at concentrations of 50 mg/ml. Formula NS-J contained vitamin D3, L. *rhannmosus*, ginger root extract, curcumin from turmeric root extract and Boswellia serrata extract. The concentration of NS-J is 50 μg/ml and the ratio of each natural ingredients are 1:2:9:64:91.

**Hydrogen peroxide treatment to induce oxidative stress.** hBM-MSCs (passages 2–3) were re-plated on a six-well plate and incubated in DMEM plus 10% FBS and 1% antibiotic-antimycotic solution for 1 day. Then, the hBM-MSCs were treated with 50 μg/ml of vitamin D, L. *rhannmosus*, ginger, curcumin, Boswellia extract, or NS-J. hBM-MSCs (passage 6) were seeded in the wells of 24-well plates at a density of 1 × 10^5 cells/cm² and treated with 100 μM H₂O₂. hBM-MSCs were incubated in 1 × PBS containing 2 μM calcein acetoxymethyl ester (calcein-AM, live cells: green) and 4 μM ethidium homodimer-1 (dead cells: red) for 10 min at 37°C. Immediately thereafter, the cells were imaged under the 10× objective of a fluorescence Olympus IX71 microscope (Olympus America Inc., Center Valley, PA). Five thousand cells per treatment were analyzed for viability using Metamorph (Olympus America Inc., Center Valley, PA). The optical density of the sample was measured at 405 nm using a microplate reader.

**Osteogenic differentiation of human hBM-MSCs.** hBM-MSCs (passages 2–3) were re-plated in a 75-cm² flask at a density of 1 × 10^5 cells/cm² and cultured in the alpha modification of minimum essential medium (α-MEM) with 20% FBS at 37°C for 1 day. The next day, the medium was switched to Stem X-Vivo medium (R&D System, Minneapolis, MN). MSCs were cultured in osteogenic medium with and without 50 μg/ml of vitamin D, L. *rhannmosus*, ginger, curcumin, Boswellia extract, or NS-J. The medium was replaced every other day for 21 days. To assess calcium deposition, the cells were washed with ice-cold PBS and incubated in 10% paraformaldehyde for 10 min. Then, the cells were incubated in 2% Alizarin Red S (Sigma, St. Louis, MO), which stains calcium in cells, at pH 4.2 for 10 min and washed three times with distilled water. The stained cells were visualized by phase-contrast microscopy to determine cell morphology and verify the presence of mineralized nodules (red) after image acquisition. For quantification, an Osteogenesis Quantitation Kit (Millipore, Billerica, MA) was used following the manufacturer’s recommendation. Briefly, 400 μl of 10% acetic acid was added to each well of a 24-well plate. Cells were incubated for 30 min on a shaker, gently scraped off the plate, and transferred to a 1.5-ml microtube. After vigorous vortexing for 30 s, the samples were heated to 85°C for 10 min and incubated on ice for 5 min. After centrifugation at 20,000 × g for 15 min, the supernatant was transferred to a new 1.5-ml microtube. The acidic pH of the sample was neutralized with ammonium hydroxide. The optical density of the sample was measured at 405 nm using a microplate reader.

**Chondrogenic differentiation of human hBM-MSCs.** Chondrogenic differentiation was assessed by high-density micromass culturing on hyaluronic acid (HA) gel (Euflexxa®; Ferring Pharmaceuticals Inc., Parsippany, NJ). hBM-MSCs (passages 2–3) were plated in a 75-cm² flask at a density of 1.5 × 10^5 cells/cm² and cultured in α-MEM with 20% FBS for 1 day at 37°C. The next day, the hBM-MSCs were harvested and re-plated on 70 μl of HA gel (Euflexxa®) at a density of 8 × 10^4 viable cells/well in a 96-well plate. Then, 50 μl of chondrogenesis medium (STEMPRO® Chondrogenesis Differentiation Kit, Life Technologies, Grand Island, NY) was added to each well with and without vitamin D, L. *rhannmosus*, ginger, curcumin, Boswellia extract, or NS-J. After chondrocyte spheroids formed, the culture medium was replaced with fresh chondrogenesis medium every 2 days for the next 14-days of incubation for chondrogenesis.

