Abstract In this article we introduce the local versions of the Voevodsky category of motives with $\mathbb{F}_p$-coefficients over a field $k$, parametrized by finitely generated extensions of $k$. We introduce the so-called flexible fields, passage to which is conservative on motives. We demonstrate that, over flexible fields, the constructed local motivic categories are much simpler than the global one and more reminiscent of a topological counterpart. This provides handy ‘local’ invariants from which one can read motivic information. We compute the local motivic cohomology of a point for $p = 2$ and study the local Chow motivic category. We introduce local Chow groups and conjecture that over flexible fields these should coincide with Chow groups modulo numerical equivalence with $\mathbb{F}_p$-coefficients, which implies that local Chow motives coincide with numerical Chow motives. We prove this conjecture in various cases.

Keywords: motive, motivic cohomology, Chow groups, numerical equivalence of cycles, Milnor’s operations.

1. Introduction

The category of algebraic varieties is rich and marvelous but not additive, in the sense that one cannot add morphisms between varieties. The program to ‘linearize’ the algebro-geometric world was first introduced in the 1960s by A. Grothendieck, who proposed the category of Chow motives. It is a close relative of the category of correspondences, where objects are smooth projective varieties and morphisms are algebraic cycles on the product modulo rational equivalence. The result is a tensor additive category, because we can add (and subtract) algebraic cycles and multiply them externally. Moreover, one does not have to limit oneself to only rational equivalence of cycles. Instead, it is possible to consider algebraic, numerical or homological equivalence and, actually, the theory of Chow groups here can be substituted by any oriented cohomology theory (in the sense of [11, Definition 3.1.1] or [9, Definition 1.1.2]). Chow motives of varieties split into smaller pieces, which permits expressing in a precise form some of the similarities observed in the behaviour of different varieties. In particular, the Tate motives appear responsible for the cellular structure. The above Grothendieck category has innumerate remarkable applications, but it deals with smooth projective varieties only. At the same time, in
topology, motives were known for a long time in full generality in the form of singular complexes of topological spaces. This problem was solved by V. Voevodsky in [20], who constructed the triangulated category of motives $DM(k)$ over a field $k$ (around the same time, alternative constructions were proposed by M. Hanamura and M. Levine). This category of Voevodsky contains the Grothendieck category of Chow motives as a full additive subcategory closed under direct summands and, in particular, permits studying these ‘pure’ objects by triangulated methods. Voevodsky supplied his category with many flexible tools and his motives found numerous bright applications, most notable of which is to the proof of Milnor’s and Bloch-Kato’s conjectures.

In this article, we study Voevodsky category $DM(k; \mathbb{F}_p)$ with finite coefficients over a field of characteristic zero. We introduce the local versions $DM(E/k; \mathbb{F}_p)$ of this category, corresponding to all finitely generated field extensions $E/k$ together with the natural localisation functors $\varphi_E : DM(k; \mathbb{F}_p) \to DM(E/k; \mathbb{F}_p)$. In the case of a trivial extension we get the isotropic motivic categories $DM(E/E; \mathbb{F}_p)$ and localisation functors can be specialised further to isotropic functors $\psi_E : DM(k; \mathbb{F}_p) \to DM(E/E; \mathbb{F}_p)$. Such isotropic versions (in the appropriate situation) appear to be much simpler than the original global category and allow one to obtain ‘local’ invariants of motives, residing in a rather simple world.

The construction of isotropic motivic category is based on the notion of an anisotropic variety, that is, a variety that does not have closed point of degree prime to a given prime $p$ (thus the fact that coefficients are finite is really essential). The rough idea is to ‘kill’ the motives of all anisotropic varieties over $k$. This idea belongs to T. Bachmann, who in [1] considered the full tensor triangulated subcategory $DQM^{gm}$ of $DM(k; \mathbb{F}_2)$ generated by motives of smooth projective quadrics and studied it with the help of functors $\Phi^E : DQM^{gm} \to K^b(Tate(\mathbb{F}_2))$ to the category of bigraded $\mathbb{F}_2$-vector spaces. These functors were defined by the property that they ‘kill’ the motives of $k$-quadrics, which stay anisotropic over $E$ (and act ‘identically’ on Tate motives). In our approach, the same idea comes naturally from the development of some ideas of Voevodsky and that of [14]. Namely, we consider the natural $\otimes$-idempotents in the Voevodsky category, given by motives $X_Q$ of Čech simplicial schemes corresponding to smooth varieties $Q$ over $k$. The respective projectors naturally commute with each other and form a partially ordered set $\mathcal{P}$, where $X_Q \geq X_P$ if there exists a correspondence of degree 1 (modulo $p$) $Q \sim P$ (Definition 2.1). This condition is equivalent to the fact that $X_Q \otimes X_P = X_Q$. That is, a stronger projector ‘consumes’ a weaker one. Moreover, there is a natural map $X_Q \to X_P$ (the unique lifting of the projection $X_Q \to T$). For connected varieties, this is actually a condition on their generic points. The ‘smallest’ idempotent is the unit object of the tensor structure, given by the trivial Tate motive $T$ (which corresponds to $P = \text{Spec}(k)$). Thus, we get a $\mathcal{P}$-parametrized filtration by idempotents on the unit object. We may consider the upper graded components of this filtration. In other words, we take a particular idempotent $X_P$ and mod-out all strictly large ones; that is, we consider the colimit of idempotents $X_P \otimes \widetilde{X}_Q$, for all $X_Q \geq X_P$, where $\widetilde{X}_Q$ is an idempotent complementary to $X_Q$. The result is a certain idempotent in $DM(k; \mathbb{F}_p)$, which actually can be described in terms of the Čech simplicial scheme of a variety with infinitely many connected components. This idempotent will be zero unless $P$ is connected up to equivalence (i.e., can be replaced by a connected variety with the same $X$) and, in the latter case, it depends
Isotropic motives

only on \( E = k(P) \), and even only on the equivalence class of such finitely generated field extension \( E/k \). Applying the respective projector to \( \text{DM}(k; \mathbb{F}_p) \) we obtain the motivic category \( \text{DM}(E/k; \mathbb{F}_p) \) of the extension \( E/k \) (Definition 2.3). It is naturally a full tensor localising subcategory of the Voevodsky category \( \text{DM}(k; \mathbb{F}_p) \) supplied with the localisation functor \( \varphi : \text{DM}(k; \mathbb{F}_p) \to \text{DM}(E/k; \mathbb{F}_p) \). In the case of a trivial extension \( k/k \), we get the isotropic motivic category \( \text{DM}(k/k; \mathbb{F}_p) \), where the respective projector is the colimit of projectors \( \tilde{X}_Q \otimes \), where \( Q \) runs over all varieties with \( \tilde{X}_Q \neq T \) or, in other words, over all anisotropic varieties. Because \( \tilde{X}_Q \otimes M(Q) = 0 \), such a projector ‘kills’ the motives of all anisotropic varieties. These local motivic categories were discovered in an attempt to find an alternative approach to the functors of Bachmann (mentioned above) and were briefly introduced in [17, Section 4].

Our next point is that to extract the local information in a meaningful form one should first pass to an appropriate field extension of a ground field. This is illustrated by the example of an algebraically closed ground field \( k \), where, up to equivalence, there is only one (trivial) class of field extensions, represented by the extension \( k/k \), and the respective localisation functor \( \varphi : \text{DM}(k; \mathbb{F}_p) \to \text{DM}(k/k; \mathbb{F}_p) \) is an equivalence of categories (see Remark 2.12). Thus, it is conservative but not very interesting. At the same time, there is a large class of fields for which the localisation really simplifies things. These are the so-called flexible fields introduced in Subsection 1.2; that is, fields that are purely transcendental extensions of infinite (transcendence) degree of some other fields. Note that one can always pass from an arbitrary field \( k_0 \) to a flexible one \( k_0(t_1, t_2, \ldots) \) without losing any motivic information. The class of flexible fields is closed under finitely generated extensions. Thus, if the ground field \( k \) is flexible, then all of the functors \( \psi_E : \text{DM}(k; \mathbb{F}_p) \to \text{DM}(E/E; \mathbb{F}_p) \) take values in ‘flexible’ isotropic categories. And such categories are really simple. We examine them from two points of view: We look at the isotropic motivic cohomology of a point \( H^{*,*'}_{M}(k/k; \mathbb{F}_p) \) and at the isotropic Chow motivic category \( \text{Chow}(k/k; \mathbb{F}_p) \).

We show in Theorem 3.7 that, in the case of a flexible field, \( H^{*,*'}_{M}(k/k; \mathbb{F}_2) \) is the external algebra \( \Lambda_{\mathbb{F}_2}(r_{ij}|i \geq 0) \) with the generators in one-to-one correspondence with Milnor’s operations and the action of the latter given by \( Q_i(r_{ij}) = 1 \) and \( Q_j(r_{ij}) = 0 \), for \( i \neq j \). Thus, the answer is the same for all flexible fields, and all of these cohomology elements are ‘rigid’, because we can get 1 from any such nonzero element by applying an appropriate combination of Milnor’s operations. The answer is also remarkable in the sense that Milnor’s operations are encoded into the structure of isotropic motivic category (in the form of their ‘inverses’ \( r_{ij} \)). The computation is done with the help of the Voevodsky technique used in the proof of Milnor’s conjecture, and our answer explains to some extent why Milnor’s operations played such an important role in Voevodsky’s proof (see Theorem 3.5). Finally, the answer is drastically different from the ‘global’ one and the localisation functor \( H^{*,*'}_{M}(k, \mathbb{F}_2) \to H^{*,*'}_{M}(k/k; \mathbb{F}_2) \) is zero outside the bidegree \((0,0)\). We are restricted to the prime \( p = 2 \), because in our calculations the crucial role is played by [15, Corollary 3], and there is no analogue of this statement for \( p > 2 \).

It appears that isotropic Chow motives are closely related to the numerical equivalence of cycles with \( \mathbb{F}_p \)-coefficients. We conjecture that, in the case of a flexible field, isotropic Chow groups \( \text{Ch}^{*,*}_{k/k} \) (describing \( \text{Homs} \) between such motives) coincide with the Chow
groups (with $\mathbb{F}_p$-coefficients) modulo numerical equivalence $Ch^*_{\text{Num}}$ (see Conjecture 4.7). This would imply that the category of isotropic Chow motives is equivalent to the category of Chow motives modulo numerical equivalence (with finite coefficients). We prove this conjecture for divisors, for varieties of dimension $\leq 5$, and for cycles of dimension $\leq 2$ (Theorem 4.11). In particular, this implies that isotropic Chow groups are finite-dimensional in these situations. This also shows that the projection $Ch^* \to Ch^*_k/k$ factors through the third theory of higher type $Ch^{(3)}$ (where $Ch^{(0)} = Ch^*$ is the original theory of rational type and $Ch^{(1)} = Ch^*_{\text{alg}}$ is the algebraic version; see Definition 4.3 and Proposition 4.25). The proof of Theorem 4.11 constitutes the bulk of this article. It is by induction on the dimension of a variety $X$. Using the moving technique introduced in Section 6, we show that after an appropriate blow-up, any class $u$ numerically equivalent to zero may be represented by a cycle supported on a smooth connected divisor $Z$ and numerically trivial already on $Z$. An important step here is to represent $u$ by the class of a smooth connected subvariety and numerically annihilate certain characteristic classes of it (cf. Corollaries 6.11, 6.12). Interestingly, the latter is achieved by a combination of appropriate blow-ups and Steenrod operations, depending on a prime involved.

This article is organized as follows. After briefly discussing flexible fields in Subsection 1.2, in Section 2 we introduce the local motivic category with $\mathbb{F}_p$-coefficients as well as its Chow-motivic version. In Section 3 we study the isotropic motivic cohomology of a point, and Section 4 is devoted to the study of isotropic Chow groups and the respective Chow-motivic category. In Section 5 we expand the definition of local motivic category beyond prime coefficients. Finally, in Section 6 we prove various geometric results used in Section 4.

1.1. Notations and conventions

 Everywhere below $k$ will denote a field of characteristic zero. $	ext{Sm}_k$ is the category of smooth quasi-projective varieties over $k$. $Ch^*$ is the Chow groups $CH^*/\mathbb{F}_p$ with finite coefficients, where $p$ is some prime (in Section 6, $p$ will be replaced by an arbitrary natural number $n$). DM$(k; F_p)$ will denote the triangulated category of Voevodsky motives over a field [20], [3] and DM$_{gm}(k; F_p)$ will denote the full triangulated subcategory of geometric motives in it. $L$ is the Lazard ring; that is, the coefficient ring of the universal formal group law.

1.2. Flexible fields

Traditionally, algebraic geometry was considered over algebraically closed fields. Over such fields, every algebraic variety (of finite type) has a rational point, which simplifies many things. In the case of a general field the standard approach is to consider the passage to its algebraic closure. Note, however, that (torsion) information is lost under such a passage. One of the aims of the current article is to convince the reader that there are other directions one can pursue. Namely, I propose to move instead in the direction of the so-called flexible fields. Such fields have the advantage that one does not
have to distinguish between the ground field and finitely generated purely transcendental extensions of it. This helps with many algebro-geometric constructions.

**Definition 1.1.** Let us call a field \( k \) flexible if it is a purely transcendental extension of countable infinite degree of some other field: \( k = k_0(t_1, t_2, \ldots) = k_0(\mathbb{F}^\infty) \).

Note that any finitely generated extension of a flexible field \( k \) is itself flexible. Indeed, such an extension is defined by finitely many generators and relations, which can ‘spoil’ only finitely many of the original transcendental generators. Thus, all of the points of the large Nisnevich site of \( \text{Spec}(k) \) are flexible. On the other hand, we have the following.

**Remark 1.2.** The natural restriction functor \( \text{DM}(k_0; \mathbb{F}_p) \to \text{DM}(k; \mathbb{F}_p) \) is conservative. Therefore, we can substitute a field by a flexible one without losing any motivic information. \( \Box \)

The main property of flexible fields we will need is the following obvious observation.

**Proposition 1.3.** Let \( k \) be a flexible field, \( X \), variety of finite type over \( k \), and \( E/k \) be a finitely generated purely transcendental field extension. Then there exists a commutative diagram

\[
\begin{array}{ccc}
X & \xrightarrow{\cong} & X_E \\
\downarrow & & \downarrow \\
\text{Spec}(k) & \xrightarrow{\cong} & \text{Spec}(E)
\end{array}
\]

with horizontal maps isomorphisms (over some subfield \( k_0 \)).

**Proof.** Let \( k = k_0(t_1, t_2, \ldots) \). Then \( X \) is defined over some finitely generated purely transcendental extension \( F \) of \( k_0 \) such that \( k/F \) is purely transcendental. That is, there is a variety \( \overline{X} \) of finite type over \( F \), such that \( \overline{X}_k = X \). Because extensions \( k/F \) and \( E/F \) are isomorphic, we get what we need. \( \Box \)

**2. Motivic category of a field extension**

Everywhere below \( \text{DM}(k; \mathbb{F}_p) \) will denote the triangulated motivic category of Voevodsky over \( \text{Spec}(k) \) with \( \mathbb{F}_p \)-coefficients (see [20], [3]). We will construct the local versions of this category, corresponding to all finitely generated field extensions \( E/k \), or in other words, to all points of the big Nisnevich site over \( \text{Spec}(k) \). The local motivic categories will be obtained as full localising subcategories of a global one by application of certain projectors. These projectors will be produced using Čech simplicial schemes.

