Abstract

Magnetic fields and mechanical forces can change the deformation and stability of magnetic emergent crystals (MECs) such as Bloch skyrmion crystal (SkX), Néel SkX and Anti-SkX. Due to the tensor nature of strains, mechanical loads provide more fruitful ways to manipulate the MECs, while their effect on MECs other than the Bloch SkX is hitherto unclear. We construct a thermodynamic model for noncentrosymmetric ferromagnets in all possible point groups when subjected to coupled magnetoelastic fields. Compared with classic theories, we include terms coupling the elastic strains, the magnetization, and its derivatives in the free energy, which lead to strain-induced Dzyaloshinskii–Moriya interaction anisotropy. For epitaxial thin films in three types of point groups (T, C3v, D2d) hosting Bloch SkX, Néel SkX and Anti-SkX, we find the newly added terms always deform the MECs and eventually lead to their instability as the misfit strains increase. Specifically, for Bloch SkX in group T materials and Néel SkX in group C3v materials, a novel magnetic phase called paired-skyrmion crystal (pSkX) appears. Our theory lays the path to study deformation and phase transitions of different MECs, and to explore novel states of MECs in chiral magnets when subjected to magnetoelastic fields.

1. Introduction

Magnetic emergent crystals (MECs) are spatially periodic field patterns of magnetization that emerge from the atomic crystals. Examples of MECs include the Bloch skyrmion crystal (SkX), Néel SkX and Anti-SkX. Due to the tensor nature of strains, mechanical loads provide more fruitful ways to manipulate the MECs, while their effect on MECs other than the Bloch SkX is hitherto unclear. We construct a thermodynamic model for noncentrosymmetric ferromagnets in all possible point groups when subjected to coupled magnetoelastic fields. Compared with classic theories, we include terms coupling the elastic strains, the magnetization, and its derivatives in the free energy, which lead to strain-induced Dzyaloshinskii–Moriya interaction anisotropy. For epitaxial thin films in three types of point groups (T, C3v, D2d) hosting Bloch SkX, Néel SkX and Anti-SkX, we find the newly added terms always deform the MECs and eventually lead to their instability as the misfit strains increase. Specifically, for Bloch SkX in group T materials and Néel SkX in group C3v materials, a novel magnetic phase called paired-skyrmion crystal (pSkX) appears. Our theory lays the path to study deformation and phase transitions of different MECs, and to explore novel states of MECs in chiral magnets when subjected to magnetoelastic fields.
of elastic constants of the materials [28, 29] when subjected to mechanical forces [30]. In the model constructed, it is shown that classic theories of magnetoelastic coupling in ferromagnets [31, 32] are not sufficient to explain the above mentioned phenomena, and terms of the form $\varepsilon_{ij}M_iM_j$ must be added to the Helmholtz free energy density. Interestingly, when studying the deformation of SkX in MnSi [21, 30], it is found that the scale of the energy term $\varepsilon_{ij}M_iM_j$ is at least an order of magnitude smaller than that of the regular magnetoelastic term $\varepsilon_{ij}M_i^2$, while the two terms are both indispensable. This recalls us of the fact that SkX in bulk helimagnets are stabilized by competition between the exchange interaction and the Dzyaloshinskii–Moriya interaction (DMI), where DMI is usually of a much smaller scale than that of the exchange interaction. In fact, the term $\varepsilon_{ij}M_iM_j$ can be interpreted as strain-induced DMI anisotropy, which generally exists for all chiral magnets, while their precise form for materials outside group $T$ is not known. Besides, the free energy functional derived for B20 compounds is the Helmholtz free energy, which is applicable when the system is subjected to strain restrictions. When mechanical forces are applied at the boundary, the appropriate thermodynamic potential, being the elastic Gibbs energy [33], is not obtained.

In this paper, we systematically develop the thermodynamics of chiral magnets under coupled magnetoelastic fields. Specifically, we accomplish the following points: (A) for chiral magnets in different point groups, we derive the concrete form of magnetoelastic free energy density functional incorporating the strain-induced DMI anisotropy through symmetry analysis; (B) through Legendre transformation, we derive the general expression of the elastic Gibbs energy for chiral magnets; (C) for chiral magnets in three specific point groups ($T, C_{4v}, D_{2d}$), we derive the thermodynamic potential for their epitaxial thin films when subjected to equiaxed in-plane misfit strain or pure shearing misfit strains. We systematically analyze the effect of the strain-induced DMI anisotropy on the deformation and stability of the three types of MECs (Bloch SkX, Néel SkX, Anti-SkX) that appear in the materials. Generally speaking, presence of the strain-induced DMI anisotropy term in the magnetoelastic free energy profoundly affects the deformation of the MECs such that they are stretched, sheared, or rotated in certain direction when subjected to a combination of magnetic fields and misfit strains. In particular, at appropriate conditions, a novel magnetic state called paired-skyrmion crystal (pSkX) may appear in thin films in group $T$ and group $C_{4v}$. pSkX is also topologically nontrivial, but possesses a different topological density than the SkX phase. This means that as the value of misfit strains smoothly changes, a phase transition between two topologically nontrivial states occurs, accompanied by a jump of topological density. To sum up, we establish the theoretical foundation for studying magnetoelastic related phenomena in different skyrmionic magnetic materials.

### 2. Helmholtz free energy density with magnetoelastic interactions for chiral magnets

Generally, the Helmholtz free energy density with magnetoelastic interactions for chiral magnets takes the following form:

$$w = w_{\text{mag}}(\mathbf{m}) + w_{\text{me}}(\mathbf{m}, \varepsilon_{ij}) + w_{\text{el}}(\varepsilon_{ij}),$$

where $w_{\text{mag}}(\mathbf{m})$ denotes the part of free energy density which relies merely on the magnetization vector $\mathbf{m}$, $w_{\text{me}}(\mathbf{m}, \varepsilon_{ij})$ denotes the contribution of magnetoelastic coupling, and $w_{\text{el}}(\varepsilon_{ij})$ denotes the elastic energy density which relies merely on the strain components $\varepsilon_{ij}$. We present here two available models of $w_{\text{mag}}(\mathbf{m})$ that are widely used. The first model is temperature dependent, which yields a magnetization vector with changeable modulus:

$$w_{\text{mag}}(\mathbf{m}) = w_{\text{DM}}(\mathbf{m}) + \sum_{i=1}^{3} \left( \frac{\partial m_i}{\partial r_i} \right)^2 - 2b \cdot \mathbf{m} + t\mathbf{m}^2 + \mathbf{m}^4,$$

where $w_{\text{DM}}(\mathbf{m})$ denotes the generalized DMI whose exact form depends on the symmetry of the material (expanded in supplementary material [https://stacks.iop.org/NJP/23/023016/mmedia] part A), $t$ denotes the temperature, and $b$ denotes the magnetic field. This model derives from the Landau theory [32], which is usually used near the Curie temperature to study temperature dependent phenomena. The second model is used at low temperature, which yields a magnetization vector with fixed modulus:

$$w_{\text{mag}}(\mathbf{m}) = w_{\text{DM}}(\mathbf{m}) + \sum_{i=1}^{3} \left( \frac{\partial m_i}{\partial r_i} \right)^2 - b \cdot \mathbf{m}.$$