**Chondrogenic differentiation of human MSCs with human OA synovial fluids.** Human osteoarthritis (OA) synovial fluid was used to assess the effects of inflammation. hBM-MSCs (passages 2–3) were incubated in chondrogenic medium with and without HA, NS-J and 50% human OA synovial fluid for 14 days. By the 14th day, chondrocyte spheroids had formed, and images of them were captured using a light microscope.

Then, the chondrocytes were processed for immunoblotting using antibodies to type II collagen (1:1,000 dilution; EMD Millipore, Billerica, MA), PPAR-δ (1:2,000 dilution; Abcam, Cambridge, MA) and β-actin as a loading control (1:10,000 dilution; Abcam). Secondary antibodies tagged with horseradish peroxidase (mouse for type II collagen and β-actin, 1:5,000 dilution) were used. The proteins were separated by polyacrylamide gel electrophoresis and then transferred to nitrocellulose membranes (GE Healthcare Life Sciences, Pittsburgh, PA) using a TE77XP semi-dry blotter operated at 10 V for 3 h ( Hoefer, Inc., Holliston, MA). Protein band signals on the blots were detected using Amersham Hyperfilm with enhanced chemiluminescence sensitivity (GE Healthcare Life Sciences) and a SuperSignal West Pico Chemiluminescent substrate kit (Thermo Fisher Scientific, Rockford, IL).

The use of human synovial fluid was approved by the Institutional Review Board of University of Toledo. Discarded synovial fluids were obtained after receiving informed consent from patients.

**Adipogenic differentiation of human MSCs.** hBM-MSCs (passages 2–3) were incubated in adipogenic medium (DMEM containing high glucose, 4.5 g/L; Invitrogen), 10 μg/ml insulin, 60 μM indomethacin, 10% FBS, and antibiotic-antimycotic (Invitrogen) and treated with 50 μg/ml NS-J every second day for 14 days. On the 14th day, the cells were stained with Oil Red O, which stains lipid droplets, and imaged using a light microscope. Lipid droplets were eluted by adding 100 μl of isopropanol to each well. The absorbance of the elute was measured at 490 nm using a microplate reader to evaluate adipogenesis.

**Results**

**NS-J protects hBM-MSCs from oxidative stress.** We performed a live/dead cell analysis using calcein AM (live cells: green) and ethidium homodimer-1 (dead cells: red). Most untreated MSCs underwent apoptosis after a 12-h exposure to H₂O₂ (Fig. 1A). MSCs treated with ginger and curcumin were protected against oxidative stress. Conversely, those treated with vitamin D and Boswellia extract did not show any difference in survival from control cells. We then tested whether the combination of vitamin D, L. *rhannmosus*, ginger, curcumin, and Boswellia extract protected MSCs from oxidative stress. The combination significantly increased the percentage of surviving MSCs by 10-fold compared with the control (Fig. 1B). This result suggests that natural supplements, especially ginger and curcumin protect MSCs from oxidative stress, and that the individual components of NS-J interacted synergistically to protect human MSCs from oxidative stress.
NS-J enhances the osteogenesis of hBM-MSCs. We next examined the effects of the natural supplements and the combined formula (NS-J) on osteogenic differentiation of hBM-MSCs. Using calcium deposition in formed osteoblasts, Alizarin Red S-stained cells were visualized by phase-contrast microscopy to determine cell morphology and verify the presence of red mineralized nodules. The hBM-MSCs treated with individual natural ingredients did not form more osteoblasts than the control cells (Fig. 2A). By contrast, treatment with the combination formula drastically increased the formation of osteoblasts compared with treatment with individual components of the formula (Fig. 2B). These results indicate that synergism among the ingredients of NS-J amplifies the osteogenic effects of the individual ingredients.

NS-J enhances the chondrogenesis of hBM-MSCs. Through chondrogenic differentiation, MSCs start to aggregate and condense, forming chondrocyte spheroids in vitro (Fig. 3A). Thus, we examined the effects of the natural ingredients and NS-J on chondrogenesis of hBM-MSCs by measuring chondrocyte spheroids. hBM-MSCs treated with Boswellia extract formed a few small spheroids. Cells treated with ginger, curcumin, or vitamin D formed larger chondrocyte spheroids and a few round spheroids. Cells treated with L. rhamnosus formed a great number of large spheroids than the control cells, and those spheroids produced a noticeable amount of glycosaminoglycans (GAGs). Cells treated with NS-J formed larger chondrocyte spheroids and generated a substantial number of surrounding GAGs. These results suggest that NS-J has a strong chondrogenic effect on human MSCs. We next quantified the amount of type II collagen, the major constituent of functional joint cartilage in chondrocytes, after treating cells with individual natural ingredients and NS-J. Compared with the control treatment and treatment with individual natural products, treatment with NS-J significantly increased the production of type II collagen (Fig. 3B and C). These results demonstrate that vitamin D and L. rhamnosus have chondrogenic effects and that NS-J enhanced functional chondrogenesis in hBM-MSCs in a synergistic manner.