Let \( P \) be a smooth variety over \( k \). The Čech simplicial scheme \( \check{\text{C}}ech(P) \) has graded components \( (\check{\text{C}}ech(P))_n = P^{\times (n+1)} \) with faces and degeneracy maps given by partial projections and partial diagonals. This object is an analogue of the contractible space \( EG \) in topology, and it will be contractible in the Morel-Voevodsky homotopic motivic category as long as \( P \) has a rational point, though in general it ‘measures’ how far we are from acquiring such a point. In particular, it is a form of a point, because it certainly contracts over algebraic closure. Let us denote the motive of \( \check{\text{C}}ech(P) \) as \( X_P \). The natural
projection \( \check{C}ech(P) \to \text{Spec}(k) \) provides the morphism \( X_P \to T \) to a trivial Tate motive, which is an isomorphism if and only if \( P \) has a zero cycle of degree 1 (modulo \( p \), in our case) (a ‘weak form’ of a rational point) - [14, Theorem 2.3.4]. This gives an exact triangle

\[
X_P \longrightarrow T \longrightarrow \tilde{X}_P \longrightarrow X_P[1],
\]

where \( X_P \) and \( \tilde{X}_P \) are mutually orthogonal idempotents

\[
X_P \otimes X_P \cong X_P; \quad \tilde{X}_P \otimes \tilde{X}_P \cong \tilde{X}_P; \quad X_P \otimes \tilde{X}_P \cong 0.
\]

Thus, the functors of a tensor product with these objects:

\[
X_P \otimes: \text{DM}(k; \mathbb{F}_p) \to \text{DM}(k; \mathbb{F}_p); \quad \tilde{X}_P \otimes: \text{DM}(k; \mathbb{F}_p) \to \text{DM}(k; \mathbb{F}_p)
\]

are projectors. This defines the semi-orthogonal decomposition of the category \( \text{DM}(k; \mathbb{F}_p) \) as an extension of \( \tilde{X}_P \otimes \text{DM}(k; \mathbb{F}_p) \) by \( X_P \otimes \text{DM}(k; \mathbb{F}_p) \), because there are no Homs from the latter subcategory to the former one (by [14, Theorem 2.3.2], which is basically [19, Lemma 4.9]).

For different varieties, these projectors naturally commute and we have canonical (co-associative, respectively associative) identifications

\[
X_P \otimes X_Q \cong X_{P \times Q} \quad \text{and} \quad \tilde{X}_P \otimes \tilde{X}_Q \cong \tilde{X}_{P \boxtimes Q}
\]

(note that endomorphism rings of \( X_X \) and \( \tilde{X}_V \) are either \( \mathbb{F}_p \), or zero; [14, Theorems 2.3.2, 2.3.3], and such an endomorphism is fixed by the map \( X_X \to T \), respectively \( T \to \tilde{X}_V \)). Thus, the tensor product of any (finite) number of such objects can be always expressed as \( X_R \otimes \tilde{X}_S \), for some \( R \) and \( S \).

Each \( X_P \) corresponds to a subsheaf \( \chi_P \) of the constant sheaf \( T = \mathbb{F}_p \) on the big Nisnevich site over \( \text{Spec}(k) \) defined as follows. For a smooth connected quasi-projective variety \( X \), \( \chi_P(X) = \mathbb{F}_p \), if \( P \) has a zero-cycle of degree 1 over \( k(X) \), and it is zero otherwise. Equivalently, \( \chi_P(X) = \mathbb{F}_p \) exactly when \( \tilde{X}_P \otimes M(X) = 0 \) [14, Theorems 2.3.6, 2.3.3]. Respectively, \( \tilde{X}_P \) corresponds to the quotient sheaf \( \tilde{X}_P = T/\chi_P \). We can introduce an order on the set of \( X_Q S \) as follows.

**Definition 2.1.** We say that \( X_Q \geq X_P \) if any of the following equivalent conditions is satisfied:

1. The natural map \( X_Q \otimes X_P \cong X_Q \otimes X_P \) is an isomorphism.
2. The natural map \( \tilde{X}_Q \otimes \tilde{X}_P \cong \tilde{X}_P \) is an isomorphism.
3. The map \( X_Q \to T \) factors through \( X_P \to T \).
4. \( P \) has a zero-cycle of degree 1 modulo \( p \) over the generic point of every component of \( Q \).
5. \( \chi_Q \) is a subsheaf of \( \chi_P \).

Here (1) \( \Leftrightarrow \) (2) is automatic from the definition; (2) \( \Rightarrow \) (5) follows from the description of \( \chi_P \) above; (5) \( \Rightarrow \) (4) follows from the fact that \( \chi_P(Q_i) = \mathbb{F}_p \), for any connected component \( Q_i \) of \( Q \); (4) \( \Rightarrow \) (1) is [14, Theorem 2.3.6]; (1) \( \Rightarrow \) (3) is straightforward; and, finally, (3) \( \Rightarrow \) (1) is clear, because \( X_Q \otimes \tilde{X}_P \otimes (X_Q \to T) \) is the identity map of \( X_Q \otimes \tilde{X}_P \).
Note that the relation $\mathcal{X}_Q \supseteq \mathcal{X}_P$ is obviously transitive. In the case of connected varieties, this relation may be formulated in terms of the respective field extensions (generic points). Let $E/k$ and $F/k$ be two finitely generated extensions of a field of characteristic zero. Let $P/k$ and $Q/k$ be smooth projective varieties whose function fields are identified with $E$ and $F$.

**Definition 2.2.** We say that $F/k \supseteq E/k$ if there exists a correspondence of degree 1 (with $\mathbb{F}_p$-coefficients) $Q \leadsto P$. We call extensions ‘equivalent’ $F/k \sim E/k$ if $F/k \supseteq E/k$ and $E/k \supseteq F/k$.

By the composition of correspondences, the property $F/k \supseteq E/k$ is transitive. It is also equivalent to the condition $\mathcal{X}_Q \supseteq \mathcal{X}_P$ above. If $k/l$ is a field extension, then $F/k \supseteq E/k$ implies that $F/l \supseteq E/l$.

Let $P$ be some smooth variety (of finite type) over $k$. Let $Q$ be the disjoint union of all connected varieties $Q/k$, such that $\mathcal{X}_Q \supseteq \mathcal{X}_P$ (thus it is a smooth variety but with infinitely many components), and let $\mathcal{X}_Q$ be the motive of the respective Čech simplicial scheme, which is still an idempotent in $\text{DM}(k; \mathbb{F}_p)$, and $\tilde{\mathcal{X}}_Q$ be the complementary idempotent. Define

$$\Upsilon_P := \tilde{\mathcal{X}}_Q \otimes \mathcal{X}_P.$$  

We can view $\Upsilon_P$ as a colimit of projectors $\tilde{\mathcal{X}}_Q \otimes \mathcal{X}_P$, where $Q$ runs over all smooth projective varieties of finite type with $\mathcal{X}_Q \supseteq \mathcal{X}_P$.

Note that if $P$ is not connected up to equivalence – that is, if $P$ cannot be substituted by a connected variety with the same $\mathcal{X}$ – then $\Upsilon_P = 0$. Indeed, let $P_1$ be a ‘minimal’ component; that is, $\mathcal{X}_{P_1} \supseteq \mathcal{X}_P$ implies that $\mathcal{X}_{P_1} = \mathcal{X}_P$. Suppose that there exists another component $P_2$ with $\mathcal{X}_{P_2} \not\supseteq \mathcal{X}_{P_1}$. Let $\hat{P}_1$ be the union of all of the components equivalent to $P_1$. Then for $Q_1 = P \setminus \hat{P}_1$ and $Q_2 = \hat{P}_1$ we have $\mathcal{X}_{Q_1} \supseteq \mathcal{X}_P$, $\mathcal{X}_{Q_2} \supseteq \mathcal{X}_P$, but $\mathcal{X}_{Q_1 \cup Q_2} \neq \mathcal{X}_P$.

Now we can define the local motivic category corresponding to a finitely generated extension $E/k$ (cf. [17, Section 4]).

**Definition 2.3.** Let $E/k$ be a finitely generated extension and $P/k$ be a smooth connected variety with $k(P) = E$. Define the ‘motivic category of the extension $E/k$’ as the full localising subcategory

$$\text{DM}(E/k; \mathbb{F}_p) = \Upsilon_P \otimes \text{DM}(k; \mathbb{F}_p)$$

of $\text{DM}(k; \mathbb{F}_p)$ and the ‘local geometric category’ $\text{DM}_{gm}(E/k; \mathbb{F}_p)$ as the full thick triangulated subcategory of $\text{DM}(E/k; \mathbb{F}_p)$ generated by (local) motives of smooth projective varieties.

This definition does not depend on the choice of a smooth model $P$, because $\mathcal{X}_P$ depends on $k(P)$ only. Moreover, it depends only on the $\sim$-equivalence class of an extension $E/k$.

In the case of a trivial extension, we obtain (cf. [17, Section 4]) the following.

**Definition 2.4.** The ‘isotropic motivic category’ is the full localising subcategory $\text{DM}(k/k; \mathbb{F}_p)$ of $\text{DM}(k; \mathbb{F}_p)$ given by $\Upsilon_{\text{spec}(k)} \otimes \text{DM}(k; \mathbb{F}_p)$, and the geometric version $\text{DM}_{gm}(k/k; \mathbb{F}_p)$ is the full thick triangulated subcategory of it generated by (isotropic) motives of smooth projective varieties.
Proof. We need to prove that \( \tilde{\psi}_E : \text{DM}(k; \mathbb{F}_p) \to \text{DM}(E/k; \mathbb{F}_p) \) parametrized by all points of the big Nisnevich site over \( \text{Spec}(k) \). These can be further specialised to isotropic realisations

\[
\tilde{\psi}_E : \text{DM}(k; \mathbb{F}_p) \to \text{DM}(E/E; \mathbb{F}_p).
\]

The following result shows that there are no unexpected objects in the isotropic geometric category.

**Proposition 2.5.** The category \( \text{DM}_{gm}(k/k; \mathbb{F}_p) \) is the idempotent completion of the full subcategory \( \Upsilon_{\text{Spec}(k)} \otimes \text{DM}_{gm}(k; \mathbb{F}_p) \) of \( \text{DM}(k; \mathbb{F}_p) \).

**Proof.** We need to prove that \( \Upsilon_{\text{Spec}(k)} \otimes \text{DM}_{gm}(k; \mathbb{F}_p) \) is closed under cones. For this, it is sufficient to show that, for any objects \( U, V \) of \( \text{DM}_{gm}(k; \mathbb{F}_p) \) and a map \( \tilde{f} : \tilde{X}_Q \otimes U \to \tilde{X}_Q \otimes V \) (where \( Q \) is the disjoint union of all anisotropic varieties over \( k \)), there is a map \( f : U' \to V' \) in \( \text{DM}_{gm}(k; \mathbb{F}_p) \), such that \( f \otimes id_{\tilde{X}_Q} \cong \tilde{f} \). Composing the map \( \tilde{f} \) with \( U \to \tilde{X}_Q \otimes U \) we obtain a map \( g : U \to \tilde{X}_Q \otimes V \) with the property that \( g \otimes id_{\tilde{X}_Q} \cong \tilde{f} \). Define \( (\tilde{X}_Q)_{<n} \) as \( \text{Cone}(\tilde{X}_Q)_{<n-1} \to T \) and \( (\tilde{X}_Q)_{>n} \) as \( \text{Cone}(\tilde{X}_Q)_{<n} \to \tilde{X}_Q \). Then \( (\tilde{X}_Q)_{>n} \) is an extension of \( \mathcal{M}(Y)[r] \), for some smooth varieties \( Y \) and \( r \). Because \( U \) and \( V \) are geometric, for sufficiently large \( n \), there are no \( \text{Hom} \)s from \( U \) to \( (\tilde{X}_Q)_{>n} \otimes V \). Hence, the map \( g \) can be lifted to a map \( f' : U \to (\tilde{X}_Q)_{<n} \otimes V \), which, in turn, can be lifted to a geometric map \( f : U \to (\tilde{X}_Q)_{<n} \otimes V \), for some anisotropic variety \( Q \) of finite type over \( k \). Because \( \tilde{X}_Q \otimes (\tilde{X}_Q)_{<n} = \tilde{X}_Q \), for any \( n \geq 0 \), we obtain that \( f \otimes id_{\tilde{X}_Q} \cong \tilde{f} \).

We can describe \( \text{Hom} \)'s from geometric isotropic motives as follows. For an object \( X \) of \( \text{DM}(k; \mathbb{F}_p) \) and some idempotent \( \xi \), we will denote by the same letter the image of \( X \) in \( \xi \otimes \text{DM}(k; \mathbb{F}_p) \).

**Proposition 2.6.** Let \( U \in \text{Ob}(\text{DM}_{gm}(k; \mathbb{F}_p)) \) and \( V \in \text{Ob}(\text{DM}(k; \mathbb{F}_p)) \). Then

\[
\text{Hom}_{\text{DM}(k; \mathbb{F}_p)}(U, V) = \text{colim}_{\mathcal{X}_Q \neq T} \text{Hom}_{\tilde{X}_Q \otimes \text{DM}(k; \mathbb{F}_p)}(U, V),
\]

where the colimit is taken over all of the functors \( \tilde{X}_S \otimes : \tilde{X}_R \otimes \text{DM}(k; \mathbb{F}_p) \to \tilde{X}_S \otimes \text{DM}(k; \mathbb{F}_p) \), for \( \mathcal{X}_R \geq \mathcal{X}_S \neq T \). In other words, \( Q \) runs over all anisotropic varieties over \( k \).

**Proof.** We have \( \text{Hom}_{\text{DM}(k; \mathbb{F}_p)}(U, V) = \text{Hom}_{\text{DM}(k; \mathbb{F}_p)}(\Upsilon_{\text{Spec}(k)} \otimes U, \Upsilon_{\text{Spec}(k)} \otimes V) \), and the latter can be identified with \( \text{Hom}_{\text{DM}(k; \mathbb{F}_p)}(U, \tilde{X}_Q \otimes V) \), where \( Q \) is the disjoint union of all anisotropic varieties over \( k \). But because \( U \) is geometric, any map \( U \to \tilde{X}_Q \otimes V \) factors through \( U \to \tilde{X}_Q \otimes V \), for some anisotropic \( Q \) of finite type, and the map \( U \to \tilde{X}_Q \otimes V \) vanishes when extended to a map to \( \tilde{X}_Q \otimes V \) if and only if there exists an anisotropic \( Q' \).
with $\mathcal{X}_Q \supseteq \mathcal{X}_{Q'}$, such that the composition $U \to \tilde{\mathcal{X}}_Q \otimes V \to \tilde{\mathcal{X}}_{Q'} \otimes V$ is zero. Thus, our Hom-group can be identified with the

$$\colim_{\mathcal{X}_Q \not\supseteq T} \text{Hom}_{\text{DM}(k; \mathbb{F}_p)}(U, V),$$

where the colimit is taken over a directed system (as $\mathcal{X}_{Q_i} \supseteq \mathcal{X}_{\underline{i}_i}, q_i$ and if $\mathcal{X}_{Q_i} \not\supseteq T$, for each $i$), then $\mathcal{X}_{\underline{i}_i}, q_i \not\supseteq T$, because the coefficients are $\mathbb{F}_p$).