Equations (2) and (3) are presented in a rescaled manner for convenience, with two types of different rescaling procedure (for equation (2), see the supplementary information of reference [1], for equation (3), see reference [34]).
For chiral magnets, we propose a general form of $w_{\text{me}}(\mathbf{m}, \varepsilon_{ij})$ as follows:

$$w_{\text{me}}(\mathbf{m}, \varepsilon_{ij}) = a_{ijkl}\varepsilon_{ij}m_km_l + d_{ijklm}e_{ij}m_km_lm_m,$$

(4)

where the first term with coefficient $a_{ijkl}$ (hereafter called the $a$ term) is the interaction considered in classic theories of magnetoelastic coupling [31, 32]. When studying the effect of strains in chiral magnets, the second term with coefficient $d_{ijklm}$ (hereafter called the $d$ term) is non-ignorable, and sometimes dominant. If one fixes the strains of the material, the $d$ term induces an anisotropy to the DMI, which can be significant due to the intrinsic smallness of the DMI. The form of magnetoelastic free energy density given in equation (4) can be simplified after considering the symmetry requirement of the materials, which reduces to

$$w_{\text{me}}(\mathbf{m}, \varepsilon_{ij}) = \sum_{i=1}^{n_{GL}} K_{Gij}(\varepsilon_{ij}, \mathbf{m}) + \sum_{i=1}^{n_{GL}} L_{Gij}(\varepsilon_{ij}, \mathbf{m}, \nabla \mathbf{m}),$$

(5)

where the first term with coefficient $K_{Gij}$ is reduced from the $a$ term, and the second term with coefficient $L_{Gij}$ is reduced from the $d$ term, and the subscript $G$ depends on the point group of the material considered (e.g. for group $O$, the letter $G$ is replaced by $O$). For a specific point group, $n_{GL}$ determines the independent thermodynamic parameters we have in the model. The detailed expression of $f_{Gij}(\varepsilon_{ij}, \mathbf{m})$ and $L_{Gij}(\varepsilon_{ij}, \mathbf{m}, \nabla \mathbf{m})$ are given in supplementary material part B. When the material studied is suffering homogeneous deformation, the number $n_{GL}$ can be further reduced to $n'_{GL}$, because some pairs of the expressions of $f_{Gij}(\varepsilon_{ij}, \mathbf{m}, \nabla \mathbf{m})$ are found to be equivalent to each other through integration by part. The values of $n_{GL}$, $n_{GL}$, and $n'_{GL}$ are listed in table 1 for different groups.

To make use of the model proposed in equation (1), one has to obtain the exact values of the thermodynamic parameters, especially the magnetoelastic parameters $a_{ijkl}$ and $d_{ijklm}$ proposed in equation (4). These parameters can generally be determined through magnetostriction measurements. Here, we use group $O$ as an example to show how to determine these thermodynamic parameters by experiments or first-principle calculation of the magnetostriiction. For materials in group $O$, we have

$$w_{\text{me}}(\mathbf{m}, \varepsilon_{ij}) = \sum_{i=1}^{3} K_{Gij}(\varepsilon_{ij}, \mathbf{m}) + \sum_{i=1}^{6} L_{Gij}(\varepsilon_{ij}, \mathbf{m}, \nabla \mathbf{m}),$$

(6)

where

$$f_{Gij} = e_{11}m_1^2 + e_{22}m_2^2 + e_{33}m_3^2,$$

(7a)

$$f_{Gij} = e_{11}m_1^2 + e_{12}m_1m_2 + e_{13}m_1m_3 + e_{22}m_2^2 + e_{33}m_3^2 + e_{33}m_3^2 + e_{33}m_3^2 + e_{33}m_3^2,$$

(7b)

$$f_{Gij} = 4e_{12}m_1m_2 + 4e_{13}m_1m_3 + 4e_{23}m_2m_3,$$

(7c)

$$f_{Gij} = e_{11}m_1m_2 - e_{12}m_1m_3 - e_{22}m_2m_3 + e_{11}m_1m_2 + e_{22}m_2m_3 + e_{33}m_3^2 - e_{33}m_3^2 - e_{33}m_3^2 - e_{33}m_3^2,$$

(7d)

$$f_{Gij} = e_{11}m_1m_2 - e_{12}m_1m_3 - e_{22}m_2m_3 + e_{33}m_3^2 - e_{33}m_3^2 - e_{33}m_3^2 - e_{33}m_3^2,$$

(7e)

$$f_{Gij} = e_{11}m_1m_2 + e_{22}m_1m_3 + e_{33}m_3^2 - e_{22}m_2m_3 + e_{33}m_3^2 - e_{33}m_3^2 - e_{33}m_3^2,$$

(7f)

$$f_{Gij} = 2e_{12}m_1m_1 - 2e_{12}m_2m_2 + 2e_{13}m_1m_3 + 2e_{13}m_2m_3 - 2e_{13}m_2m_3 + 2e_{13}m_2m_3 - 2e_{13}m_2m_3,$$

(7g)

$$f_{Gij} = 2e_{12}m_1m_1 - 2e_{12}m_2m_2 + 2e_{13}m_1m_3 + 2e_{13}m_2m_3 + 2e_{13}m_2m_3 - 2e_{13}m_2m_3,$$

(7h)

$$f_{Gij} = 2e_{12}m_1m_1 - 2e_{12}m_2m_2 + 2e_{13}m_1m_3 + 2e_{13}m_2m_3 + 2e_{13}m_2m_3 - 2e_{13}m_2m_3,$$

