**Background:** The venoms of some scorpions are rich in bioactive components that may be used in the development and discovery of new antibacterial drugs. The venoms have many components, such as neurotoxins, salts, proteins and peptides with therapeutic properties, and can rapidly eliminate a broad range of bacteria. This study evaluated the anti-bacterial activity of *Odontobuthus bidentatus*’ crude venom against typical Gram-positive and negative bacteria, such as *Staphylococcus aureus*, *Bacillus subtilis*, and *Escherichia coli*.

**Methods:** The antibacterial effects of the crude venom were evaluated using Minimal Inhibitory Concentration (MIC) and MTT assays and its IC_{50} value was determined, using GraphPad software.

**Results:** The crude venom significantly inhibited the growth of both Gram-positive and negative bacteria. Also the MTT results showed that the crude venom significantly reduced the viability of *E. coli*, *S. aureus*, and *B. subtilis* bacteria compared with that for the controls. The IC_{50} values of the venom for *E. coli*, *S. aureus*, and *B. subtilis* were 30.19, 17.64, and 24.13 µM, respectively.

**Conclusion:** The findings suggest that the venom of *O. bidentatus* scorpion has antibacterial properties. Also, our results offer preliminary clues toward the development of new antibacterial agents and new drugs with high therapeutic potentials for use in animals and humans.

**Keywords:** Antimicrobial activity; *Odontobuthus bidentatus*; Scorpion venom; *E. coli*, *S. aureus* and *B. subtilis*; Gram-positive and Gram-negative bacteria
Odontobuthus bidentatus (O. bidentatus) is a member of the Botheida family and the Odontobuthus genus can be found in six Iranian provinces (Khuzestan, Kerman, Bushehr, Fars, Ilam and Hormozgan) and in the Iraqi province of Baghdad [15]. The anti-cancerous activity of the venom of this scorpion in currently under investigation [16, under review]. However, no investigation is available on the antibacterial activity of this venom. We extracted and investigated the antibacterial property of the venom from the Iranian scorpion O. bidentatus on three bacterial strains. They consisted of one Gram negative, i.e., E. coli, and two Gram positive bacteria, Staphylococcus aureus and Bacillus subtilis.

Materials and Methods

Preparation of scorpion venom: The scorpions O. bidentatus were collected from Khuzestan and Hormozgan provinces in Iran, and the venom was extracted by electrical stimulation from the telson. This structure is situated at the end of the scorpion’s tail and contains the venom glands and a sharp, curved stinger. The venomous mixture was centrifuged at 8000 g for 15 min at 4° C, and the supernatant was lyophilized and stored at -20° C for further experiments. In order to prepare the venom solution, the lyophilized powder was dissolved in a medium, and the protein concentration was determined by the Bradford method [17]. The scorpions were kept individually in glass containers under recommended laboratory conditions, fed live house flies and flour beetle larvae based on a standard protocol.

Gram-positive and Gram-negative bacterial strains: Reference bacterial strains, Staphylococcus aureus (ATCC 6538), Escherichia coli (ATCC 25922), and Bacillus subtilis (ATCC 19659) were obtained from Iranian Biological Resource Center (Tehran, Iran) and were maintained on nutrient agar slants (Oxoid, Hampshire, UK) at 4° C.

Determination of minimal inhibitory concentration: The bacteria were cultured in Muller Hinton broth (Sigma Aldrich; St. Louis, MO, USA) at 37° C. The bacteria (5×10^5 CFU/mL) were incubated in 96-well microplate at varying concentrations of O. bidentatus crude venom (serial dilutions of 100 µg/ml of crude venom) in a final volume of 100 µL/well. Tetracycline antibiotic (50 µg/mL) and bacterial suspension were used as positive and negative controls, respectively. The microplates were incubated at 37° C and after 16 h, the Optic Density (OD) was measured at 620 nm, using a BioRad microplate reader (Philadelphia, PA, USA). The minimal inhibitory concentration (MIC) is the lowest concentration of antimicrobial agents that causes 100% inhibition of the growth of the bacteria. The results were reported as means of three independent experiments. MIC was calculated using formula 1:

\[ \text{MIC} = (1 - \frac{\text{OD sample} - \text{OD blank}}{\text{OD negative control} - \text{OD blank}}) \times 100 \]

Determination of cellular viability: The colorimetric assay of 3-(4,5-Dimethyl thiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT) was used to assess the cellular viability. Similarly to the MIC assay, 5 µL of MTT dye (5 mg/mL) was added to each well after 16 h and the plate was incubated in dark at 37° C for 1 h. Then, 100 µL DMSO was added to each well and incubated in dark for another 2 h, and the absorbance was read at 595 nm. Also, the IC_{50} of the venom was determined using the Graphpad Prism software, v. 8. The assay was repeated in triplicate for each concentration and the cell viability was determined, using formula 2:

\[ \text{Viability} = \frac{\text{OD sample} - \text{OD blank}}{\text{OD negative control} - \text{OD blank}} \times 100 \]

Statistical analysis: The MTT and MIC assays were performed in triplicate and the results reported as Mean±SD. The data were analyzed using Graphpad Prism 8 Software (La Jolla, CA, USA). The venom’s activity at various concentrations was compared to that of the control group, using one-way ANOVA and Tukey’s tests.