Geometric motives vanishing in the local category can also be detected by projectors corresponding to varieties of finite type. Let $P$ be a smooth connected variety with $E = k(P)$.

**Proposition 2.7.** An object $U$ of $\text{DM}_{gm}(k; \mathbb{F}_p)$ vanishes in $\text{DM}(E/k; \mathbb{F}_p)$ if and only if there is a variety $Q$ of finite type over $k$, with $\mathcal{X}_Q \supseteq \mathcal{X}_P$ and $\tilde{\mathcal{X}}_Q \otimes \mathcal{X}_P \otimes U = 0$.

**Proof.** If $\mathcal{Y}_P \otimes U = 0$, then $(\tilde{\mathcal{X}}_Q \otimes U)_E = 0$, where, as above, $Q$ is the disjoint union of all smooth connected varieties $Q$ over $k$, with $\mathcal{X}_Q \supseteq \mathcal{X}_P$. That means that the projection $(\mathcal{X}_Q \otimes U \to U)_E$ has a section (from the right). But because $U$ is geometric, such a section will factor through some section of $(\mathcal{X}_Q \otimes U \to U)_E$ for some variety $Q$ of finite type over $k$ with $\mathcal{X}_Q \supseteq \mathcal{X}_P$. Hence, $(\tilde{\mathcal{X}}_Q \otimes U)_E = 0$ (as $U_E$ is a direct summand of $\mathcal{X}_Q \otimes U_E$, so $\tilde{\mathcal{X}}_Q \otimes U_E$ is a direct summand of it as well, but the latter object is stable under $\tilde{\mathcal{X}}_Q \otimes$, whereas the former one is killed by it). But, according to [14, Theorem 2.3.5], the functor $\mathcal{X}_P \otimes \text{DM}(k; \mathbb{F}_p) \to \text{DM}(E; \mathbb{F}_p)$ is conservative. Hence, $\tilde{\mathcal{X}}_Q \otimes \mathcal{X}_P \otimes U = 0$ in $\text{DM}(k; \mathbb{F}_p)$.

Because $\tilde{\mathcal{X}}_Q \otimes M(Q) = 0$, the projection to the isotropic motivic category $\text{DM}(k/k; \mathbb{F}_p)$ kills the motives of all anisotropic varieties over $k$. Hence the name of this category.

**Remark 2.8.** The isotropic motivic category $\text{DM}(k/k; \mathbb{F}_p)$ is the Verdier localisation of $\text{DM}(k/k; \mathbb{F}_p)$ modulo the localising subcategory $\mathcal{A}$ generated by motives of anisotropic varieties. Indeed, an object $U$ of $\text{DM}(k/k; \mathbb{F}_p)$ vanishes in $\text{DM}(k/k; \mathbb{F}_p)$ if and only if $U = U \otimes \mathcal{X}_Q$, where $Q$ is the disjoint union of all connected anisotropic varieties $Q/k$. Hence, $U$ belongs to $\mathcal{A}$, because this subcategory is a tensor ideal. By the universal property of the Verdier localisation, $\psi_E : \text{DM}(k/k; \mathbb{F}_p) \to \text{DM}(k/k; \mathbb{F}_p)$ is equivalent to $\text{DM}(k/k; \mathbb{F}_p) \to \text{DM}(k/k; \mathbb{F}_p)/\mathcal{A}$.

We have functoriality for the ‘denominator’ of the extension $E/k$. Suppose that we have a tower of fields $L \subset F \subset E$, and $P/L, Q/L$ are smooth projective varieties with $L(P) = E$ and $\mathcal{X}_Q \supseteq \mathcal{X}_P$. Then $Q$ remains anisotropic over $L(P)$, and thus over $F(P)$ (because $F \subset L(P)$). Hence, $\mathcal{X}_Q|_F \supseteq \mathcal{X}_P|_F$. Thus, we get a natural functor

$$\text{DM}(E/L; \mathbb{F}_p) \longrightarrow \text{DM}(E/F; \mathbb{F}_p).$$

\[1\] I am grateful to T. Bachmann for pointing this out.
The following result shows that, in the case of a flexible ground field, we can pass from (geometric) local realisations \{ϕ_E|E/k—f.g. extension\} to isotropic realisations \{ψ_E|E/k—f.g. extension\} without losing any information.

**Proposition 2.9.** Let \(E/k\) be a finitely generated extension of a flexible field. Then the functor

\[
\text{DM}_{\text{gm}}(E/k; \mathbb{F}_p) \rightarrow \text{DM}_{\text{gm}}(E/E; \mathbb{F}_p)
\]

is conservative on the image of \(φ_E\).

**Proof.** Let us start with purely transcendental extensions.

**Lemma 2.9.1.** Let \(E/L/k\) be a tower of finitely generated extensions where \(L/k\) is a purely transcendental extension of a flexible field. Then the functor

\[
\text{DM}_{\text{gm}}(E/k; \mathbb{F}_p) \rightarrow \text{DM}_{\text{gm}}(E/L; \mathbb{F}_p)
\]

is conservative on the image of \(φ_E\).

**Proof.** Let \(L = k(\mathbb{A}^n)\) and \(E = k(\overline{R})\) for some smooth variety \(\overline{R}/k\). Let \(\overline{U} \in \text{Ob}(\mathcal{X}_R \otimes \text{DM}_{\text{gm}}(k; \mathbb{F}_p))\) be an object vanishing in \(\text{DM}_{\text{gm}}(E/L; \mathbb{F}_p)\). Then, according to Proposition 2.7, there exists a variety \(\overline{Q}/L\) of finite type such that \(\mathcal{X}_{\overline{Q}} \geq \mathcal{X}_{\overline{R}_L}\) and \(\overline{U} \otimes \tilde{\mathcal{X}}_{\overline{Q}} = 0\) in \(\text{DM}(L; \mathbb{F}_p)\). The condition \(\mathcal{X}_{\overline{Q}} \geq \mathcal{X}_{\overline{R}_L}\) means that we have an \(L\)-correspondence \(\overline{α}: \overline{Q} \sim \overline{R}_L\) of degree one, and there is no such correspondence in the opposite direction. Because \(k = k_0(\mathbb{P}^\infty)\) is flexible, varieties \(\overline{R}\) and \(\overline{Q}\) are actually defined over \(F\) and \(M = F(\mathbb{A}^n)\), respectively, where extensions \(k/F/k_0\) are purely transcendental and \(F/k_0\) is, moreover, finitely generated. By the same reason, we can assume that the geometric object \(\overline{U}\) is defined over \(F\), whereas the correspondence \(\overline{α}\) is defined over \(M\). Therefore, there exist varieties \(R/F\), \(Q/M\), an object \(U\) of \(\mathcal{X}_R \otimes \text{DM}_{\text{gm}}(F; \mathbb{F}_p)\) and a degree one \(M\)-correspondence \(α: Q \sim R_M\) such that \(R|k = \overline{R}\), \(Q|L = \overline{Q}\), \(U|k = \overline{U}\) and \(α|L = \overline{α}\). Note that we still have \(\mathcal{X}_Q \geq \mathcal{X}_{R_M}\) (because \(α\) is defined over \(M\) and by functoriality), and \(U_M \otimes \tilde{\mathcal{X}}_Q = 0\) (because the restriction \(\text{DM}(M; \mathbb{F}_p) \rightarrow \text{DM}(L; \mathbb{F}_p)\) is conservative). But the extension \(M/F\) can be embedded into \(k/F\), making \(k/M\) purely transcendental. Let \(Q'\) be a variety over \(k\) obtained from \(Q\) using this embedding. Then \(\mathcal{X}_{Q'} \geq \mathcal{X}_{\overline{R}}\) (because \(k/M\) is purely transcendental) and \(\overline{U} \otimes \tilde{\mathcal{X}}_{Q'} = 0\) in \(\text{DM}(k; \mathbb{F}_p)\). Hence, \(\overline{U} = 0\) in \(\text{DM}(E/k; \mathbb{F}_p)\).

Using Lemma 2.9.1 our problem is reduced to the case of a finite extension. In this situation, the statement is true for an arbitrary field.

**Lemma 2.9.2.** Let \(E/L\) be a finite extension of fields. Then the functor

\[
\text{DM}(E/L; \mathbb{F}_p) \rightarrow \text{DM}(E/E; \mathbb{F}_p)
\]

is conservative.

**Proof.** Let \(E = L(P)\) for some smooth connected zero-dimensional variety \(P\). Let \(U \in \text{Ob}(\mathcal{X}_P \otimes \text{DM}(L; \mathbb{F}_p))\) be an object vanishing in \(\text{DM}(E/E; \mathbb{F}_p)\). Then, for the disjoint
union $Q$ of all anisotropic varieties over $E$, we have $U_E \otimes \tilde{X}_Q = 0$ in $\text{DM}(E; \mathbb{F}_p)$. Consider a smooth $L$-variety $Q$ given by the composition $Q \to \text{Spec}(E) \to \text{Spec}(L)$. We have a natural map $Q \to Q_E$. This means that $\mathcal{X}_Q \cong \mathcal{X}_{Q_E}$, and thus $U_E \otimes \tilde{X}_{Q_E} = 0$ as well. Clearly, $\mathcal{X}_Q \cong \mathcal{X}_F$. Suppose that these are equal. Then there exists a commutative diagram

$$
\begin{array}{c}
Q \\
\downarrow \\
\text{Spec}(F) \\
\end{array} 
\begin{array}{c}
\text{Spec}(E) \\
\downarrow \\
\text{Spec}(L)
\end{array}
$$

where $F$ is an extension of $E$ of degree prime to $p$. But because $[E:L]$ is finite, the composition $\text{Spec}(F) \to Q \to \text{Spec}(E)$ has the same (prime to $p$) degree. This contradicts the fact that $Q$ is anisotropic. Hence, $\mathcal{X}_Q \cong \mathcal{X}_F$, and so $\mathcal{X}_Q \cong \mathcal{X}_E$, where $Q$ is a disjoint union of all $L$-varieties $Q$ with $\mathcal{X}_Q \cong \mathcal{X}_E$. Thus, $(U \otimes \tilde{X}_Q)_E = 0$ as well. By [14, Theorem 2.3.5], the functor $\mathcal{X}_E \otimes \text{DM}(L; \mathbb{F}_p) \to \text{DM}(E; \mathbb{F}_p)$ is conservative, so $(U \otimes \tilde{X}_Q) \otimes \mathcal{X}_E = 0$ in $\text{DM}(L; \mathbb{F}_p)$. This means that $U = 0$ in $\text{DM}(E/L; \mathbb{F}_p)$. □

This finishes the proof of Proposition 2.9.

Another type of functoriality we have is the following one. Let $k(A)/k$ be a purely transcendental extension of $k$. Then we have a natural functor

$$
\text{DM}(E/k; \mathbb{F}_p) \to \text{DM}(E(A)/k(A); \mathbb{F}_p).
$$

One just needs to observe that the inequality $\mathcal{X}_Q \cong \mathcal{X}_E$ is preserved under the passage from $k$ to $k(A)$.

It is natural to ask: In which situations will our localisation functors be conservative?

**Question 2.10.**

(a) What is the kernel of the collection of functors $\{\varphi_E | E/k \text{ f.g. extension}\}$?

(b) What is the kernel of the collection of functors $\{\psi_E | E/k \text{ f.g. extension}\}$?

Because the passage from $k_0$ to $k = k_0(t_1, t_2, \ldots)$ is conservative and any finitely generated extension $E$ of $k$ has the form $E = E_0(t_N, \ldots)$, for some finitely generated extension $E_0$ of $k_0$, and by Proposition 2.9, the triviality of $\{\varphi_{E_0} | E_0/k_0 \text{ f.g. extension}\}$ on $X_0$ implies the triviality of $\{\psi_{E_0} | E_0/k_0 \text{ f.g. extension}\}$ on $X_0$, implying the triviality of $\{\varphi_E | E/k \text{ f.g. extension}\}$ on $X_0|k$, which, in turn, is equivalent to the triviality of $\{\varphi_E | E/k \text{ f.g. extension}\}$ on $X_0|k$. Thus, for a given geometric object $X_0/k_0$,

$$(a) \Rightarrow (b) \Rightarrow (b)_{\text{flex}} \iff (a)_{\text{flex}},$$

where $(a)$ means that $X_0$ is in the kernel of the family $\{\varphi_{E_0} | E_0/k_0 \text{ f.g. extension}\}$, $(a)_{\text{flex}}$ means that $X_0|k$ (the restriction to the flexible closure) is in the kernel of the family $\{\varphi_E | E/k \text{ f.g. extension}\}$, etc.
Remark 2.11. Restricting the functors $\psi_E$ to the tensor triangulated subcategory $DQM^{gm}$ generated by motives of smooth projective quadrics and specialising it further, one gets the functors of T. Bachmann $\Phi^E : DQM^{gm} \to K^b(Tate(\F_2))$ to the category of bigraded $\F_2$-vector spaces (see [1]). This can be deduced from the fact that the functor $\psi_E$ maps the subcategory $DQM^{gm}$ to the subcategory of geometric Tate motives in $DM(E/E; \F_p)$ (by [17, Proposition 4.9]). The functors $\Phi^E$, constructed originally by completely different methods, were shown by T. Bachmann to be conservative [1, Theorem 31]. In particular, the collection $\{\psi_E| E/k \text{ - f.g. extension}\}$ is conservative on $DQM^{gm}$. Our approach also permits seeing conservativity on this and other similar subcategories. Namely, it follows from [17, Proposition 4.9] that, for any object $A$ of $DQM^{gm}$, there exists a finite filtration by idempotents on the unit object $T$, such that associated graded idempotents map $A$ to geometric Tate motives. And this collection of associated graded idempotents (having a form $\tilde{X}_Q \otimes \mathcal{X}_P$, for some smooth varieties $P$ and $Q$, with $P$-connected) acts conservatively (as the unit object is an extension of them). It remains to observe that, for geometric Tate motives, the triviality of $\tilde{X}_Q \otimes \mathcal{X}_P \otimes A$ is equivalent to the triviality of $TP \otimes A \in Ob(DM(E/E; \F_p))$, for $E = k(P)$. $\triangle$

Remark 2.12. If the ground field $k_0$ is algebraically closed, then there exists only one $\sim$-equivalence class of finitely generated extensions of $k_0$ (the trivial one). Thus, there is only one ‘local’ point and only one localisation functor $\varphi : DM(k_0; \F_p) \to DM(k_0/k_0; \F_p)$, which is an equivalence of categories (because there are no anisotropic varieties over $k_0$). Thus, in this case, the family $\{\varphi_{E_0}| E_0/k_0 \text{ - f.g. extension}\}$ is conservative, but it does not provide any interesting information. $\triangle$

The collection $\{\varphi_E| E/k \text{ - f.g. extension}\}$ is not conservative, in general.