(7i)
When the material studied is free from external forces, we have for the stresses \( \sigma_{ij} = \frac{\partial w_{el}}{\partial \gamma_{ij}} = 0 \) for \( i = j \) and \( \sigma_{ij} = \frac{\partial (w_{ex} + w_{el})}{\partial \gamma_{ij}} = 0 \) for \( i \neq j \) (\( \gamma_{ij} = 2 \varepsilon_{ij} \)), where \( w_{el} = \frac{1}{2} C_{ij} (\varepsilon_{11}^2 + \varepsilon_{22}^2 + \varepsilon_{33}^2) + 2 C_{44} (\varepsilon_{23}^2 + \varepsilon_{13}^2 + \varepsilon_{12}^2) + C_{12} (\varepsilon_{11} \varepsilon_{22} + \varepsilon_{11} \varepsilon_{33} + \varepsilon_{22} \varepsilon_{33}) \). For materials in group 0 it gives:

\[
\begin{align*}
C_{11} \varepsilon_{11} + C_{12} (\varepsilon_{22} + \varepsilon_{33}) &= -\partial_{m} (m, \nabla m), \\
C_{11} \varepsilon_{22} + C_{12} (\varepsilon_{11} + \varepsilon_{33}) &= -\partial_{m} (m, \nabla m), \\
C_{11} \varepsilon_{33} + C_{12} (\varepsilon_{11} + \varepsilon_{22}) &= -\partial_{m} (m, \nabla m),
\end{align*}
\]

(8)

where \( C_{ij} \) are the elastic stiffness of the material, and \( \partial_{m} = K_{01} m_{1}^2 + K_{02} (m_{2}^2 + m_{3}^2) + (L_{01} - L_{02}) \) (\( m_{2} \) is treated as a single parameter because when suffering magnetostriction (in equation (11), \( C_{ij} \) and \( m_{i} \) are the so-called magnetostriction coefficient and magnetization. For the measured strains \( \varepsilon_{ij} \), we have after manipulation

\[
\begin{align*}
K_{01} &= -\frac{1}{m_{1}^2} \left[ C_{11} \varepsilon_{33} + C_{12} (\varepsilon_{11} + \varepsilon_{22}) \right], \\
K_{02} &= -\frac{1}{m_{1}^2} \left[ C_{11} \varepsilon_{11} + C_{12} (\varepsilon_{11} + \varepsilon_{22}) \right].
\end{align*}
\]

(9) (10)

Equations (9) and (10) determines \( K_{01} \) and \( K_{02} \) by the measured strains and magnetization. At a lower magnetic field, the material is stabilized in the conical phase with the magnetization \( m = [m_{q} \cos(qr_{3})m_{0}] \), where \( m_{q} \) denotes the Fourier magnitude, \( m_{0} \) denotes the constant \( r_{3} \)-component, and \( q \) denotes the wave number. We have after manipulation

\[
L_{01} - L_{02} = -\frac{2}{m_{q}^2} \left[ C_{11} \varepsilon_{11} + C_{12} (\varepsilon_{11} + \varepsilon_{22}) + \frac{1}{2} (K_{01} + K_{02}) m_{q}^2 + K_{02} m_{0}^2 \right],
\]

(11)

\[
L_{01} - L_{02} = -\frac{1}{m_{q}^2} \left[ C_{11} \varepsilon_{33} + C_{12} (\varepsilon_{11} + \varepsilon_{22}) + K_{01} m_{q}^2 + K_{02} m_{0}^2 \right].
\]

(12)

Similarly, apply a strong magnetic field and a moderate magnetic field in direction [110], the magnetization is given respectively by \( m = [\sqrt{2}/2m_{q}, \sqrt{2}/2m_{q}, 0] \) and

\[
\begin{align*}
m &= \left[ \begin{array}{c}
\sqrt{2}/2(m_{q} \cos(\sqrt{2}/2q(r_{1} + r_{2})) + m_{0}) \\
\sqrt{2}/2(-m_{q} \cos(\sqrt{2}/2q(r_{1} + r_{2})) + m_{0}) \\
m_{q} \sin(\sqrt{2}/2q(r_{1} + r_{2})).
\end{array} \right]
\end{align*}
\]

(13)

We have after manipulation

\[
K_{03} = -\frac{2}{m_{q}^2} C_{44} \varepsilon_{12},
\]

(14)

\[
L_{05} - L_{06} = \frac{1}{m_{q}^2} \left[ 4 C_{44} \varepsilon_{12} + K_{02} (2m_{0}^2 - m_{q}^2) \right].
\]

(15)

Equations (9)–(15) provide the relations between the thermodynamic parameters and the measured magnetostriction (in equation (11), \( L_{01} - L_{02} \) is treated as a single parameter because when suffering homogeneous elastic fields, the terms related to \( L_{01} \) and \( -L_{02} \) can be switched to each other through integration by part; equation (15) is understood in the same way). Further study shows that the term with coefficient \( L_{03} \) in equation (6) is not affecting the magnetostriction measurement. It only has an effect on the inhomogeneous distribution of periodic strains in space, for which the value of parameter \( L_{03} \) cannot be examined through ordinary magnetostriction measurement. For materials in points groups with lower symmetry, we need to perform magnetostriction measurements in more directions to get a full set of parameters and the solution of the parameters is generally more complicated.
3. Elastic Gibbs energy density with magnetoelastic interactions for chiral magnets