NS-J enhances chondrogenic differentiation under inflammatory conditions and increases the expression of PPAR-δ. We next examined whether the chondrogenic effects of NS-J were maintained under inflammatory conditions. hBM-MSCs (passages 2–3) were incubated in chondrogenic medium with and without HA, NS-J and 50% human OA synovial fluid for 14 days. Under inflammatory conditions (presence of OA synovial fluid), chondrocyte spheroids were smaller than those formed in the absence of OA synovial fluid. Under inflammatory conditions (presence of OA synovial fluid), chondrocyte spheroids were smaller than those formed in the absence of OA synovial fluid. However, NS-J significantly increased the size of chondrocyte spheroids even in the presence of OA synovial fluid with no difference in size of chondrocyte

Fig. 1. Human MSCs were plated in a 24-well plate and 100 μM H_{2}O_{2} was added to the cells followed by a 12-h incubation. Cell survival was measured by calcein AM staining. The concentration of all ingredients was 50 μg/ml. *p<0.05 vs Control, †p<0.001 vs NS-J. Scale bar = 100 μm. See color figure in the on-line version.
spheroids compared with the non-inflammatory control condition. HA had no significant effect on size of spheroids under inflammatory conditions (Fig. 3D). This result indicates that the anti-inflammatory effect of NS-J overwhelmed the anti-chondrogenic effect of inflammation.

NS-J showed properties similar to those of a PPAR-δ agonist (GW0742), including anti-inflammatory, pro-chondrogenic, and anti-adipogenic effects. We therefore used immunoblotting to examine the expression of type II collagen and PPAR-δ in response to NS-J treatment. Inflammatory conditions decreased the expression of type II collagen and PPAR-δ whereas NS-J increased this expression under inflammatory conditions. HA had no significant effect on protein expression (Fig. 3D–G). These results demonstrate that the properties of NS-J correlate with the PPAR-δ pathway, and that NS-J has an anti-inflammatory effect. This is the first time that this natural supplement complex has been reported to affect the expression of PPAR-δ.

NS-J decreases the adipogenesis of hBM-MSCs. To examine the effects of NS-J and its component ingredients on MSC adipogenesis, hBM-MSCs were incubated in adipogenic medium with or without 50 μg/ml of NS-J for 14 days and then stained with Oil Red O, which stains lipid droplets. Images of lipid droplet-containing adipocytes that had differentiated from hBM-MSCs were captured under a light microscope. The extent of adipogenesis (accumulation of red lipid droplets) was measured using a microplate reader (absorbance at 490 nm). NS-J significantly reduced adipogenesis of hBM-MSCs (Fig. 4A and B).

Discussion

Oxidative stress causes degeneration and apoptosis of cells including MSCs, in various organ tissues, thereby contributing to inflammatory, metabolic, and degenerative diseases. We examined whether the combination of several natural products could protect hBM-MSCs from oxidative stress caused by H$_2$O$_2$. Although some individual components of the formula offered some protection, the combination of vitamin D, L. rhamnosus, ginger, curcumin, and Boswellia extract (NS-J) greatly enhanced the survival rate of human MSCs exposed to oxidative stress. The antioxidant properties of the individual components appeared to contribute slightly to protection, but the extent of protection was greater than an additive effect. This combination shows synergism on the antioxidant effect.