Example 2.13. (1) Let $k$ be a flexible field and $C$ be an elliptic curve over $k$ without complex multiplication. Consider $p = 2$. Then $M(C) = T \oplus \tilde{M}(C) \oplus T(1)[2]$. Consider the Chow groups $\text{Ch}_{Num(p)}$ modulo numerical equivalence with $\F_2$-coefficients (see Subsection 4.2). Then

$$\text{Ch}^1_{Num(p)}(C \times C) = [pt \times C] \cdot \F_2 \oplus [C \times pt] \cdot \F_2.$$ 

Indeed, for an arbitrary $p$, such a group is generated by $[pt \times C], [C \times pt]$ and the class of the diagonal $[\Delta]$ (in the absence of complex multiplication). But with $\F_2$-coefficients, $[\Delta]_p \sim [pt \times C] + [C \times pt]$. Thus, $\tilde{M}(C) = 0$ in $\text{Chow}_{Num}(E; \F_2)$, for any extension $E/k$. Hence, by Theorem 4.11(1), it is zero in $\text{Chow}(E/E; \F_2)$, which is a subcategory of $DM(E/E; \F_2)$. Therefore, all isotropic realisations $\psi_E(\tilde{M}(C))$ are trivial. At the same time, $\tilde{M}(C)$ is nontrivial, because the (complex) topological realisation of it is nontrivial (has nonzero $H^1_{Top}$). Alternatively, one can see that the restriction to the algebraic closure $\tilde{M}(C)|_\overline{\F}$ is nontrivial. Note that the choice of a prime was essential here.

(2) Refining the previous example, we can show that even the combination

$$\{\varphi_E| E/k \text{ - f.g. extension}\} \cup \text{res}_{\overline{\F}}$$

is not conservative on $DM^{gm}(k; \F_2)$. In the above situation, consider some nontrivial quadratic extension $F = k(\sqrt{a})$ and $P = \text{Spec}(F) \to \text{Spec}(k)$. Let $\alpha = \{a\} \in K^M_1(k)/2$
and $\tilde{M}_a$ be the ‘completely’ reduced Rost motive (see the proof of Theorem 3.5). This motive fits into the exact triangle $\tilde{M}_a \rightarrow \tilde{X}_a[1] \rightarrow \tilde{X}_a \rightarrow \tilde{M}_a[1]$, where $\tilde{X}_a = \tilde{X}_P$. Let us show that $U = \tilde{M}(C) \otimes \tilde{X}_a \neq 0$. Indeed, such a triviality is equivalent to the fact that the projection $\chi_P \times \tilde{M}(C) \rightarrow \tilde{M}(C)$ has a section. And because $\tilde{M}(C)$ is a pure motive (= Chow motive), any such section is liftable to a section of $P \times \tilde{M}(C) \rightarrow \tilde{M}(C)$. This would mean that the projector $\rho$ defining $\tilde{M}(C)$ is in the image of the natural map $\pi: \text{Ch}^1(C \times C \times P) \rightarrow \text{Ch}^1(C \times C)$. Note, however, that $\text{Ch}^1(C \times C|_{\tilde{X}}) = [\Delta] \cdot \mathbb{F}_2 \oplus [p t \times C] \cdot \mathbb{F}_2 \oplus [C \times pt] \cdot \mathbb{F}_2$ (because $\tilde{k}$-points of the Jacobian form a 2-divisible group), and so the map $\text{res}_{\tilde{X}} \circ \pi_* : \text{Ch}^1(C \times C \times P) \rightarrow \text{Ch}^1(C \times C|_{\tilde{X}})$ is zero (because the action of the Galois group on $\text{Ch}^1(C \times C|_{\tilde{X}})$ is trivial, which implies that $\text{res}_{\tilde{X}} \circ \pi_* = 2 \cdot \text{res}_{\tilde{k}/F}$). On the other hand, $\rho|_{\tilde{X}} \neq 0$, because it is nonzero even in the topological realisation. Hence, $\rho$ is not in the image of $\text{res}_{\tilde{X}} \circ \pi_*$, and $\tilde{M}(C) \otimes \tilde{X}_a \neq 0$. Notice that $\psi_E(U) = 0$, because $\psi_E(\tilde{M}(C)) = 0$, and $\text{res}_{\tilde{X}}(U) = 0$, because $\text{res}_{\tilde{X}}(\tilde{X}_a) = 0$. Thus, we have produced a nontrivial example on which the needed combination of functors vanishes but, so far, not a geometric one.

Consider $V = \tilde{M}(C) \otimes \tilde{M}_a$. Then we have a distinguished triangle $V \rightarrow U[1] \rightarrow U \rightarrow V[1]$. In particular, $V$ is geometric and all of the above functors vanish on it. It remains to show that $V \neq 0$. Note that because $U \neq 0$, the homology $\text{Hom}_{\text{DM}(E; \mathbb{F}_2)}(T(\ast)[\ast'], U)$ considered for all finitely generated extensions $E/k$ is nontrivial. At the same time, this homology is zero for $\ast' < \ast$ (below the main diagonal). This implies that $V \neq 0$. Indeed, if it were zero, then the homology of $U$ would be [1]-periodic, which is not the case.

2.1. Local Chow motivic category

Let $X$ be a scheme of finite type over $k$. We can define its isotropic Chow groups as

$$\text{Ch}_{k/k; r}(X) := \text{Hom}_{\text{DM}(k/k; \mathbb{F}_p)}(T(r)[2r], M^c(X)),$$

where $M^c(X)$ is the motive with compact support of $X$ (see [20]). For smooth varieties, we have from duality

$$\text{Ch}_{k/k}^*(X) = \text{Hom}_{\text{DM}(k/k; \mathbb{F}_p)}(M(X), T(r)[2r]).$$

The theory $\text{Ch}_{k/k}$ has natural pull-backs and push-forward maps coming from the respective maps between motives of varieties that satisfy all of the axioms of [9, Definition 1.1.2] (because these follow from the properties of motives). Finally, we have the excision axiom (EXCI), claiming that for a scheme $X$ with the closed subscheme $Z$ and open complement $U$, there is an exact sequence

$$\text{Ch}_{k/k; \ast}(Z) \xrightarrow{i_*} \text{Ch}_{k/k; \ast}(X) \xrightarrow{j^*} \text{Ch}_{k/k; \ast}(U) \rightarrow 0.$$

This follows from the Gysin exact triangle [20, (4.1.5)]

$$M_c(Z) \rightarrow M_c(X) \rightarrow M_c(U) \rightarrow M_c(Z)[1]$$

and the fact that the map $\text{Ch}^* \rightarrow \text{Ch}_{k/k}^*$ is surjective, which follows from Proposition 2.16 below. Thus, $\text{Ch}_{k/k}^*$ is an oriented cohomology theory (with excision) on $\text{Sm}_k$ in the sense of [18, Definition 2.1].
Definition 2.14. Let $Q$ be a scheme (of finite type) over $k$ and $n \in \mathbb{N}$. We say that $Q$ is ‘$n$-anisotropic’ if the degrees of all closed points of $Q$ are divisible by $n$.

Schemes that do not have this property will be called not $n$-anisotropic, and we will reserve the term isotropic for a scheme having a zero-cycle of degree 1 (mod $n$). Below almost everywhere we will be dealing with $n = p$-prime, and so isotropic will be the complement to anisotropic. Unless specified, the term anisotropic will mean $p$-anisotropic, for some prime $p$.

Definition 2.15. Let $X$ be a scheme over $k$, and $x \in \text{Ch}_r(X)$. We call $x$ ‘anisotropic’ if there exists a proper morphism $f : Y \to X$ from a $p$-anisotropic scheme $Y$ and a class $y \in \text{Ch}_r(Y)$ such that $x = f_*(y)$.

For fields of characteristic zero and $X$ projective, $x$ is anisotropic if and only if it is a push-forward of the generic cycle from some smooth projective anisotropic variety over $k$.

Isotropic Chow groups can be alternatively described as follows.

Proposition 2.16. 

$$\text{Ch}_{k/k}(X) = \text{Ch}(X)/(\text{anisotropic classes}).$$

Proof. By Proposition 2.6, $\text{Hom}_{DM(k/k; \mathbb{F}_p)}(T(r)[2r].M^c(X))$ is the colimit of the groups $\text{Hom}_{DM(k/k; \mathbb{F}_p)}(\tilde{X}_Q(r)[2r].M^c(X) \otimes \tilde{X}_Q)$, where $Q$ runs over all anisotropic varieties over $k$. Recall that we have an exact triangle

$$\begin{array}{ccc}
\mathcal{X}_Q & \longrightarrow & T \\
\longrightarrow & & \longrightarrow \\
\longrightarrow & & \longrightarrow \tilde{X}_Q & X_Q [1].
\end{array}$$

By [14, Theorem 2.3.2] (which is basically [19, Lemma 4.9]), $\text{Hom}_{DM(k/k; \mathbb{F}_p)}(\mathcal{X}_Q(*)[*'], M^c(X) \otimes \tilde{X}_Q) = \text{Coker}(\text{Ch}_r(X \times Q) \xrightarrow{\pi_Q^*} \text{Ch}_r(X))$. Thus, $\text{Hom}_{DM(k/k; \mathbb{F}_p)}(T(r)[2r], M^c(X)) = \text{Ch}_r(X)/I$, where $I$ is the subgroup generated by the images of $(\pi_Q)_*$, for all anisotropic varieties $Q/k$. In other words, we mod-out all anisotropic classes. 

The isotropic motivic category $\text{DM}_{gm}(k/k; \mathbb{F}_p)$ has a pure part.

Definition 2.17. Define the ‘isotropic Chow motivic category’ $\text{Chow}(k/k, \mathbb{F}_p)$ as the full additive subcategory of $\text{DM}_{gm}(k/k; \mathbb{F}_p)$ - the image of $\text{Chow}(k, \mathbb{F}_p)$ under the natural projection

$$\text{DM}_{gm}(k, \mathbb{F}_p) \to \text{DM}_{gm}(k/k, \mathbb{F}_p).$$

Thus, the objects of $\text{Chow}(k/k, \mathbb{F}_p)$ can be identified with direct summands of motives of smooth projective varieties over $k$, and the morphisms are described as follows.
Proposition 2.18. Let $X$ and $Y$ be smooth projective $k$-varieties. Then

$$\text{Hom}_{\text{Chow}(k/k, F_p)}(M(X), M(Y)) = \text{Ch}^{\dim(Y)}_{k/k}(X \times Y).$$

Proof. If $B$ is an object of $\text{DM}_{gm}(k; F_p)$ with the dual $B^\vee$, and $A, C$ are objects of $\text{DM}(k; F_p)$, then we have a functorial identification

$$\text{Hom}_{\text{DM}(k; F_p)}(A \otimes B, C) = \text{Hom}_{\text{DM}(k; F_p)}(A, B^\vee \otimes C).$$

Hence, for the projector $\rho_Q = \tilde{\chi}_Q \otimes$ we also have a functorial identification

$$\text{Hom}_{\text{DM}(k; F_p)}(\rho_Q(A) \otimes \rho_Q(B), \rho_Q(C)) = \text{Hom}_{\text{DM}(k; F_p)}(\rho_Q(A), \rho_Q(B^\vee) \otimes \rho_Q(C)).$$

Taking into account that $M(X)^\vee = M(X)(-d)[-2d]$, where $d = \dim(X)$, we obtain that

$$\text{Hom}_{\text{Chow}(k/k, F_p)}(M(X), M(Y)) = \text{Hom}_{\text{DM}(k; F_p)}(T(d)[2d], M(X \times Y))$$

$$= \text{Ch}^{\dim(Y)}_{k/k}(X \times Y).$$

We can describe Chow motives disappearing in the isotropic category.

Remark 2.19. An object $U$ of $\text{Chow}(k, F_p)$ vanishes in $\text{Chow}(k/k, F_p)$ if and only if it is a direct summand in the motive of a (smooth projective) anisotropic variety.\footnote{I am grateful to T. Bachmann for emphasizing this.} Indeed, a direct summand $U$ of $M(P)$ vanishes in $\text{Chow}(k/k, F_p)$ if and only if the identity map $\text{id}_U : U \to U$ does. By Propositions 2.16 and 2.18, this means that the map $\Delta_U : T \to U \otimes U^\vee$ factors through (the motive of) a smooth projective anisotropic variety $Q$. Consequently, $U$ is a direct summand of $M(Q) \otimes U$, which, in turn, is a direct summand of $M(Q \times P)$, and the latter variety is still anisotropic.

From Propositions 2.16 and 2.18 we obtain the following.

Corollary 2.20. The functor $\text{Chow}(k, F/p) \to \text{Chow}(k/k, F/p)$ is surjective on morphisms.

In other words, all ‘local’ morphisms between (isotropic) Chow motives are defined ‘globally’.

We will have a closer look at the category $\text{Chow}(k/k, F_p)$ in Section 4.

3. Local motivic cohomology of a point

In this section we will compute the motivic cohomology of a point in the isotropic motivic category for $p = 2$. This will be achieved by substituting all anisotropic $k$-varieties in the colimit of Proposition 2.6 by norm-varieties for nonzero pure symbols from $K_4^M(k)/2$ (anisotropic Pfister quadrics, in our case). This makes the problem amenable to calculation due to Voevodsky technique. Moreover, the resulting answer, drastically different from the ‘global’ one, in turn sheds some light on this technique.
The starting point is the following statement, which is a slight modification of the result of J.-L. Colliot-Thélène and M. Levine [4, Theorem 3]. We provide a somewhat different proof.

**Statement 3.1.** Let $B$ be an anisotropic $(\text{mod } n)$ projective variety. Then, over some finitely generated purely transcendental extension, it can be embedded into an anisotropic hypersurface of degree $n$.

**Proof.** Embed $B$ into a projective space. Passing to a Veronese embedding, we can assume that all of the relations in the projective coordinate ring of $B$ are generated by quadratic ones or, in other words, that $B$ is defined by quadrics. Then it will also be defined by hypersurfaces of degree $n$ (in our $\mathbb{P}^m$), for any $n \geq 2$. Let $\mathbb{P}^r = \text{Proj}|D|$ be the projective system of hypersurfaces of degree $n$ containing $B$. I claim that the generic element of this linear system is an anisotropic hypersurface. Consider $Y \subset (\mathbb{P}^m \setminus B) \times \mathbb{P}^r$ defined by $Y = \{(x, H)|x \in H\}$. Then $Y$ is a projective bundle $\text{Proj}_{(\mathbb{P}^m \setminus B)}(V)$ over $(\mathbb{P}^m \setminus B)$, where $V$ is a codimension 1 subbundle in the trivial bundle $|D|$. Let $Y_\eta$ be the generic fibre of the projection $Y \to \mathbb{P}^r$. This is exactly $(Q_\eta \setminus B)$, where $Q_\eta$ is the generic hypersurface of degree $n$ passing through $B$. Note that the degree $(\text{mod } n)$ is well defined on the zero-cycles on $Y_\eta$, because $B$ is anisotropic. By the projective bundle theorem, $\text{CH}^*(Y)$ is a free module over $\text{CH}^*(\mathbb{P}^m \setminus B)$ with the basis $1, \rho, \ldots, \rho^{r-1}$, where $\rho = c_1(O(1))$. On the other hand, we have a surjective ring homomorphism $\text{CH}^*(Y) \to \text{CH}^*(Y_\eta)$ that is zero on $\rho$ (because this class is supported on a hypersurface in $\mathbb{P}^r$). Thus, we obtain the surjective map $\text{CH}^*(\mathbb{P}^m \setminus B) \to \text{CH}^*(Y_\eta)$, which sends the class $c \in \text{CH}^*(\mathbb{P}^m \setminus B)$ to the restriction of $\pi^*(c)$ to $Y_\eta$, where $\pi$ is our projective bundle fibration. In particular, $c \in \text{CH}_1(\mathbb{P}^m \setminus B)$ is mapped to a zero-cycle on $Y_\eta$ whose degree is equal to the intersection number of $c$ and any hypersurface from our linear system (which, again, makes sense, because $B$ is anisotropic). Hence, it is a zero-cycle of degree $0$ $(\text{mod } n)$. Thus, the degrees of all zero-cycles on $Y_\eta$ are divisible by $n$, and so the same is true about $Q_\eta = Y_\eta \cup B$.