In the Helmholtz free energy density given in equation (1), the elastic strains and the magnetization are chosen as the independent variables of the system, which is applicable to materials with a fixed displacement, or approximately, with displacement boundary conditions. When the stress boundary conditions are given instead, the elastic Gibbs free energy density \[33\] is the appropriate thermodynamic potential to be used, which can be derived from the Helmholtz free energy density through the Legendre transformation. We derive it as follow for chiral magnets suffering a coupled magnetoelastic field. From equation (4), all strain-related terms in \( w_{\text{me}} \) are linear to the strain components. Therefore equation (4) can be reformulated as

\[
\begin{align*}
\dot{w}_{\text{me}} &= \varepsilon \cdot \vec{g}(\mathbf{m}, \nabla \mathbf{m}), \\
\end{align*}
\]

where

\[
\vec{g}(\mathbf{m}, \nabla \mathbf{m}) = \left[ \delta_{11}(\mathbf{m}, \nabla \mathbf{m})\delta_{22}(\mathbf{m}, \nabla \mathbf{m})\delta_{33}(\mathbf{m}, \nabla \mathbf{m})\delta_{23}(\mathbf{m}, \nabla \mathbf{m})\delta_{13}(\mathbf{m}, \nabla \mathbf{m})\delta_{12}(\mathbf{m}, \nabla \mathbf{m}) \right]^T, \\
\vec{g}_m(\mathbf{m}, \nabla \mathbf{m}) &= \frac{\partial w_{\text{me}}}{\partial \varepsilon_i} \text{ if } i = j, \\
\vec{g}_m(\mathbf{m}, \nabla \mathbf{m}) &= \frac{1}{2} \frac{\partial w_{\text{me}}}{\partial \varepsilon_{ij}} \text{ if } i \neq j, \\
\varepsilon &= \left[ \varepsilon_{11} \varepsilon_{22} \varepsilon_{33} 2\varepsilon_{23} 2\varepsilon_{13} 2\varepsilon_{12} \right]^T.
\]

The elastic Gibbs energy density of the system can be derived through the following Legendre transformation

\[
g(\mathbf{\sigma}, \mathbf{m}, \nabla \mathbf{m}) = w - \varepsilon \cdot \mathbf{\sigma}, \\
\]

where \( \mathbf{\sigma} = [\sigma_{11} \sigma_{22} \sigma_{33} \sigma_{23} \sigma_{13} \sigma_{12}]^T \). After manipulation, we have from equation (19)

\[
g(\mathbf{\sigma}, \mathbf{m}, \nabla \mathbf{m}) = w_{\text{mag}} - w_{\text{el}}(\mathbf{\sigma}) + \mathbf{\sigma}^T \mathbf{S} \mathbf{\dot{g}} - \frac{1}{2} \mathbf{\dot{g}}^T \mathbf{S} \mathbf{\dot{g}}, \\
\]

where \( w_{\text{el}}(\mathbf{\sigma}) = \frac{1}{2} \mathbf{\sigma}^T \mathbf{S} \mathbf{\sigma} \), and \( \mathbf{S} = \mathbf{C}^{-1} \) is the flexibility matrix.

Equation (20) is a general formula of the elastic Gibbs energy density. To use it, one has to first consider the specific symmetry requirement of the material studied, and derive the particular form of \( \vec{g} \) from equation (5), and then substitute it into equation (20). Notice that the last term on the right-hand-side of equation (20) is generally very complicated, while its effect is to induce a modification of the magneto-crystalline anisotropy and other higher order magnetic anisotropy terms. Yet according to previous analysis [30], for materials with a magnetostriction smaller than \( 10^{-4} \) (which is generally true), the effect of this term is negligible. For different point groups, the detailed expressions of \( \vec{g}_m(\mathbf{m}, \nabla \mathbf{m}) \) are given in supplementary material part C.

4. Thermodynamic potentials for epitaxial thin films of chiral magnets

Sometimes the material studied possess a mixed boundary condition. The most frequently encountered case of this type is an epitaxial thin film, which is mechanically clamped in-plane, and subjected to forces on the out-of-plane surfaces. In this case, the appropriate thermodynamic potential is:

\[
g_{\text{TF}} = w - \varepsilon_{33} \sigma_{33} - 2\varepsilon_{23} \sigma_{23} - 2\varepsilon_{13} \sigma_{13}, \\
\]

where the independent variable for the elastic fields are \( \varepsilon_{11}, \varepsilon_{22}, \varepsilon_{33}, \sigma_{23}, \sigma_{13} \) and \( \sigma_{12} \). The expression of \( g_{\text{TF}} \) depends on the symmetry of the material studied. For orthorhombic materials (group D₂ or C₂ᵥ), we have

\[
g_{\text{TF}} = w_{\text{mag}} + g_{\dot{d}} + \varepsilon_{11} \dot{g}_{11} + \varepsilon_{22} \dot{g}_{22} + 2\varepsilon_{12} \dot{g}_{23} + \frac{1}{C_{33}}(\sigma_{33} - C_{13} \varepsilon_{11} - C_{23} \varepsilon_{22}) \dot{g}_{33} \\
+ \frac{\sigma_{23}}{C_{44}} \dot{g}_{23} + \frac{\sigma_{13}}{C_{55}} \dot{g}_{13} - \frac{\dot{g}_{11}^2}{2C_{33}} - \frac{\dot{g}_{22}^2}{2C_{44}} - \frac{\dot{g}_{33}^2}{2C_{55}}, \\
\]

where \( g_{\dot{d}} \) denotes the part of free energy density that depends merely on the elastic strains, and in the case of an epitaxial strain is equal to a constant, for which its detailed expression is not expanded. The expressions of \( \dot{g}_i \) differ for different groups and can be found in supplementary material part C.
For trigonal materials (group $D_3$, $C_3$ or $C_{3v}$), we have
\[
g_{TF} = w_{\text{mag}} + g_\ell + \varepsilon_{11}\bar{\gamma}_{11} + \varepsilon_{22}\bar{\gamma}_{22} + 2\varepsilon_{12}\bar{\gamma}_{12} + \frac{1}{C_{33}}(\sigma_{33} - C_{13}\varepsilon_{11} - C_{13}\varepsilon_{22})\bar{\gamma}_{33} \\
+ \frac{1}{C_{44}}(\sigma_{23} - C_{14}\varepsilon_{11} + C_{14}\varepsilon_{22})\bar{\gamma}_{23} + \frac{1}{C_{44}}(\sigma_{13} - 2C_{14}\varepsilon_{12})\bar{\gamma}_{13} = \frac{\bar{\gamma}_{33}^2}{2C_{33}} - \frac{\bar{\gamma}_{23}^2}{2C_{44}} - \frac{\bar{\gamma}_{13}^2}{2C_{44}}.
\]
(23)