Further experiments revealed that NS-J also had synergistic effects on human MSCs in terms of decreased adipogenesis and enhanced osteogenesis, and chondrogenesis. L. rhamnosus by itself had a considerable anti-adipogenic effect, but NS-J reduced MSC adipogenesis even further. The anti-adipogenic effects of
Fig. 3. (A) Human MSCs were cultured in 70 μl of clinical hyaluronic acid (HA) gel during chondrogenesis in 96-well plates. (B) Human MSCs were cultured in 70 μl of Euflexxa® during chondrogenesis in 96-well plates. Relative levels of type II collagen and β-actin (C) were quantified by immunoblotting and results are presented in bar graphs. MSCs were incubated in chondrogenic media. Chondrocyte hyaline was measured by assessing expression of type II collagen. (D) Human MSCs were cultured with 50% human osteoarthritis synovial fluid for 14 days to compare chondrogenic effect of natural supplement under inflammatory condition. (E–G) The expression of type II collagen and PPAR-δ were quantified by immunoblotting. *p<0.05 vs Control, †p<0.001 vs NS-J, ‡p<0.05 vs SF. Scale bar = 100 μm. See color figure in the on-line version.
the individual components likely contributed to the synergistic anti-adipogenic effect of NS-J, but most of the anti-adipogenic effect, was likely contributed by L. rhamnosus, consistent with the finding of a previous study.\textsuperscript{(14)} The anti-adipogenic effect of NS-J on human MSCs is a new finding of this study.

NS-J had significant synergistic effects in osteogenesis. Chondrogenesis was also enhanced by NS-J. NS-J treatment generated the most noticeable extracellular matrix around chondrocyte spheroids and a larger amount of type II collagen than the other treatments tested. Vitamin D and L. rhamnosus had significant chondrogenic effects, and ginger, curcumin and Boswellia extract each had a significant osteogenic effect. Ginger and curcumin had a significant anti-oxidative effect. The combination of these natural supplements produced synergistic interactions among the individual components.

Oxidation regulates the pathway of osteogenesis, chondrogenesis and adipogenesis.\textsuperscript{(27)} Reactive oxygen species (ROS) are essential in the early stage of chondrogenic differentiation.\textsuperscript{(28)} Chen et al.\textsuperscript{(29)} reported that ROS inhibit osteogenic differentiation of MSCs. Those studies support our finding that the anti-oxidative effect of NS-J affects the osteogenesis, chondrogenesis and adipogenesis of MSCs. Synergism in the anti-oxidative effect also affects the synergism of NS-J’s other properties.

A previous study reported that a mixture of a PPAR-\(\delta\) agonist (GW0742), MSCs and HA (CHAMP) had anti-inflammatory, pro-chondrogenic and anti-adipogenic effects.\textsuperscript{(22)} The properties reported for the PPAR-\(\delta\) agonist mixture were similar to those we observed for NS-J. We therefore demonstrated a correlation between PPAR-\(\delta\) and NS-J. The data which shows that NS-J increased the expression of PPAR-\(\delta\), suggest that the anti-inflammatory, anti-adipogenic and pro-chondrogenic effects of NS-J are mediated through the PPAR-\(\delta\) pathway. This hypothesis could explain the medical effects of this combination of natural supplements. A solid understanding of the mechanism of natural supplements could be used to reinforce their medical effects and inhibit side effects.

Most of the individual components of NS-J have anti-arthritic effects as well as analgesic and anti-inflammatory effects.\textsuperscript{(7,9,15,17,22)} and the combined formula is ideal for treating joint arthritis as well as osteoarthritis because NS-J enhances chondrogenesis and reduces pain and inflammation. Several studies report that combinations of phytomedicines have synergistic effects.\textsuperscript{(30,31)} NS-J demonstrated synergistic benefits that could help treat arthritis. Because the pharmacokinetics of each component are likely different, their synergistic effects could vary in different tissues, which remains to be explored in future studies.

A limitation of our study is that although the anti-inflammatory and analgesic effects of the individual components of NS-J have been studied,\textsuperscript{(28,15,17,22)} the synergistic interactions among them have not yet been analyzed. In addition, further research is required to determine the molecular mechanisms by which the combination of ingredients can be anti-oxidative, osteogenic, chondrogenic and anti-adipogenic effects. Additional molecular mechanism studies are also needed to explain the synergistic effect.

In summary, we demonstrated that NS-J promotes differentiation of MSCs into osteoblasts or chondrocytes to a greater extent than its individual ingredients, indicating synergistic interactions among those ingredients. In addition, NS-J protected MSCs from oxidative stress. These effects of NS-J likely occur through stimulation of the PPAR-\(\delta\) signaling pathway. The chondrogenic effects of NS-J could promote healthy cartilage and reduce the pain and symptoms of osteoarthritis.