**Corollary 3.2.** Let $k$ be a flexible field, $U \in \text{Ob}(\text{DM}_{gm}(k; \mathbb{F}_p))$ and $V \in \text{Ob}(\text{DM}(k; \mathbb{F}_p))$. Then

$$\text{Hom}_{\text{DM}(k; \mathbb{F}_p)}(U, V) = \colim_{Q} \text{Hom}_{\tilde{\mathcal{X}}_Q \otimes \text{DM}(k; \mathbb{F}_p)}(U, V),$$

where the colimit is taken over all of the functors $\otimes \tilde{\mathcal{X}}_Q$, where $Q$ runs over all anisotropic hypersurfaces of degree $p$ over $k$. This system is directed.

**Proof.** Let $B$ be any anisotropic variety over $k$. By Statement 3.1, there exists a purely transcendental field extension $E/k$ and anisotropic hypersurface $Q$ over $E$ such that $\mathcal{X}_B|_E \geq \mathcal{X}_Q$. Let $k = k_0(\mathbb{P}^\infty)$. Then there exists a diagram of purely transcendental extensions of fields.
Corollary 3.3. Let \( k \) be a flexible field and \( p = 2 \). Let \( U \in \text{Ob}(\text{DM}_{gm}(k; \mathbb{F}_p)) \) and \( V \in \text{Ob}(\text{DM}(k; \mathbb{F}_p)) \). Then

\[
\text{Hom}_{\text{DM}(k; \mathbb{F}_p)}(U, V) = \text{colim} \text{Hom}_{\mathbb{F}_Q \otimes \text{DM}(k; \mathbb{F}_p)}(U, V),
\]

where the colimit is taken over all of the functors \( \otimes \mathbb{F}_Q \), where \( \alpha \) runs over all nonzero pure symbols from \( K_*^M(k)/2 \) and \( Q_\alpha \) is the respective Pfister quadric. This is a directed system.

Proof. By [15, Corollary 3] (see also [8]), every anisotropic quadric \( Q \) (over any field \( k \)) can be embedded into an anisotropic Pfister quadric \( Q_\alpha \) over an appropriate purely transcendental extension of finite transcendence degree. If now \( k \) is flexible, then arguing as in the proof of Corollary 3.2, we can embed \( Q \) into some anisotropic Pfister quadric \( Q_\alpha' \) over \( k \). Thus, the set of anisotropic Pfister quadrics forms a final subsystem in the system of all anisotropic varieties over a flexible field, which, again, must be directed. \( \square \)

From the fact that the system in Corollary 3.3 is directed, as a by-product, we obtain the following result (which, of course, is a simple consequence of Statement 3.1 and [15, Corollary 3] and can be even seen from the latter result alone).

Proposition 3.4. Let \( k \) be a flexible field and \( \{\alpha_i\}_{i \in I} \) be a finite collection of nonzero pure symbols from \( K_*^M(k)/2 \). Then there exists a nonzero pure symbol \( \alpha \in K_*^M(k)/2 \) divisible by every \( \alpha_i \).

Using Corollary 3.3, we can compute the cohomology of a point in isotropic motivic category for \( p = 2 \). For a nonzero pure symbol \( \alpha \in K_*^M(k)/2 \), let us denote as \( \text{DM}(\mathbb{A}/k; \mathbb{F}_2) \) the full triangulated subcategory \( \mathbb{X}_\alpha \otimes \text{DM}(k; \mathbb{F}_2) \), where \( \mathbb{X}_\alpha = \mathbb{X}_{Q_\alpha} \) and \( Q_\alpha \) is the respective Pfister quadric. Homs between Tate objects in this category can be computed as follows.

Define an \( \mathbb{F}_2 \)-vector space \( Q^{-1}(n) = \oplus_I r_I \cdot \mathbb{F}_2 \), where \( I \) runs over all subsets of \( \pi = \{0, 1, \ldots, n\} \), with the structure of a module over Milnor’s operations \( Q_i \) defined by \( Q_i(r_I) = r_{I \setminus i} \), if \( i \in I \), and zero otherwise, and with the bidegree of \( r_\emptyset \) being \((0)[0]\). Let \( r_{\{n+1\}} \) be a polynomial generator with \( Q_{n+1}(r_{\{n+1\}}) = r_\emptyset \) and \( Q_i(r_{\{n+1\}}) = 0 \), for \( i \neq n+1 \).
Let $R_a$ be a module over $K^M_a(k)/2$ isomorphic to the principal ideal $\alpha \cdot K^M_a(k)/2$ with the generator in bidegree $(0|0)$. In other words, $R_a = K^M_a(k)/\text{Ker}(-\alpha)$. In particular, it has a natural ring structure. The multiplicative structure on $\mathcal{Q}^{-1}(n)[\tau_{n+1}] \otimes \mathbb{F}_2 R_a$ is provided by $\tau_i = \prod \tau_{i_1}$ and the identity $\tau_i^2 = \tau_{i+1} \cdot \rho$, for $0 \leq i \leq n$, and $\rho = \{-1\}$. In other words, this is the ring $R_a[\tau_i]_{0 \leq i \leq n+1}/(\tau_i^2 - \tau_{i+1} \cdot \rho | 0 \leq i \leq n)$.

For a motivic category $D$ with Tate objects, let us denote as $\text{End}_D(V)$ the ring $\oplus_{a,b} \text{Hom}_D(V, V(a)b)$.

**Theorem 3.5.** Let $\alpha \in K^M_m(k)/2$ be a nonzero pure symbol. Then

$$\text{End}_{\text{DM}(\mathbb{A}/k; \mathbb{F}_2)}(T) = \mathcal{Q}^{-1}(m-2)[\tau_{m-1}] \otimes \mathbb{F}_2 R_a[\tau_i]_{0 \leq i \leq m-1}/(\tau_i^2 - \tau_{i+1} \cdot \rho | 0 \leq i \leq m-2).$$

**Proof.** By definition, $\text{End}_{\text{DM}(\mathbb{A}/k; \mathbb{F}_2)}(T) = \text{End}_{\text{DM}(k; \mathbb{F}_2)}(\tilde{X}_a)$. From this point, all of the Hom will be in the category $\text{DM}(k; \mathbb{F}_2)$, unless specified otherwise, so I will omit it from notations.

Let $M_a$ be the respective Rost motive [12]. We have natural maps $T(d)[2d] \to M_a \to T$, where $d = 2^{m-1} - 1$, whose composition is zero. Cutting out the respective Tate motives from $M_a$ and tensoring the result by $\mathcal{X}_a$ and $\tilde{\mathcal{X}}_a$, respectively, we obtain

$$\xymatrix{ \mathcal{X}_a \ar[r]^\mu \ar[d]^{|1|} & \tilde{\mathcal{X}}_a \ar[d]^{|1|} \\
\tilde{X}_a(d)[2d] & \tilde{M}_a \\
\mathcal{X}_a(d)[2d] & \mathcal{M}_a \ar[l]_{|1|} \ar[u]^{|1|} }$$

Here we are using the fact that $M_a \otimes \tilde{\mathcal{X}}_a = 0$ and that $\tilde{M}_a \otimes \mathcal{X}_a = 0$, which are equivalent to the exactness of the left triangle [22, Theorem 4.4]. Let us denote the above half of the octahedron as $\Diamond$. Note that because there are no Homs from $\mathcal{X}_a$ to $\tilde{\mathcal{X}}_a(*)[*']$, we can naturally identify groups $\text{Hom}(\tilde{\mathcal{X}}_a, \tilde{\mathcal{X}}_a(*)[*']) = \text{Hom}(T, \tilde{\mathcal{X}}_a(*)[*'])$.

For each $0 \leq i < m-1$, let $\beta \in K^M_{i+1}(k)/2$ be any pure symbol dividing $\alpha$. We obtain a similar map $\eta_\beta(-d_i)[-2d_i] : \tilde{\mathcal{X}}_\beta \to \tilde{\mathcal{X}}_\beta(-d_i)[-2d_i-1]$, where $d_i = 2^i - 1$. Tensoring it with $\tilde{\mathcal{X}}_a$, we obtain the map $\eta_{i|1} : \tilde{\mathcal{X}}_\beta \to \tilde{\mathcal{X}}_a(-d_i)[-2d_i-1]$ or, in other words, an element $\eta_{i|1} \in \text{Hom}_{\text{DM}(\mathbb{A}/k; \mathbb{F}_2)}(T, T(-d_i)[-2d_i - 1])$. Below we will see that this map does not depend on the choice of the divisor $\beta$.

For any smooth projective $R$, we have the natural (homological) action of the Steenrod algebra on $\text{Hom}(T, \tilde{\mathcal{X}}_R(*)[*'])$ and the natural (cohomological) action of it on $\text{Hom}(\tilde{\mathcal{X}}_R, T(*)[*'])$, which commute with the maps $\tilde{\mathcal{X}}_R \to \tilde{\mathcal{X}}_S$ (for $\mathcal{X}_R \geq \mathcal{X}_S$). In particular, we have the action of the Milnor’s operations $Q_i$. If $R$ is a $v_i$-variety, then by the arguments of V. Voevodsky [22, Corollary 3.8], the differential $Q_i$ is exact on $\text{Hom}(\tilde{\mathcal{X}}_R, T(*)[*'])$. By the same arguments, it is exact on $\text{Hom}(T, \tilde{\mathcal{X}}_R(*)[*'])$. In particular, in our case, $Q_i$ is exact on $\text{Hom}(T, \tilde{\mathcal{X}}_a(*)[*'])$ and $\text{Hom}(\tilde{\mathcal{X}}_a, T(*)[*'])$, for any $i \leq m-1$.

Consider $N = \oplus \text{Hom}(\tilde{\mathcal{X}}_a[-1], \mathcal{X}_a(*)[*'])$. It has the natural right action of $A = \text{End}(\tilde{\mathcal{X}}_a)$ as well as the left action of $A = \text{End}(\mathcal{X}_a)$. In particular, there is a right action by $\eta$.
and a left one by $\mu$. I claim that these are mutually inverse. Indeed, to see that for any $f : \tilde{\mathcal{X}}_a \to \mathcal{X}_a(a)[b]$, one has $\mu \circ f \circ \eta = f$, it is sufficient to look at the ‘vertical axis’ of $\mathcal{X}_a(a)[b]$.

Thus, $N$ is $\mu - \eta$-periodic, because the actions by $\mu$ and $\eta$ are mutually inverse isomorphisms on $N$.

At the same time, $\text{Hom}(\tilde{\mathcal{X}}_a, \tilde{\mathcal{X}}_a(a)[b]) = \text{Hom}(T, \tilde{\mathcal{X}}_a(a)[b])$ is zero for $b > a$, and $\text{Hom}(\tilde{\mathcal{X}}_a, T(a)[b]) = 0$ for $b \leq a + 1$ by the Beilinson-Lichtenbaum ‘conjecture’ (note that $\tilde{\mathcal{X}}_a$ disappears in the etale topology). Considering $\text{Hom}$ from $\tilde{\mathcal{X}}_a[-1]$ to the $(a)[b]$-shifted exact triangle $\mathcal{X}_a \to T \to \tilde{\mathcal{X}}_a \to \mathcal{X}_a[1]$, we obtain that $\tilde{\mathcal{X}}_a$ is exactly the $\leq 0$ diagonal part of $N$, and $H^s_{\mathcal{X}_a}(\tilde{\mathcal{X}}_a[-1]; \mathbb{F}_2)$ is exactly the $> 0$ diagonal part of it. Thus, $N$ combines the homology and cohomology groups of $\tilde{\mathcal{X}}_a$.

Because there are no Hom from $T$ to $\mathcal{X}_a(a)[a + 1]$, the map $\text{Hom}(T, \mathcal{X}_a(a)[a]) \to \text{Hom}(T, \tilde{\mathcal{X}}_a(a)[a])$ is surjective, so the 0th diagonal of $\tilde{\mathcal{X}}_a$ (or the 0th diagonal of $N$, which is the same) as a $K^s_{*}(k)/2$-module is generated by 1 - the unit of this ring. Let $R_a$ be this 0th diagonal. From $\mu - \eta$-periodicity, the diagonal number $(-2^{m-1})$ (where $\eta$ resides), as a $K^s_{*}(k)/2$-module, is generated by $\eta$. Because the differential $Q_{m-1}$ is exact on $\tilde{\mathcal{X}}_a$, we obtain that 1 is covered by the image of $Q_{m-1}$ (because $\tilde{\mathcal{X}}_a$ is concentrated in nonpositive diagonals). But the only nonzero element of the needed bidegree is $\eta$. Thus, $Q_{m-1}(\eta) = 1$. Applying the same arguments to the symbol $\beta$ (considered above), we obtain that $Q_{i}(\eta_{\beta}) = 1$, so $Q_{i}(r_{|i|}) = 1$.

For any $I \subset (m - 2)$, denote $r_I := \prod_{i \in I} r_{|i|}$ and $Q_I = \sigma_{i \in I} Q_i$. Denote as $D_j$ the $j$th diagonal of $N$. For $0 \leq i \leq m - 2$, let $I_i = \{ i, i + 1, \ldots, m - 2 \}$. Because $H^s_{\mathcal{X}_a}(\tilde{\mathcal{X}}_a[-1]; \mathbb{F}_2)$ is trivial below the first diagonal, and $Q_i$s are exact, the composition $Q_I : D_2 \to D_{2m-1}$ is injective. But from $\mu - \eta$-periodicity, $D_{2m-1}$ as a $K^s_{*}(k)/2$-module is generated by $\mu$. In particular, the $D_{2i}$ is trivial below $\mu \circ 1 \bullet r_{I_i}$. By the $\mu - \eta$-periodicity, $D_{2i-2m-1}$ is trivial below $r_{I_i}$. In particular, $Q_i(\eta) = 0$, for any $0 \leq i \leq m - 2$ (because this element is below $r_{I_i}$), and because $\eta$ generates $D_{2m-1}$, all of the differentials $Q_i$, for $i \leq m - 2$, are trivial on this diagonal. Applying the same arguments to the divisor $\beta$ of degree $(i + 1)$, we obtain that $Q_{i}(\eta_{\beta}) = 0$ and, hence, $Q_{i}(r_{|i|}) = 0$, for $l < i$ (the fact that $Q_{i}(r_{|i|}) = 0$, for $l > i$, is obvious, because $\tilde{\mathcal{X}}_a$ is concentrated in nonpositive diagonals). Combining it with the (external) co-multiplication identity for Milnor’s operations,

$$Q_K(x \times y) = \sum_{2^I + 2^J = 2^K} Q_I(x) \times Q_J(y) \cdot (-1)^{|I| + |J| - |K|},$$

where $2^I = \sum_{i \in I} 2^i$, we obtain that $Q_I(r_I) = 1$, for any $I \subset (m - 2)$.