For hexagonal materials (group $D_6$, $C_6$ or $C_{6v}$), we have
\[
g_{TF} = w_{\text{mag}} + g_\ell + \varepsilon_{11}\bar{\gamma}_{11} + \varepsilon_{22}\bar{\gamma}_{22} + 2\varepsilon_{12}\bar{\gamma}_{12} + \frac{1}{C_{33}}(\sigma_{33} - C_{13}\varepsilon_{11} - C_{13}\varepsilon_{22})\bar{\gamma}_{33} \\
+ \frac{\sigma_{23}}{C_{44}}\bar{\gamma}_{23} + \frac{\sigma_{13}}{C_{44}}\bar{\gamma}_{13} = \frac{\bar{\gamma}_{33}^2}{2C_{33}} - \frac{\bar{\gamma}_{23}^2}{2C_{44}} - \frac{\bar{\gamma}_{13}^2}{2C_{44}}.
\]
(24)

For cubic materials (group $O$ or $T$), we have
\[
g_{TF} = w_{\text{mag}} + g_\ell + \varepsilon_{11}\bar{\gamma}_{11} + \varepsilon_{22}\bar{\gamma}_{22} + 2\varepsilon_{12}\bar{\gamma}_{12} + \frac{1}{C_{11}}(\sigma_{11} - C_{13}\varepsilon_{11} - C_{13}\varepsilon_{22})\bar{\gamma}_{11} \\
+ \frac{\sigma_{23}}{C_{44}}\bar{\gamma}_{23} + \frac{\sigma_{13}}{C_{44}}\bar{\gamma}_{13} = \frac{\bar{\gamma}_{33}^2}{2C_{33}} - \frac{\bar{\gamma}_{23}^2}{2C_{44}} - \frac{\bar{\gamma}_{13}^2}{2C_{44}}.
\]
(25)

5. Epitaxial thin films of chiral magnets in group $T$, $C_{3v}$, and $D_{2d}$ under equiaxed strain and pure shear

Now we provide some concrete applications of the theory constructed above. We consider two most commonly encountered mechanical boundary conditions for epitaxial thin films: (a) equiaxed in-plane misfit strain $\varepsilon_{11} = \varepsilon_{22} = \varepsilon_\ell$, $\varepsilon_{12} = \varepsilon_{21} = 0$, and (b) pure shear $\varepsilon_{12} = \varepsilon_{21} = 0$. Notice that $\varepsilon$ and $\gamma$ are assumed to be constants in this work. We derive the concrete form of thermodynamic potentials to be used for materials in three different types of point groups (group $T$, $C_{3v}$ and $D_{2d}$) subjected to the two conditions of misfit strains. These three point groups are chosen since they provide hosts for three types of MECs respectively: Bloch SkX [1–4, 22], Néel SkX [5, 35–38], and Anti-SkX [8], which have already been observed in experiments. Helimagnets in group $T$ includes MnSi [1, 39], Fe0.5Co0.5Si [2], and FeGe [3, 22, 40], etc; helimagnets in group $C_{3v}$ includes GaV$_4$S$_8$ [5]; helimagnets in group $D_{2d}$ includes Mn$_{1.4}$Pt$_{0.6}$Pd$_{0.3}$Sn [8].

For materials in group $T$ subjected to condition (a), the thermodynamic potential to be used is reduced to
\[
g_{TF} = w_{\text{mag}} + g_\ell + K_{T1}^\ell\varepsilon m^2 + K_{T1}^m m^2 + L_{T1}^\ell\varepsilon m_1 m_2 + L_{T2}^\ell\varepsilon (m_3 m_{12} + m_2 m_{31}) + L_{T3}^\ell\varepsilon m_3 m_{12},
\]
(26)

where $L_{T1}^\ell = L_{T1} - L_{T3} - L_{T2} + L_{T5} - \frac{2\varepsilon_{11}}{\varepsilon_{11}}(L_{T4} - L_{T6})$, $L_{T2}^\ell = L_{T1} - L_{T3} - L_{T2} + L_{T5} + L_{T4} - L_{T6}$, $L_{T3}^\ell = -(1 + \frac{\varepsilon_{11}}{\varepsilon_{11}})(L_{T1} - L_{T3} + L_{T2} - L_{T5})$, and $K_{T1}^\ell$ and $K_{T1}^m$ are the magnetoelastic thermodynamic parameters for materials in group $T$, which are defined in supplementary material part B. When $K_{T1}^\ell = 0$ and $L_{T1}^\ell = -L_{T1}^\ell$, equation (26) reduces to the thermodynamic potential for materials in group $O$.

Equation (26) shows that for epitaxial helimagnets in group $T$ subjected to equiaxed in-plane misfit strain, the emergent deformation of the MECs are completely determined by six thermodynamic parameters: $K_{T1}^\ell$, $K_{T1}^m$, $K_{T2}^\ell$, $L_{T1}^\ell$, $L_{T2}^\ell$, and $L_{T3}^\ell$. Here we investigate the effect of each individual magnetoelastic terms in equation (26). $K_{T1}^\ell\varepsilon m^2$ reduces the Curie temperature of the material by $K_{T1}^\ell\varepsilon$ [here and in the discussion below we have used equation (2) instead of equation (3)]. $K_{T1}^\ell m_1 m_2$ and $K_{T1}^\ell m_2 m_1$ induce an uniaxial anisotropy, which is studied in previous works [41, 42]. The term with a coefficient $L_{T1}^\ell$ is ineffective when studying 2D MECs in the $r_1-r_2$ plane. The term with a coefficient $L_{T2}^\ell$ shares the form of the original DMI of the material, for which its effect is to change the lattice constant of the MEC studied without causing a pattern deformation. The term with a coefficient $L_{T3}^\ell$ induces an anisotropy of DMI, which causes deformation and even phase transition of MECs (figure 1). To be more specific, a negative (positive) $L_{T3}^\ell\varepsilon$ stretches the Bloch SkX in direction $r_1$ ($r_2$), and as the value of $L_{T3}^\ell\varepsilon$ decreases (increases), the Bloch SkX finally evolves to the In-plane single Q (IPSQ) phase.