Results

MIC assay: The O. bidentatus crude venom significantly inhibited the growth of both Gram-positive (S. aureus & B. subtilis) and Gram-negative (E. coli) bacteria. As seen in Figure 1, the MIC results indicated that the growth rates of the three bacteria were inhibited dose-dependently when treated with the venom at a range of concentrations from 6.25 µg/mL to 100 µg/mL (P<0.0001).

MTT assay: As seen in Figure 2, the crude venom significantly reduced the viability rates of E. coli, S. aureus, and B. subtilis bacteria in a dose dependent manner compared to that noted for the negative controls. The results also demonstrated that the venom significantly decreased the viability rates of both E. coli and S. aureus.
bacteria, respectively, at the concentrations of 6.25 µg/mL to 100 µg/mL and 3.125 µg/mL to 100 µg/mL (Figures 2A & 2B). A comparable inhibition of the viability of *B. subtilis* required 12.5 µg/mL to 100 µg/mL of the venom (Figure 2C). The results indicated that the IC$_{50}$ values for *E. coli*, *S. aureus*, and *B. subtilis* were 30.19, 17.64, and 24.13 µM, respectively (Figures 2D, 2E & 2F).

**Discussion**

Scorpions are known to use their venom to disinfect themselves from bacteria and fungi [9]. Various studies have shown that scorpion venom contains active components with antimicrobial activity [18, 19]. The present study provides evidence that the crude venom extracted from *O. bidentatus* has antibacterial effects on all the three Gram-positive and Gram-negative bacteria tested. The data from the MIC analysis showed that the crude venom has a significant inhibitory effect on the three bacterial at almost all concentrations used. The results
of MTT assay also confirmed the MIC results. According to the MTT results, the lowest IC50 of the venom was observed for S.aureus at 17.64 µM concentration.

As suggested by structure–function experiments, cationic peptides are active mostly against Gram-negative bacteria while hydrophobic peptides significantly inhibit Gram-positive bacteria [20, 21]. Interestingly, it appears that the venom of O. bidentatus contains both cationic and hydrophobic peptides, inhibiting both Gram-negative and Gram-positive strains. The antibacterial activity of some scorpions’ venoms has been investigated previously [22]. Ahmed et al. investigated the antibacterial activity of the crude venom of H. xanthopus scorpion on B. subtilis, S. typhimurium, E. faecalis and P. aeruginosa. They found that the venom inhibited the growth of all bacteria strains efficiently [22].

Ermes et al. studied the antimicrobial activity of the crude venom from Leirus abdullahbayrami scorpion (Buthidae family) on Gram-negative (E. coli, E. aerogenes and P. aeruginosa) and Gram-positive (L. monocytogenes) bacteria. They also investigated the effects of the venom against two fungal species (C. krusei and C. albicans). The results showed that the antimicrobial effect was stronger against Gram-negative than Gram-positive bacteria [23].

Samy et al. investigated the antibacterial activity of venoms from snake, scorpions (Buthus hottenota and Buthus martensii Karsch) and bees [6]. They showed that the scorpion venoms significantly inhibited the growth of S. Aureus, Proteus mirabilis, Proteus vulgaris, Enterobacter aerogenes, Pseudomonas aeruginosa and E. Coli bacteria [6]. Salama and Geasa studied the antimicrobial activity of venoms from three Egyptian scorpions (Leirus quinquestriatus, Androctonus amoreuxi and Androctonus australis) [24]. In their study, the antimicrobial activities of these venoms against four Gram-positive and Gram-negative bacteria (Bacillus cereus, Bacillus subtilis, Citrobacter freundii and Klebsiella pneumoniai) were evaluated. They showed that L. quinquestriatus venom had a significant antibacterial effect against B. subtilis and C. freundii. In contrast, A. amoreuxi and A. australis venoms did not have a noticeable effect on the tested bacteria [24].

Our study demonstrated for the first time the potential activity of the venom from O. bidentatus scorpion against the three bacterial strains. To this date, no other study has been conducted on the antibacterial activity of this venom. The findings of this study may be useful in future investigations to uncover the antibacterial mechanisms of O. bidentatus venom.

Limitations

This study focused on the antibacterial effects of the whole venom of O. bidentatus scorpion. In future studies, we recommend that the venom’s fractions be investigated to explore the most effective antibacterial component(s).

Conclusions

The findings suggest that the venom of O. bidentatus scorpion has antibacterial properties against S. Aureus, B. subtilis and E. Coli. Also, our results offer preliminary clues toward the development of new antibacterial drugs and agents with high therapeutic potentials for use in animals and humans. The findings may provide a foundation for future investigations on the putative antimicrobial properties of similar toxins and will expand our toxicology knowledge applicable to the design and development of new agents generated from them.

Ethical Considerations

Compliance with ethical guidelines

Scorpions (Odontobuthus bidentatus) were collected with permission of the Ministry of Health, Govt. of Iran and their venom were extracted in the Razi Institute with required permission.

Funding

The present paper was extracted from the PhD. dissertation of the first author, Department of Biology, Faculty of Basic Sciences, Razi University, Kermanshah.