Let us show that $D_{-2^I}$ is a free module over $D_0 = R_a$ generated by $r_I$. Let $s$ be the smallest element of $I$ (which we assume to be $m - 1$, if $I$ is empty). Decreasing induction
on $s$. The (base) $s = m - 1$ follows from $\mu - \eta$-periodicity. The, (step): let $2^I = 2^I + 2^s$. Because $I \backslash s$ and $J$ consist of elements larger than $s$, by inductive assumption, $D_{-(2^I + 2^s)} = r_J \cdot D_0$ and $D_{-(2^I - 2^s)} = r_{I \backslash s} \cdot D_0$ (where we denote $r_{[m - 1]} := \eta$). In particular, $Q_s$ is trivial on $D_{-(2^I + 2^s)}$, and from the exact sequence $D_{-(2^I + 2^s)} \xrightarrow{Q_s} D_{-2^I} \xrightarrow{Q_s} D_{-(2^I - 2^s)}$, taking into account that $Q_s(r_J) = r_{I \backslash s}$, we see that $Q_s : D_{-2^I} \xrightarrow{\cong} D_{-(2^I - 2^s)}$ is an isomorphism inverse to the multiplication by $r_s$. Thus, $D_{-2^I} = r_J \cdot D_0$.

From $\mu - \eta$-periodicity we obtain that $\tilde{A}$ is a free module over $R_\alpha$ generated by $\eta^k \cdot r_I$, for $k \geq 0$ and $I \subset (m - 2)$, and $H^{s,s'}_M(\tilde{X}_\alpha[-1]; \mathbb{F}_2)$ is a free module over $R_\alpha$ generated by $\mu^l \cdot r_I$, for $l > 0$ and $I \subset (m - 2)$. Consider $\gamma = \mu \cdot 1 \cdot r_{(m-2)}$, the generator of $D_1$ – the diagonal in the motivic cohomology of $\tilde{X}_\alpha[-1]$, which is the same. By the Beilinson-Lichtenbaum conjecture, multiplication by $\tau$ identifies $D_1$ with the kernel $\text{Ker}(K^M_s(k)/2 \to K^M_s(k(Q_\alpha))/2)$ (see [19, Lemma 6.4]). The generator $\gamma$ is identified with some element of degree $m$, which must coincide with the symbol $\alpha$ (because $\alpha$ vanishes over $k(Q_\alpha)$ and there exists exactly one nonzero element of the respective degree in $D_1$). Hence, as a $K^M_s(k)/2$-module, $R_\alpha$ can be identified with the principal ideal of $K^M_s(k)/2$ generated by $\alpha$. So, as a ring, $R_\alpha = (K^M_s(k)/2)/(\text{Ker}(\alpha))$.

This gives the description of $\tilde{A}$ (as well as $N$) as a module over $K^M_s(k)/2$ and over Steenrod algebra. Finally, the equation $r_i^2 = r_{[i+1]} \cdot \rho$ follows from the co-multiplication identity for Milnor’s operations (1).

As a by-product, we obtain the description of motivic cohomology of $\tilde{X}_\alpha$ (known already from the original version of [10] and [23, Theorem 5.8]) but now enhanced with the structure of a module over motivic homology of $\tilde{X}_\alpha$.

**Corollary 3.6.** Let $\alpha \in K^M_m(k)/2$ be a nonzero pure symbol. As a module over $\tilde{A} = \text{End}_{DM(k; \mathbb{F}_2)}(\tilde{X}_\alpha)$,

$$H^{s,s'}_M(\tilde{X}_\alpha[-1]; \mathbb{F}_2) = \tilde{A}[r_{[m-1]}^{-1}] / \tilde{A}.$$  

It is a free $R_\alpha$-module with the basis $r_{[m-1]}^{-l} \cdot r_I$, for $l > 0$ and $I \subset (m - 2)$.

Now we can compute the ‘local’ motivic cohomology $H^{s,s'}_M(k/k; F_2) = \text{End}_{DM(k; \mathbb{F}_2)}(T)$.

**Theorem 3.7.** Let $k$ be a flexible field. Then

$$H^{s,s'}_M(k/k; F_2) = \mathcal{Q}^{-1}(\infty) = \Lambda_{\mathbb{F}_2(\eta_1)}(1).$$

**Proof.** As we know, our colimit (from Corollary 3.3) is taken over a directed system.

Let $\alpha \in K^M_m(k)/2$ and $\beta = \alpha \cdot [b] \in K^M_{m+1}(k)/2$ be nonzero pure symbols. Consider the restriction

$$\text{End}_{DM(k/k; \mathbb{F}_2)}(T) \xrightarrow{\text{res}} \text{End}_{DM(k/k; \mathbb{F}_2)}(T).$$

Then res = $\tilde{X}_\beta \otimes$ is a ring homomorphism respecting Steenrod algebra action and, in the notations of Theorem 3.5, for $I \subset \{0, \ldots, m - 2\}$, we have $\text{res}(r_I) = r_I$ and $\text{res}(r_{[m-1]} \cdot r_I) = r_{I \cup [m-1]}$. Indeed, res sends $r_0$ to $r_\eta$, and $r_I$ and $r_I$ (respectively $r_{[m-1]} \cdot r_I$ and $r_{I \cup [m-1]}$ are
the only elements (in the source and the target) that are mapped to \( r_\beta \) via \( Q_I \) (respectively, \( Q_{I, (m-1)} \)). In addition, \( res : R_\alpha \to R_\beta \) is the natural projection, corresponding to the map \( \alpha \cdot K^*_M(k)/2 \to \beta \cdot K^*_M(k)/2 \).

Combining this with Corollary 3.3, we obtain that

\[
H^{*,*'}_M(k/k; F_2) = Q^{-1}(\infty) \otimes_{F_2} (K^*_M(k)/2)/N,
\]

where \( N = \bigcup_\alpha \ker(\alpha) \), where \( \alpha \) runs over all nonzero pure symbols in \( K^*_M(k)/2 \). It remains to observe that \( N \) contains \( K^*_M(k)/2 \). Indeed, let \( \{a\} \in K^*_M(k)/2 \) be any element such that \( \{a\} \neq 0 \neq \{-a\} \). Then, from \( \{a, -a\} = 0 \), both \( \{a\} \) and \( \{-a\} \) belong to \( N \). This implies that \( \{-1\} \in N \). Because over a flexible field an element \( a \) as above always exists, we obtain that \( N \) contains \( K^*_M(k)/2 \) and thus coincides with the augmentation ideal \( K^*_M(k)/2 \). Hence, \( (K^*_M(k)/2)/N = F_2 \).

Finally, from the equation \( r_2^{(i)} = r_{(i+1)} \cdot \rho \) it follows that \( r_2^{(i)} = 0 \). Thus, we obtain the external algebra in \( r^{(i)} \) over \( F_2 \).

What is remarkable here is that the Milnor operations are intertwined into the very fabric of the local motivic category. In addition, all of the nonzero elements of \( H^{*,*'}_M(k/k; F_2) \) are ‘rigid’ in the sense that the identity map of the unit object of the local category can be obtained from any such element using Milnor’s operations, so these classes disappear only together with the category itself.

We can now compare ‘local’ and ‘global’ motivic cohomology of a point.
Our ring generators $r_{[i]}$ are related by the action of the Steenrod algebra. Namely, because (modulo $\rho = \{-1\}$), $Q_{i+1} = [Q_i, \text{Sq}^{2i+1}]$ [21] and $\rho$ disappears locally, we obtain from bidegree considerations that $\text{Sq}^{2i} (r_{[i+1]}) = r_{[i]}$. In particular, $\text{Sq}^1 \text{Sq}^2 \ldots \text{Sq}^{2i} r_{[i]} = r_{[i]}$.

**Remark 3.8.** Despite some similarities between the (complex) topological realisation functor and isotropic functors, there is a difference in the way they handle $\tau$. Namely, $\tau_{Top} = 1$, and $\psi_E(\tau) = 0$ (in the case of a flexible field).

The only obstacle that prevents us from performing the same calculations for odd primes is the lack of the analogue of [15, Corollary 3] in this situation. In particular, it would be sufficient to have a positive answer to the following.

**Question 3.9.** Let $Q$ be an anisotropic hypersurface of degree $p$ over $k$. Is it true that, over some finitely generated purely transcendental extension $E/k$, the kernel

$$\text{Ker}(K^M_* (E)/p \to K^M_* (E(Q))/p)$$

contains a nonzero pure symbol?

4. Isotropic category of Chow motives

In this section we will study in detail local Chow motives. As we will see, over a flexible field, these resemble in many respects their topological counterparts and are closely related to the numerical equivalence of cycles with finite coefficients. In particular, the $\text{Hom}$s between such local pure motives are expected to be not larger than $\text{Hom}$s between their topological realisations and so finite-dimensional. We will prove this in various situations.

Let us start by introducing some ‘gradual’ approach to the numerical equivalence of cycles, which will permit measuring our progress towards the goal.

4.1. Theories of higher types and numerical equivalence

Let $A$ be a commutative ring and $\mathbb{L} \xrightarrow{\varphi} A$ be some formal group law with $A$-coefficients. Denote as $A^*_{(0)} := \Omega^* \otimes_{\mathbb{L}} A$ the respective free theory in the sense of Levine-Morel [9, Remark 2.4.14]. By [18, Proposition 4.7] this is a theory of rational type. We call this type 0. We are going to introduce the theory $A^*_{(n)}$ of type $n$ as some quotient of $A^*_{(0)}$. This is based on the following construction (cf. [6, Example 4.6]):

**Example 4.1.** Let $A^*$ be some oriented cohomology theory (with localisation) in the sense of [18, Definition 2.1] and $\Gamma = \{Q_\lambda, a_\lambda\}_{\lambda \in \Lambda}$ be a collection of smooth projective $k$-varieties with some classes $a_\lambda \in A^*(Q_\lambda)$. That is, we have a collection of $A^*$-correspondences $\rho_\lambda : Q_\lambda \rightsquigarrow \text{Spec}(k)$. Construct the new theory $A^*_{(n)}$ as follows:

$$A^*_{(n)}(X) := A^*(X)/(im((\rho_\lambda \times id)_s)_{\lambda \in \Lambda}),$$

where $\rho_\lambda \times id$ is the correspondence $Q_\lambda \times X \rightsquigarrow X$. In other words, we mod-out all of the elements of the form $\beta_\alpha (a_\lambda \cdot u)$, where $u$ is an arbitrary element of $A^*(Q_\lambda \times X)$ and $\alpha$
and β are natural projections:

\[ Q_\lambda \leftarrow^\alpha Q_\lambda \times X \rightarrow^\beta X. \]

One can check that the resulting theory \( A^*_\gamma \) will be an oriented cohomology theory in the sense of [18, Definition 2.1] \( \Delta \).

**Definition 4.2.** Let \( Q \xrightarrow{\pi} \text{Spec}(k) \) be a smooth projective variety and \( a \in A^*(Q) \). We say that \( a \sim 0 \) if \( \pi_*(a \cdot b) = 0 \), for any \( b \in A^*(Q) \).

Now we can introduce the theories of higher types.

**Definition 4.3.** Consider the collection \( \Gamma_n = \{Q_\lambda, a_\lambda\}_{\lambda \in \Lambda} \), where \( Q_\lambda \) runs through all smooth projective \( k \)-varieties of dimension \( 2n - 1 \) and \( a_\lambda \in A^*(Q_\lambda) \) runs over all elements \( \sim 0 \). Define

\[ A^*_n := (A^*_{(0)})_{\Gamma_n}^\Delta. \]

If \( a \in A^*(Q) \) is \( \sim 0 \), then \( a \times [(\mathbb{P}^1)] \in A^*(Q \times (\mathbb{P}^1)^2) \) is also \( \sim 0 \). Therefore, the images of correspondences from \( \Gamma_n \) are covered by those from \( \Gamma_{n+1} \). Hence, we get a chain of surjections

\[ A^*_0 \rightarrow A^*_1 \rightarrow A^*_2 \rightarrow \ldots \rightarrow A^*_n \rightarrow \ldots \]

with the colimit \( A^*_\text{Num} \). Here \( A^*_\text{Num} \) is obtained from \( A^* \) by moding-out all classes \( \sim 0 \) on all varieties.

**Remark 4.4.** For \( n = 1 \), the theory \( A^*_{(1)} \) is, by definition, the algebraic version \( A^*_{\text{alg}} \). In particular, \( \text{CH}^*_{(1)} = \text{CH}^*_{\text{alg}} \) \( \Delta \).

The meaning of the theory \( A^*_\text{Num} \) is described by the following universal property.

**Proposition 4.5.** For any oriented generically constant cohomology theory (with localisation) \( \widetilde{A}^* \) (in the sense of [18, Definition 2.1] and [9, Definition 4.4.1]) with the formal group law \( \mathbb{L} \xrightarrow{\varphi} A \), there exists a unique morphism of theories \( \widetilde{A}^* \rightarrow A^*_\text{Num} \) that is surjective.

**Proof.** By [18, Proposition 4.8], the canonical morphism of theories \( G : A^*_0 \rightarrow \widetilde{A}^* \) is surjective (this morphism is induced by the canonical morphism \( \Omega^* \rightarrow \widetilde{A}^* \) of [9, Theorem 1.2.6]). By the same universality of algebraic cobordism, such morphism is unique. In particular, there is a unique morphism of theories \( A^*_0 \rightarrow A^*_\text{Num} \). Note that \( G|_{\text{Spec}(k)} : A \xrightarrow{\sim} A \) is an isomorphism. Hence, if \( x \in A^*_0(X) \) belongs to the kernel of \( G \), then \( x \sim 0 \). Thus, the unique morphism of theories \( A^*_0 \rightarrow A^*_\text{Num} \) factors through \( \widetilde{A}^* \rightarrow A^*_\text{Num} \). \( \square \)

Thus, \( A^*_\text{Num} \) plays the role opposite to that of \( A^*_0 \) and can be denoted as \( A^*_\infty \), and any generically constant theory \( \widetilde{A}^* \) with the formal group law \( \varphi \) is canonically squeezed between \( A^*_0 \) and \( A^*_\infty \):

\[ A^*_0 \rightarrow \widetilde{A}^* \rightarrow A^*_\infty, \]

and the latter provides an alternative way of describing such theories \( \widetilde{A}^* \).
4.2. Numerical equivalence modulo $p$ and isotropy

Everywhere below $X$ is a smooth projective variety over a field $k$ of characteristic zero.

In the case of a theory $\text{Ch}^* = \text{CH}^*/p$, we will denote the numerical equivalence \( \sim_{\text{Num}} \) to stress that we consider finite coefficients. Thus, $\text{Ch}_{\text{Num}}^N(X) = \text{Ch}^*(X)/N$, where $N$ is the ideal of elements $\sim_{\text{Num}} 0$. In our situation, $x \in \text{Ch}(X)$ is $\sim_{\text{Num}} 0$ if, for any $y \in \text{Ch}(X)$, the $\deg(x \cdot y) = 0 \in \mathbb{F}_p$.