One should notice that in a certain range of magnetic field, as the value of positive $L_{T3}^\ell\varepsilon$ increases, a ‘cell division’ phenomena occurs: the skyrmions in the SkX is suddenly stretched into a pair of ‘linked’ skyrmions, which form a novel magnetic state called pSKX. The ‘particle’ of pSKX, a paired-skyrmion, is different from a biskyrmion [43] or a dipole skyrmion [44]. To be more specific, a paired-skyrmion is
composed of two identical skyrmions; a biskyrmion is composed of two skyrmions with the opposite in-plane magnetization distribution and the same out-of-plane magnetization distribution; a dipole composed of two identical skyrmions; a biskyrmion is composed of two skyrmions with the opposite phase diagrams and magnetization distributions in figure 1 and other figures are introduced in the methods section. As a result, the topological density of the system undergoes a sudden change during a SkX-pSkX phase transition, which is realized by smoothly changing the applied misfit strains. The details for calculating the state. As a result, the topological density of magnetization field with

\[ \lambda = T - 4 \]  

Figure 1. (a, c) phase diagrams and (\( A_i, c_i \)), for \( i = 1-6 \) and \( j = 1, 2 \), magnetization field configurations of the magnetic phases appearing in epitaxial thin films in Group T subjected to (a) equi-axed in-plane misfit strain \( \varepsilon_{11} = \varepsilon_{22} = \varepsilon \), and (c) pure shear \( \varepsilon_{44} = \varepsilon \). The x-axis of (a) is defined by \( \lambda_{12} = L_T^i, c_i \), and the y-axis of (c) is defined by \( \lambda_{12} = L_T^j, c_j \). (b) plots the variation of the topological density of magnetization field with \( b \) corresponding to the loading condition of (a), and the result is calculated at \( \lambda_{12} = 0.2 \). In (a, c), the vectors illustrate the distribution of the in-plane magnetization components with length proportional to their magnitude, while the colored density plot illustrates the distribution of the out-of-plane magnetization component. The black (white) solid line plots the deformed (undeformed) position of the Wigner–Seitz cell of SkX due to presence of misfit strains.

where

\[
T^* = 4 (\text{if we assume that } T^{*} = 4), \quad \gamma_0 = 2
\]

For materials in group \( C_{2h} \), subjected to condition (b), the thermodynamic potential to be used is reduced to

\[
\mathcal{G}_{TF} = \mathcal{G}_{mag} + \mathcal{G}_{el} + 2K_T \gamma m_1 m_2 + L_{T1} \gamma m_1 m_1 + L_{T2} \gamma m_2 m_2 + L_{T3} \gamma m_3 m_3 \\
+ L_{T4} \gamma m_2 m_2 + L_{T5} \gamma m_3 m_3
\]

For materials in group \( C_{3v} \), subjected to condition (a), the thermodynamic potential to be used is reduced to

\[
\mathcal{G}_{TF} = \mathcal{G}_{mag} + \mathcal{G}_{el} + 2K_T \gamma m_1 m_2 + L_{T1} \gamma m_1 m_1 + L_{T2} \gamma m_2 m_2 + L_{T3} \gamma m_3 m_3 \\
+ L_{T4} \gamma m_2 m_2 + L_{T5} \gamma m_3 m_3
\]

where \( L_{T4} = L_{T12} - L_{T10}, L_{T5} = L_{T11} - L_{T8} \). When \( L_{T9} = -L_{T7}, L_{T13} = 0, \) and \( L_{T11} - L_{T8} = L_{T10} - L_{T12} \), equation (27) reduces to the thermodynamic potential for materials in group \( O \). Here we investigate the effect of each individual terms in equation (27). The term with a coefficient \( K_{T1} \) can be transformed to uniaxial anisotropy in a particular direction in the \( r_1-\tau_2 \) plane (i.e. after a rotation of coordinates in the \( r_1-\tau_2 \) plane, the term with a coefficient \( K_{T4} \) can take a similar form to \( K_{T1} \) in equation (26), for which they possess similar effects). Generally speaking, for all the point groups studied, all terms with a coefficient \( K_{Ti} \) can be transformed to uniaxial anisotropy in a specific direction, for which we will not analyze the effect of terms with a coefficient \( K_{Gi} \) repeatedly in the discussion for materials in other point groups. Terms with coefficients \( L_{T7}, L_{T9} \), and \( L_{T13} \) are ineffective when studying 2D MECs in the \( r_1-\tau_2 \) plane. The two terms with coefficients \( L_{T4} \) and \( L_{T5} \) induce anisotropy of DMI, which cause deformation and even phase transition of MECs (figure 1). To be more specific, a negative (positive) \( L_{T4} \) stretches the Bloch SkX in direction \([110]\) \([110]\), and as the value of \( L_{T4} \) decreases (increases), the Bloch SkX finally evolves to the IPSQ phase. The term with a coefficient \( L_{T5} \) has an exactly opposite effect to that of the term with a coefficient \( L_{T4} \) (if we assume that \( L_{T5} = -L_{T4} \), the \( L_{T5} \) term has exactly the same effect as the \( L_{T4} \) term).

For materials in group \( C_{3v} \), subjected to condition (a), the thermodynamic potential to be used is reduced to

\[
\mathcal{G}_{TF} = \mathcal{G}_{mag} + \mathcal{G}_{el} + 2K_T \gamma m_1 m_2 + L_{T1} \gamma m_1 m_1 + L_{T2} \gamma m_2 m_2 + L_{T3} \gamma m_3 m_3 \\
+ L_{T4} \gamma m_2 m_2 + L_{T5} \gamma m_3 m_3
\]
\[
g_{\text{TF}} = u_{\text{mag}} + g_\ell + K_{C_{3v}}^* \varepsilon \mathbf{m}^2 + K_{C_{3v}}^* \varepsilon \mathbf{m}_1^2 + L_{C_{3v}}^* \varepsilon (m_1 m_{1,1} - m_2 m_{1,2}) + L_{C_{3v}}^* \varepsilon (m_1 m_{1,3} + m_2 m_{2,3}) + L_{C_{3v}}^* \varepsilon (m_3 m_{3,3} + m_3 m_{3,1}),
\]

where \( K_{C_{3v}}^* = K_{C_{3v},1} + K_{C_{3v},2} - \frac{2 \gamma_1}{C_4} K_{C_{3v},7}, K_{C_{3v}}^* = 2 K_{C_{3v},4} - K_{C_{3v},1} - K_{C_{3v},3} + \frac{4 \gamma_2}{C_3} (K_{C_{3v},7} - K_{C_{3v},8}), L_{C_{3v}}^* = \frac{1}{2} (L_{C_{3v}} - L_{C_{3v},6} - L_{C_{3v},7} - \frac{2 \gamma_3}{C_3} L_{C_{3v},8}) L_{C_{3v}}^* = L_{C_{3v},2} + L_{C_{3v},8} - \frac{4 \gamma_2}{C_3} L_{C_{3v},25}, L_{C_{3v}}^* = 2(L_{C_{3v},14} - \frac{\gamma_1}{C_4} L_{C_{3v},28}), L_{C_{3v}}^* = L_{C_{3v},10} + L_{C_{3v},17} - L_{C_{3v},4} - L_{C_{3v},9} + \frac{2 \gamma_2}{C_3} L_{C_{3v},27} - \frac{4 \gamma_2}{C_3} L_{C_{3v},26}, \) and \( K_{C_{3v}}, L_{C_{3v}}^* \) are the magnetoelastic thermodynamic parameters for materials in group \( C_{3v} \), which are defined in supplementary material part B. If \( L_{C_{3v}}^* = 0 \), equation (28) reduces to the thermodynamic potential for materials in group \( C_{3v} \). Here we investigate the effect of each individual terms in equation (28). Terms with coefficients \( L_{C_{3v},1}, L_{C_{3v},3}, \) and \( L_{C_{3v},8} \) are ineffective when studying 2D MECs in the \( r_1 - r_2 \) plane. The term with a coefficient \( L_{C_{3v},4}^* \) shares the form of the original DMI of the material, for which its effect is to change the lattice constant of the MEC studied without causing a pattern deformation.

For materials in group \( C_{3v} \) subjected to condition (b), the thermodynamic potential to be used is reduced to

\[
g_{\text{TF}} = u_{\text{mag}} + g_\ell + (K_{C_{3v},1} - K_{C_{3v},3}) \gamma_1 m_1 m_2 + 2K_{C_{3v},2} \gamma_2 m_1 m_3 - \frac{C_4}{C_{44}} K_{C_{3v},5} \gamma (m_1^2 + m_2^2) - 2 \frac{C_4}{C_{44}} K_{C_{3v},6} \gamma m_1 m_3 + L_{C_{3v}}^* \gamma m_1 m_3 + L_{C_{3v}}^* \gamma (m_1 m_{2,1} - m_2 m_{1,2}) + L_{C_{3v}}^* \gamma (m_1 m_{1,1} - m_1 m_{1,2}) + g_\ell,
\]

where

\[
g_\ell = L_{C_{3v}}^* \gamma (m_1 m_{1,1} + m_2 m_{2,2}) + \frac{C_4}{C_{44}} (K_{C_{3v},15} \gamma (m_1 m_{1,3} + m_2 m_{2,3}) - \frac{C_4}{C_{44}} (K_{C_{3v},16} \gamma (m_1 m_{1,3} - m_2 m_{2,3}) + \frac{C_4}{C_{44}} (K_{C_{3v},19} - L_{C_{3v},22} \gamma m_1 m_{1,3},
\]

and \( L_{C_{3v}}^* = (L_{C_{3v},6} - L_{C_{3v},20}), L_{C_{3v}}^* = \frac{\gamma_6}{C_4} L_{C_{3v},17} - L_{C_{3v},20}), L_{C_{3v}}^* = \frac{1}{L_{C_{3v},10} - L_{C_{3v},12} + L_{C_{3v},9}), L_{C_{3v}}^* = \frac{2 \gamma_6}{C_4} (L_{C_{3v},18} - L_{C_{3v},21}), L_{C_{3v}}^* = \frac{1}{L_{C_{3v},10} - L_{C_{3v},12} + L_{C_{3v},9}), L_{C_{3v}}^* = \frac{4 \gamma_6}{C_4} L_{C_{3v},17} - L_{C_{3v},20}), L_{C_{3v}}^* = \frac{1}{L_{C_{3v},10} - L_{C_{3v},12} + L_{C_{3v},9}), \)

\( + L_{C_{3v}}^* = \frac{1}{L_{C_{3v},10} - L_{C_{3v},12} + L_{C_{3v},9}), \) when \( K_{C_{3v}} = K_{C_{3v}} = L_{C_{3v}} = L_{C_{3v}}^* = L_{C_{3v}} = L_{C_{3v}}^* = L_{C_{3v}}^* = 0 \) and \( g_\ell = 0, \) equation (29) reduces to the thermodynamic potential for materials in group \( C_{3v} \). Terms in equation (30) are ineffective when studying 2D MECs in the \( r_1 - r_2 \) plane. The four terms with coefficients \( L_{C_{3v}}^* \), \( L_{C_{3v}}^* \), \( L_{C_{3v}}^* \), and \( L_{C_{3v}}^* \) induce anisotropy of DMI, which cause deformation and even phase transition of MECs (Figure 2). To be more specific, as the modulus of \( L_{C_{3v}}^* \) increases, the Néel skyrmions in SkX are stretched in axis \( r_1 \), while the lattice constant of the Néel SkX is kept unchanged. The term with a coefficient \( L_{C_{3v}}^* \) causes pure shearing of the Néel SkX: a positive (negative) \( L_{C_{3v}}^* \) rotates and stretches the SkX in direction \( \{110\} \) \((\{110\})\). The term with a coefficient \( L_{C_{3v}}^* \) causing uniaxial elongation of the SkX: a positive (negative) \( L_{C_{3v}}^* \) stretches the SkX in axis \( r_1 (r_2) \). One should notice that in a certain range of magnetic field, as the value of negative \( L_{C_{3v}}^* \) decreases, the SkX-pSkX phase transition with is observed in Bloch SkX for materials in group \( T \) occurs again. Similarly, the topological density of the system undergoes a sudden change during a SkX-pSkX phase transition of materials in group \( C_{3v} \).