By the very definition, we have a nondegenerate pairing

$$\text{Ch}_{\text{Num}}(X) \times \text{Ch}_{\text{Num}}(X) \rightarrow \mathbb{F}_p$$

defined by $(x, y) \mapsto \deg(x \cdot y)$. Moreover, because $\deg(x \cdot y)$ may be defined on the level of the (complex) topological realisation, the kernel of the topological realisation functor is contained in $N$, so $\text{Ch}_{\text{Num}}(X)$ is a subquotient of the topological cohomology $H_{\text{Top}}(X; \mathbb{F}_p)$ of $X$. In particular, $\text{Ch}_{\text{Num}}(X)$ is finite-dimensional $\mathbb{F}_p$-vector space. Note, however, that this subquotient depends on the ground field $k$, because for different fields the images of the topological realisation functor will be different.

The theory $\text{Ch}^*_{\text{Num}}$ inherits the action of the reduced power operations from $\text{Ch}^*$, as follows from Proposition 4.6 below. Recall that we have reduced power operations $P^i : \text{Ch}^* \rightarrow \text{Ch}^{*+i(p-1)}$ (see [2] and [21]) commuting with pull-back morphisms and the respective homological operations $P_i : \text{Ch}_* \rightarrow \text{Ch}_{*-i(p-1)}$ commuting with push-forwards. These are connected as follows:

$$P^i = \sum_{l=0}^i d_l(T_X) \cdot P_{i-l},$$

where $d_l$ satisfies Cartan’s formula and, for a line bundle $L$, $d_1(L) = x^p$, where $x = c_1(L)$.

**Proposition 4.6.** Let $u \in \text{Ch}^*(X)$. Then $u \sim_{\text{Num}(p)} 0 \Rightarrow P^i(u) \sim_{\text{Num}(p)} 0$.

**Proof.** Induction on $i$. Because $P^0 = \text{id}$, we have the (base) $i = 0$.

(step) We need to show that $\deg(P^i(u) \cdot v) = 0$, for any class $v$ of complementary dimension. By Cartan’s formula, $P^i(u) \cdot v = P^i(u \cdot v) - \sum_{j=0}^{i-1} P^j(u) \cdot P^{i-j}(v)$. By the inductive assumption, we have that $\deg(P^j(u) \cdot P^{i-j}(v)) = 0$, for any $j < i$. And the degree of the first summand can be rewritten as

$$\deg(P^i(u \cdot v)) = \deg \left( \sum_{l=0}^i d_l(T_X) \cdot P_{i-l}(u \cdot v) \right)$$

$$= \deg(P_i(u \cdot v)) + \deg \left( \sum_{l=1}^i d_l(T_X) \cdot \sum_{m=0}^{i-l} d_m(-T_X) \cdot P^{i-l-m}(u \cdot v) \right).$$

The second summand is zero by the inductive assumption, and the degree of $P_i(u \cdot v)$ is the same as that of $P_i(\pi_*(u \cdot v))$, where $\pi : X \rightarrow \text{Spec}(k)$ is the natural projection. The latter degree is equal to zero for any $i > 0$. The induction step is proven. \(\square\)
If $x$ is an anisotropic cycle, then $x^{\text{Num}(p)} = 0$. Indeed, $x = f_*(x')$ for some projective map $f : Z \to X$ from anisotropic variety $Z$ and some $x' \in \text{Ch}^*(Z)$. But then $\deg(x \cdot y) = \deg(f_*(x') \cdot y) = \deg(x' \cdot f^*(y)) = 0$, because all zero-cycles on $Z$ have zero degree (modulo $p$). Thus, we get the surjective map:

$$\text{Ch}_{k/k}^*(X) \twoheadrightarrow \text{Ch}_{\text{Num}}^*(X).$$

I conjecture that, over flexible fields, in reality these two cohomology theories coincide.

**Conjecture 4.7.** Let $k$ be a flexible field. Then $\text{Ch}_{k/k}^* = \text{Ch}_{\text{Num}}^*$.

**Remark 4.8.** The condition on the flexibility of $k$ is essential here. For example, if $k$ is algebraically closed, then from Remark 2.12 we know that $\text{Ch}_{k/k}^* = \text{Ch}^*$, and $\text{Ch}_{\text{Num}}^*$ is some subquotient of it. △

**Remark 4.9.** This conjecture, in particular, implies that the local Chow motivic category $\text{Chow}(k/k; \mathbb{F}_p)$ is equivalent to the numerical Chow motivic category $\text{Chow}_{\text{Num}}(k; \mathbb{F}_p)$.

Because the degree pairing is defined over the algebraic closure and even in the topological realisation, we obtain that the numerical Chow groups over $E$ are subquotients of the respective groups over $\overline{E}$, which, in turn, are subquotients of topological cohomology

$$\text{Ch}_{\text{Num}/E}(X) \hookrightarrow \text{Ch}_{\text{Num}/\overline{E}}(X) \hookrightarrow H_{\text{Top}}(X; \mathbb{F}_p).$$

Thus, our conjecture implies that any object of $\text{Chow}(k; \mathbb{F}_p)$ that vanishes over $\overline{k}$, or even in the topological realisation, should vanish in every isotropic category $\text{Chow}(E/E; \mathbb{F}_p)$.

In contrast, ‘non-pure’ motives behave differently. For example, the idempotent, corresponding to the projector $\pi_E : \text{DM}(k; \mathbb{F}_p) \to \text{DM}(E/k; \mathbb{F}_p)$, is mapped via $\psi_E$ to the unit object of the category $\text{DM}(E/E; \mathbb{F}_p)$. On the other hand, its restriction to $\overline{k}$ is trivial, because $\overline{\mathbb{Q}}|\overline{E} = 0$, for any nonempty $Q$ (note that $E \neq \overline{E}$, because $k$ is flexible, so the respective directed system contains nonempty $Q$s). Consequently, all of the subcategories $\text{DM}(E/k; \mathbb{F}_p)$, for all finitely generated $E/k$, are killed by the restriction to the algebraic closure functor $\text{DM}(k; \mathbb{F}_p) \to \text{DM}(\overline{k}; \mathbb{F}_p)$. There are geometric examples as well: the motive $\tilde{M}_a$ of Section 3 vanishes over $\overline{k}$ but is nonzero in the isotropic motivic category. △

**Remark 4.10.** Although the numerical Chow motivic category $\text{Chow}_{\text{Num}}(k; \mathbb{F}_p)$ is a subquotient of a topological category (that is, of the category of graded $\mathbb{F}_p$-vector spaces), it is more interesting. In particular, it is not generated by a single object (Tate motive). This is reflected by the absence of the Kunneth formula. Namely, for smooth projective $X$ and $Y$, the product map

$$\text{Ch}_{\text{Num}}(X) \otimes \text{Ch}_{\text{Num}}(Y) \to \text{Ch}_{\text{Num}}(X \times Y)$$

is not an isomorphism ($\nRightarrow$ not surjective), in general. △

Our aim is to prove the following result.

**Theorem 4.11.** Conjecture 4.7 is true in the following cases:

1. $\dim(X) \leq 5$;
(2) \( \text{Ch}^1 \);
(3) \( \text{Ch}_m \), for \( m \leq 2 \).

Item (2) will be proven in Proposition 4.15, item (3) follows from Corollary 4.16 and Propositions 4.20 and 4.23, and for item (1) we need to add Proposition 4.24.

**Corollary 4.12.** In the situation of Theorem 4.11, the local Chow groups \( \text{Ch}^*_{k/k}(X) \) are finite-dimensional \( \mathbb{F}_p \)-vector spaces.

This contrasts with the global situation, where Chow groups of varieties are often huge.

We have the following Chow-motivic questions of increasing strength related to Question 2.10.

**Question 4.13.**

1. Is it true that any \( U \in \text{Ob}(\text{Chow}(k; \mathbb{F}_p)) \) that vanishes in the (complex) topological realisation is zero?
2. Is it true that any \( f \in \text{End}_{\text{Chow}(k; \mathbb{F}_p)}(V) \) that vanishes in the (complex) topological realisation is nilpotent?

As we saw, by Conjecture 4.7, for a flexible field the triviality of the topological realisation should imply the triviality of all local realisations.

**Remark 4.14.** Note that the stronger variant of Question 4.13(2) fails. Namely, C. Soule and C. Voisin produced an example of a class \( c \in \text{Ch}^3(X) \), for some smooth projective \( X \), such that \( c \) vanishes in \( H^3_{\text{Top}}(X; \mathbb{F}_p) \), but \( c \) is not smash-nilpotent (that is, \( c \times r \neq 0 \in \text{Ch}^{3r}(X \times r) \), for any \( r \)) [13, Theorem 5].

If we are interested instead only in the triviality of local realisations, it is sufficient to take the image \( \overline{x} \) of any torsion class \( x \) from \( \text{CH}^1(X) \), whose topological realisation in \( H^2_{\text{Top}}(X; \mathbb{F}_p) \) is nontrivial. Then, because the degree pairing is defined integrally, \( \overline{x}|_E \sim_{\text{Num}(p)} 0 \), for any \( E/k \). Thus, all local realisations of \( \overline{x} \) are trivial by Theorem 4.11(2). At the same time, its topological realisation is nontrivial and thus not smash-nilpotent.

Hence, \( \overline{x} \) is not smash-nilpotent either. \( \triangle \)

A weaker variant of Question 4.13 with ‘topological realisation’ replaced by the ‘restriction to the algebraic closure’ is a safer bet. In this form, question (2) becomes the **Rost Nilpotence Conjecture**.

### 4.3. The proof of the Main Theorem

**4.3.1. Divisors and zero-cycles.** We start the proof of Theorem 4.11 with the case of divisors (item (2)), which is actually the base for the whole technique.

**Proposition 4.15.** Let \( k \) be a flexible field and \( u \in \text{Ch}^1(X) \) be \( \sim_{\text{Num}(p)} 0 \). Then \( u = 0 \in \text{Ch}^1_{k/k}(X) \).

**Proof.** Adding to an effective divisor representing \( u \) a \( p \)-multiple of a very ample divisor, we may assume that \( u \) is represented by a very ample divisor \( D \). Let \( (\mathbb{P}^n)^\vee = \text{Proj}|D| \)
be the projective linear system of \(D\). This defines the embedding of \(X\) into \(\mathbb{P}^n\). From Statement 6.3, the embedding \(t : D_\eta \to X\) of the generic representative of our linear system into \(X\) induces a surjective map \(t^* : \text{Ch}_1(X) \to \text{Ch}_0(D_\eta)\). But because \(D \sim \text{Num}(\eta) 0\), the degree of the zero-cycle \(t^*(v)\) is zero for any \(v \in \text{Ch}_1(X)\). Hence, \(D_\eta\) is anisotropic. Thus, over \(k((\mathbb{P}^n)^*)\), our class \(u\) is represented by the class of an anisotropic divisor \(D_\eta\). Because \(k\) is flexible, it is represented by an anisotropic class already over \(k\) (by Proposition 1.3).

Because the theory \(\text{Ch}_{k/k}^*\) has the structure of push-forwards and pull-backs, we obtain the following.

**Corollary 4.16.** Let \(k\) be a flexible field. The projection \(\text{Ch}^* \to \text{Ch}_{k/k}^*\) passes through \(\text{Ch}_{alg}^* = \text{Ch}_{(1)}^*\).

**Proof.** A class \(u \in \text{Ch}^*(X)\) is algebraically equivalent to zero if it can be presented as \(f_* (y \cdot g^*(v))\), where \(X \xleftarrow{f} X \times C \xrightarrow{g} C\) are natural projections, \(C\) is a smooth projective curve, \(y \in \text{Ch}^*(X \times C)\) and \(v \in \text{Ch}_0(C)\) is a zero-cycle of degree zero. Because \(v \sim \text{Num}(\eta) 0\), Proposition 4.15 implies that \(v = 0 \in \text{Ch}_{k/k}^*(C)\), so \(u = 0 \in \text{Ch}_{k/k}^*(X)\).

Because any zero-cycle on a smooth projective variety \(X\) is a push-forward of some zero-cycle from a curve, we also get the case of zero-cycles.

**Corollary 4.17.** Let \(k\) be a flexible field and \(u \in \text{Ch}_0(X)\) be \(\sim \text{Num}(\eta) 0\). Then \(u = 0 \in \text{Ch}_{k/k;0}(X)\).

Our general strategy of proving that the class \(u \sim \text{Num}(\eta) 0\) is anisotropic will be to find an appropriate blow-up \(\pi : \tilde{X} \to X\), so that \(\pi^* u\) may be represented by a cycle supported on a smooth connected divisor \(Z \subset \tilde{X}\), which is \(\sim \text{Num}(\eta) 0\) already on \(Z\). Then we use induction on the dimension of \(X\) and the fact that \(u = \pi_* \pi^* u\). In order to achieve this, we will need first to present \(u\) by the class of a smooth connected subvariety \(S\) and make the appropriate characteristic classes of it \(\sim \text{Num}(\eta) 0\) on \(X\).

### 4.3.2. 3-folds and 1-cycles

We will be moving up the dimension of varieties. The above statements settle the case of curves and surfaces. Our next aim are 3-folds, where only the case of 1-cycles remains open.

**Proposition 4.18.** Let \(k\) be a flexible field and \(X\) be a smooth projective variety over \(k\) of dimension 3. Let \(u \in \text{Ch}_1(X)\) be \(\sim \text{Num}(\eta) 0\). Then \(u = 0 \in \text{Ch}_{k/k;1}(X)\).

**Proof.** We will show that there is a blow-up \(\pi : \tilde{X} \to X\) such that \(\pi^*(u)\) is represented by the class of a smooth anisotropic curve on \(\tilde{X}\). Because \(\pi_* \pi^*(u) = u\), this will show that the class \(u\) is anisotropic. Here, as in many statements below, we will be gradually reducing a general case to the one with better and better special properties.

**Lemma 4.18.1.** We may assume that \(u\) is represented by a class of a smooth curve \(S\) on \(X\) and, moreover, \(\deg(c_1(N_{S < X}) \cdot [S]) = 0 \ (\text{mod } p)\).
Proof. By Corollary 6.2, after some blow-up, we may represent \( u \) by the class of a smooth curve \( S \) on \( X \) (we keep the same name for the variety). Note that \( c_1(N_{S \subset X}) = c_1(T_X) + c_1(-T_S) \) and \( \deg(c_1(T_X) \cdot [S]) = 0 \), because \( [S]^{\Num(p)} \sim 0 \) and \( c_1(T_X) \) is a class defined on \( X \). Now we need to treat separately \( p = 2 \) and odd primes. Such separate treatment of different primes is the feature that we will see repeatedly below.

\( (p = 2) \) Our degree is equal to the \( \deg(c_1(-T_S) \cdot [S]) = \deg(P_1([S])) \), where \( P_1 \) is the homological Steenrod operation \( Sq^2 \). But \( \deg(P_1([S])) = \deg(P_1(\epsilon_*[S])) \), where \( \epsilon : S \to \Spec(k) \) is the projection, and \( \epsilon_*[S] = 0 \).