For materials in group \( D_{2d} \) subjected to condition (a), the thermodynamic potential to be used is reduced to

\[
g_{\text{TF}} = u_{\text{mag}} + g_\ell + K_{D_{2d}}^* \varepsilon \mathbf{m}^2 + K_{D_{2d}}^* \varepsilon \mathbf{m}_1^2 + L_{D_{2d}}^* \varepsilon (m_1 m_{1,1} + m_1 m_{1,2}) + L_{D_{2d}}^* \varepsilon (m_1 m_{1,3} + m_2 m_{2,3}) + L_{D_{2d}}^* \varepsilon (m_3 m_{3,3} + m_3 m_{3,1}),
\]

where \( K_{D_{2d}} = K_{D_{2d},1} + K_{D_{2d},2} - \frac{2 \gamma_1}{C_4} K_{D_{2d},6}, K_{D_{2d}}^* = 2(K_{D_{2d},3} + \frac{\gamma_1}{C_4} K_{D_{2d},8} - \frac{\gamma_1}{C_4} K_{D_{2d},7}) - K_{D_{2d},2}, \)

\( L_{D_{2d}} = L_{D_{2d},1} + L_{D_{2d},2} - \frac{2 \gamma_1}{C_4} L_{D_{2d},18}, L_{D_{2d}}^* = L_{D_{2d},16} + L_{D_{2d},26} - L_{D_{2d},2} - L_{D_{2d}}^* + \frac{2 \gamma_1}{C_4} L_{D_{2d},19} - \frac{2 \gamma_1}{C_4} L_{D_{2d},20}, \) and \( K_{D_{2d}}, L_{D_{2d}} \) are the magnetoelastic thermodynamic parameters for materials in group \( D_{2d} \). In equation (31), the term with a coefficient \( L_{D_{2d}} \) is ineffective when studying 2D MECs in the \( r_1 - r_2 \) plane. The term with a coefficient \( L_{D_{2d}}^* \) shares the form of the original DMI of the material, for which its effect is to change the lattice constant of the MEC studied without causing a pattern deformation.

For materials in group \( D_{2d} \) subjected to condition (b), the thermodynamic potential to be used is reduced to
Figure 2. (a, b, c, d) phase diagrams and \((a_i, b_i, c_i, d_j)\), for \(i = 1, 2\) and \(j = 1–4\), magnetization field configurations of the MECs appearing in epitaxial thin films in Group \(C_3v\) subjected to pure shearing misfit strain \(\varepsilon_{12}=\frac{\gamma}{2}\). The \(x\)-axis of (a, b, c, d) is defined respectively by \(\lambda_{C_3v1} = L_{C_3v5} \gamma\), \(\lambda_{C_3v2} = L_{C_3v6} \gamma\), \(\lambda_{C_3v3} = L_{C_3v7} \gamma\), \(\lambda_{C_3v4} = L_{C_3v8} \gamma\). (e) plots the variation of the topological density of magnetization field with \(b\) corresponding to the loading condition of (d), and the result is calculated at \(\lambda_{C_3v4} = -0.2\).

\[ g_{TF} = w_{mag} + g_d + 2K_{D_2d} \gamma m_1 m_2 + L_{D_2d} \gamma (m_1 m_{1,3} + m_2 m_{2,3}) + L_{D_2d} \gamma (m_3 m_2,2 + m_3 m_{1,1}), \tag{32} \]

where \(L_{D_2d} = (L_{D_2d,9} - L_{D_2d,8})\). In equation (32), terms with coefficients \(L_{D_2d,9}\) and \(L_{D_2d,9}\) are ineffective when studying 2D MECs in the \(r_1–r_2\) plane. The term with a coefficient \(L_{D_2d,8}\) causes pure shearing of the Anti-SkX (figure 3); a positive (negative) \(L_{D_2d,8}^*\) rotates and stretches the SkX in direction [110] ([110]).

deforation and phase transition of MECs in group

materials, the condition of misfit strains is usually more complicated, and all the strain-induced DMI terms

coexist with different strength depending on the material studied. The analysis performed in this work can

be regarded as basic case studies of the large variety of possible deformation pattern and novel MECs that
can appear due to presence of coupled magnetoelastic fields.

6. Methods

In this section, we introduce how to use the free energy density derived in the above section to perform free
energy minimization for different MECs. In particular, we discuss the terms in the magnetoelastic free
energy density which may lead to anisotropic deformation or phase transition of the MECs. For epitaxial
thin films in group

subjected to condition (a), we should discuss the equilibrium state of the material by

Using equation (33), we assume that

in equation (33), for different values of

the parameter

we truncate the expansion given in equation (33) at

and substitute it into equation (26) (one should

the deformed (undeformed) position of the Wigner–Seitz cell of SkX due to presence of misfit strains. [45, 46]:

where

denotes the reciprocal vectors of the undeformed EC, which is ordered in such a way that

and

In equation (33),

is a constant vector, and

with

being the emergent elastic strains of the EC, and

being the emergent rotational angle. In practice,

we truncate the expansion given in equation (33) at

and substitute it into equation (26) (one should

m = m₀ + \sum_{i=1}^{n} \sum_{j=1}^{n_i} m_{q_{ij}} e^{i \mathbf{q}_{ij} \cdot (\mathbf{l} - \mathbf{p}) r} \tag{33} \]

\[
\mathbf{F}^e = \begin{bmatrix} e_{ii}^e & e_{ij}^e + \omega^e \\ e_{ji}^e & e_{jj}^e \end{bmatrix} \tag{34} \]

with \( e_{ij}^e \) being the emergent elastic strains of the EC, and \( \omega^e \) being the emergent rotational angle. In practice,
notice that when \( n = 3 \), we have considered 18 Fourier terms in equation (33) while the well-known triple-Q approximation considers only 6 terms). At given values of \( \lambda_T \) and \( b \), we minimize the free energy with respect to \( m_0, m_3, c_{ij}, \) and \( \omega \), which determines the equilibrium magnetization. Repeating this free energy minimization process for different values of \( \lambda_T \) and \( b \), one obtains the variation of magnetization with them, as well as the corresponding phase diagrams.

The calculation process introduced above is generally useful. For epitaxial thin film of materials in group \( T \) subjected to condition (b), we consider the following thermodynamic parameters: \( \lambda_T = L_{T_4} \gamma \), \( \lambda_T = L_{T_5} \gamma \), and \( b \), and minimize the free energy given in equation (27). For epitaxial thin film of materials in group \( C_{3v} \), subjected to condition (b), we consider the following thermodynamic parameters: \( \lambda_{C_{3v}} = L_{C_{3v}} \gamma \), \( \lambda_{C_{3v}} = L_{C_{3v}} \gamma \), \( \lambda_{C_{3v}} = L_{C_{3v}} \gamma \), \( \lambda_{C_{3v}} = L_{C_{3v}} \gamma \), and \( b \), and minimize the free energy given in equation (29). For epitaxial thin film of materials in group \( D_{2d} \) subjected to condition (b), we consider the following thermodynamic parameters: \( \lambda_{D_{2d}} = L_{D_{2d}} \gamma \) and \( b \), and minimize the free energy given in equation (31). Softwares that permit symbolic calculations are helpful when doing the derivation, and we have used mathematica in this work.