\( (p \neq 2) \) Let \( [Z] \) be a smooth very ample divisor on \( S \) representing \( \frac{1}{2}c_1(-T_S) \) in \( \text{Ch}_0(S) \). Let \( \pi : \widetilde{X} \to X \) be the blow-up of \( X \) at \( Z \). Let \( \tilde{S} \) be the proper pre-image of \( S \) in \( \tilde{X} \). Then by [5, Theorem 6.7], we have

\[
\pi^*([S]) = [\tilde{S}] + [\mathbb{P}^1_Z],
\]

where \([\mathbb{P}^1_Z]\) is the class supported on the special divisor \( \mathbb{P}^2_Z \). Therefore, \( \pi^*([S]) \) is represented by the class of a smooth curve \( S' = \tilde{S} \bigcup \mathbb{P}^1_Z \) (we can always choose the curve \( \mathbb{P}^1_Z \) not intersecting \( \tilde{S} \)). Note that \( \tilde{S} \cong S \). Then

\[
\deg(c_1(-T_{S'}) \cdot [S']) = \deg(c_1(-T_{\tilde{S}}) \cdot [\tilde{S}]) + \deg(c_1(-T_{\mathbb{P}^1_Z}) \cdot [\mathbb{P}^1_Z]) = \deg(c_1(-T_S) \cdot [S]) + \deg([Z]) \cdot (-2) = 0.
\]

Now, in addition, we can make our class to be supported on some smooth surface.

Lemma 4.18.2. We may assume that \( u \) is represented by the class of a smooth (possibly, disconnected) curve \( S \) that is contained in some smooth (possibly, disconnected) surface \( E \) on \( X \), and the curve \( S \) also satisfies \( \deg(c_1(N_{S \subset X}) \cdot [S]) = 0 \).

Proof. By Lemma 4.18.1, we can assume that \( u = [S] \), where \( S \subset X \) is a smooth curve and, moreover, \( \deg(c_1(N_{S \subset X}) \cdot [S]) = 0 \). Consider \( \tilde{X} = \text{Bl}_S(X) \) with the projection \( \pi : \tilde{X} \to X \). Then \( \pi^*(u) \) is supported on \( E = \mathbb{P}_S(N_{S \subset X}) \), which is a smooth surface. More precisely, it is represented by \( \rho + \epsilon^*c_1(N_{S \subset X}) \), where \( \epsilon : E \to S \) is the natural projection and \( \rho = c_1(O(1)) = -[E] \). By adding a \( p \)-multiple of a very ample divisor, we can assume (by Statement 6.4) that \( \pi^*(u) \) is represented by a very ample divisor on every component of \( E \) and so is represented by a smooth curve \( S' \) on \( E \). Moreover, \( c_1(N_{S' \subset \tilde{X}}) \) is the restriction of \( \epsilon^*c_1(N_{S \subset X}) \) to \( S' \). Hence, \( \deg(c_1(N_{S' \subset \tilde{X}}) \cdot [S']) = \deg(c_1(N_{S \subset X}) \cdot \epsilon_*([S'])) = \deg(c_1(N_{S \subset X}) \cdot [S]) = 0 \).

In view of Corollary 6.12, it remains to make our curve and surface connected.

Lemma 4.18.3. We may assume that \( u \) is represented by the class of a smooth connected curve contained in a smooth connected divisor \( E \) on \( X \), and the curve \( S \) also satisfies \( \deg(c_1(N_{S \subset X}) \cdot [S]) = 0 \).

Proof. By Lemma 4.18.2 we may assume that \( u = [S] \), where \( S \) is smooth and \( S \subset E' \subset X \), where \( E' \) is a (possibly disconnected) smooth surface and \( \deg(c_1(-T_S) \cdot [S]) = \deg(c_1(N_{S \subset X}) \cdot [S]) = 0 \). By Statement 6.5 applied to the divisor \( E' \) considered as a
Let \( u \) and Proposition 4.18, Proposition 4.20.

on a variety of an arbitrary dimension.

Ac l a s s

Proof. E is flexible, we may assume that the divisor \( E \) divisor single component, over some purely transcendental extension of \( k \), there is an irreducible divisor \( E'' \) on \( X \) containing \( S \) and smooth outside an anisotropic subset. Because \( k \) is flexible, we may assume that the divisor \( E'' \) of \( X \) is defined already over \( k \). Let \( \pi : \tilde{X} \to X \) be the embedded desingularization of \( E'' \). Let \( \tilde{E} \) be the proper pre-image of \( E'' \) and \( \tilde{S} \) be the proper pre-image of \( S \). Then \( \pi^*(u) \) is equal to \([\tilde{S}]\) plus some classes supported on the special divisors of our blow-up. But these special divisors are anisotropic (because the singularities were). Hence, modulo anisotropic classes, \( \pi^*(u) \) is equal to the class \([\tilde{S}]\) supported on a smooth connected surface \( \tilde{E} \). And because \( \tilde{S} \cong S \), we have \( \deg(c_1(-T_{\tilde{S}}) \cdot [\tilde{S}]) = \deg(c_1(-T_S) \cdot [S]) = 0 \). Our class is a divisor on \( \tilde{E} \). Adding a \( p \)-multiple of an appropriate very ample divisor, we may assume that our divisor is very ample (by Statement 6.4) and thus is represented by a smooth connected curve on \( \tilde{E} \). Note that this procedure does not change the \( \deg(c_1(-T_S) \cdot [S]) = 0 \in \mathbb{F}_p \).

Proposition 4.18 follows now from Corollary 6.12 and flexibility of \( k \).

Now, the case of varieties of dimension \( \leq 3 \) is settled, which, due to the presence of push-forwards and pull-backs, implies that isotropic Chow groups factor through the second theory of higher type.

**Proposition 4.19.** Let \( k \) be a flexible field. The projection \( \text{Ch}^* \to \text{Ch}^*_{k/k} \) factors through \( \text{Ch}^*_{(2)} \).

**Proof.** A class \( u \in \text{Ch}^*(X) \) is \( = 0 \in \text{Ch}^*_{(2)} \), if it can be presented as \( f_*(y \cdot g^*(v)) \), where \( X \xleftarrow{f} X \times Q \xrightarrow{g} Q \) are natural projections, \( Q \) is a smooth projective variety of dimension 3, \( y \in \text{Ch}^*(X \times Q) \) and \( v \in \text{Ch}^*(Q) \) is \( \sim \) 0. Then, by Proposition 4.15, Corollary 4.17 and Proposition 4.18, \( v = 0 \in \text{Ch}^*_{k/k}(Q) \), so \( u = 0 \in \text{Ch}^*_{k/k}(X) \).

The case of surfaces and 3-folds permits starting induction and dealing with 1-cycles on a variety of an arbitrary dimension.

**Proposition 4.20.** Let \( k \) be a flexible field and \( X \) be a smooth projective variety over \( k \). Let \( u \in \text{Ch}^1(X) \) be \( \sim \) 0. Then \( u = 0 \in \text{Ch}^*_{k/k;1}(X) \).

**Proof.** Induction on \( n = \dim(X) \).

(base) The case \( n = 1 \) is trivial. The cases \( n = 2 \) and \( n = 3 \) follow from Propositions 4.15 and 4.18, respectively.

(step \((n-1) \to (n)\)) We may assume that \( n > 3 \).

First of all, we need to make our class supported on a smooth divisor.

**Lemma 4.20.1.** We may assume that \( u \) is represented by a class supported on some smooth (possibly disconnected) divisor \( Z \) on \( X \).

**Proof.** By Corollary 6.2, we may assume that \( u \) is represented by the class of a smooth curve \( S \) on \( X \). Consider the blow-up \( \pi : \tilde{X} = \text{Bl}_S(X) \to X \). Then \( \pi^*(u) \) is supported on the special divisor \( E = \mathbb{P}_S(N_{S \subset X}) \), which is smooth.
Now we can make the supporting (smooth) divisor connected and, in addition, we can make all codimension 1 classes on it restrictions of some classes from \( X \), at least, modulo anisotropic classes.

**Lemma 4.20.2.** We may assume that \( u \) is represented by a class supported on some smooth connected divisor \( Z \) on \( X \) such that the restriction \( \text{Ch}^1_{k/k}(X) \to \text{Ch}^1_{k/k}(Z) \) is surjective.

**Proof.** By Lemma 4.20.1, we may assume that \( u \) is represented by the class of a curve \( S \) contained in a smooth divisor \( Z \). By Statement 6.5 and flexibility of \( k \), \( S \) is contained in some irreducible divisor \( Z' \), smooth outside an anisotropic subset, and such that the restriction \( \text{Ch}^1_{k/k}(X) \to \text{Ch}^1_{k/k}(Z'\setminus S) \) is surjective. Because \( \dim(Z') - 1 > 1 = \dim(S) \), we also get the surjection \( \text{Ch}^1_{k/k}(X) \to \text{Ch}^1_{k/k}(Z') \).

Let \( \pi : \tilde{X} \to X \) be the embedded resolution of singularities of \( Z' \). Because the singularities of \( Z' \) were anisotropic, the special divisors of \( \tilde{X} \) will be also such. Let \( \tilde{Z}' \) be the proper pre-image of \( Z' \) and \( \tilde{S} \) be the proper pre-image of \( S \). Then \( \text{Ch}^*_{k/k}(Z') = \text{Ch}^*_{k/k}(\tilde{Z}') \), so the map \( j^* : \text{Ch}^1_{k/k}(X) \to \text{Ch}^1_{k/k}(\tilde{Z}') \), induced by the natural projection \( f : \tilde{Z}' \to X \), is surjective. The image of \( \pi^*(u) \) in \( \text{Ch}^*_{k/k}(\tilde{X}) = \text{Ch}^*_{k/k}(X) \) is represented by the class of \( \tilde{S} \) supported on \( \tilde{Z}' \).

Because the restriction \( j^* : \text{Ch}^1_{k/k}(X) \to \text{Ch}^1_{k/k}(Z) \) is surjective, \( u = j_*(u') \), for some class \( u' \in \text{Ch}^1_{k/k;1}(Z) \), and \( u \equiv 0 \) on \( X \), we get that \( u' \equiv 0 \) on \( Z \). Because \( Z \) is a smooth connected projective variety of dimension \( n - 1 \), by the inductive assumption, \( u' = 0 \in \text{Ch}^1_{k/k;1}(Z) \). Then the class \( u \) is equal to \( 0 \in \text{Ch}^1_{k/k;1}(X) \) as well. Proposition 4.20 is proven.

4.3.3. 4-folds. The next target is 4-folds, where only the case of codimension 2-cycles is left.

**Proposition 4.21.** Let \( k \) be a flexible field and \( X \) be a smooth projective \( k \)-variety of dimension 4. If \( u \in \text{Ch}^2_k(X) \) is \( \equiv 0 \) on \( \text{Num}(p) \), then \( u = 0 \in \text{Ch}^2_{k/k}(X) \).

**Proof.** Our strategy will be to find an appropriate blow-up \( \pi : \tilde{X} \to X \) such that \( \pi^*(u) \) is supported on some smooth connected divisor \( Z \) and is \( \equiv 0 \) on it.

By Corollary 6.2, we may assume that \( u \) is represented by the class of a union of smooth complete intersections of very ample divisors with components meeting transversally. In such a situation (of transversal smooth components), let us denote as \( c^2_1(N_{S\subset X}) \cdot [S] \) the sum \( \sum_i c^2_1(N_{S_i\subset X}) \cdot [S_i] \), and similar for other characteristic classes.

The case of a prime 2 requires certain preparations to be made still at this level of transversal complete intersections, before passing to a single smooth subvariety (to be done in the next step).

**Lemma 4.21.1.** We may assume that \( u \) is represented by the class of \( \bigcup_i S_i \), where each \( S_i \) is a complete intersection of very ample divisors, with components meeting transversally. For \( p = 2 \), we may moreover assume that \( \deg(c^2_1(N_{S\subset X}) \cdot [S]) = 0 \).
Proof. Let \( p = 2 \) and \( |S| = \sum_i x_i y_i \), where \( x_i \) and \( y_i \) are classes of very ample divisors. Then, in \( \text{Ch}^2 \), we can substitute this presentation by

\[
[S’] = \sum_i (x_i y_i + x_i (x_i + y_i) + (x_i + y_i)(x_i + y_i)),
\]

where all of the divisor classes involved are very ample and thus components can be made transversal. Then \( c_i^2(N_{S’} \subset X) \cdot [S’] = \sum_i (x_i y_i + x_i y_i)^2 + x_i (x_i + y_i) y_i^2 + y_i (x_i + y_i) x_i^2 + 0) = 0. \)

For a surface \( S = \bigcup_i S_i \) with smooth transversal components, let us denote \( \Lambda^2[S] := \sum_{\{i,j\}} [S_i] \cdot [S_j] \) in \( \text{Ch}_0(X) \), where the sum is over all 2-element subsets of the set of components.

The following result permits combining our transversal components into a single smooth connected surface. Moreover, there is some control over the characteristic classes of the surface obtained this way.

Lemma 4.21.2. Let \( S = \bigcup_i S_i \) be a surface on \( X \) with smooth transversal components. Then there exists a blow-up \( \eta : \hat{X} \to X \) such that \( \eta^*(|S|) \) is represented by the class of a smooth connected surface \( \hat{S} \) contained in a smooth connected divisor \( \hat{D} \), and

\[
\deg(c_i^2(N_{\hat{S} \subset \hat{X}}) \cdot [\hat{S}]) = \deg(c_i^2(N_{S \subset X}) \cdot |S| - 2 \Lambda^2(|S|)).
\]

If, moreover, \( |S| \stackrel{\text{Num}(p)}{\sim} 0 \), then this degree is equal to the deg \((c_1^2 + c_2)(N_{S \subset X}) \cdot |S|)\).

Proof. Let \( u = \bigcup_i S_i = \sum_i u_i \) be the class of \( |S| \). Let \( \pi : \tilde{X} \to X \) be the blow-up of \( X \) in all components \( S_i \). Let \( E_i \) be the respective components of the special divisor and \( \rho_i = c_1(O(1)) = [-E_i] \). Then, by [16, Proposition 5.27], \( \tilde{S}_i = \pi^*(|S_i|) = [E_i] \cdot (c_1(N_{S_i} \subset X) + \rho_i) \) is supported on \( E_i \) and may be represented by a smooth surface \( \tilde{S}_i \). Note that \( c_1(N_{\tilde{S}_i} \subset \tilde{X}) = \pi^*(c_1(N_{S_i} \subset X)) \), so \( \deg(c_i^2(N_{\tilde{S}_i} \subset \tilde{X}) \cdot [\tilde{S}]) = \deg(c_i^2(N_{S_i} \subset X) \cdot |S|) \).

Let \( T_{i,j} = E_i \cap E_j \) be the intersection of the components of the special divisor, and \( t_{i,j} = [T_{i,j}] \). We have \( \deg(\tilde{u}_i \cdot \tilde{u}_j) = \deg(u_i \cdot u_j) \), and \( \deg(\tilde{u}_i \cdot t_{i,j}) = \deg([-E_i] \cdot [E_j]) = 0 \) and \( \deg(\tilde{u}_i \cdot t_{j,k}) = 0 \), for any \( i \not\in \{j,k\} \), as well. Finally, \( \deg(t_{i,j}^2) = \deg([-E_j] \cdot \rho_i \cdot \rho_j) = \deg(u_i \cdot u_j) \), and \( t_{i,j} \cdot t_{k,l} = 0 \), for \( i,j \not\in \{k,l\} \). Now, for all pairs \( (i,j) \) of distinct numbers let us choose signs \( \epsilon_{(i,j)} \in \pm 1 \) with the condition that \( \epsilon_{(i,j)} + \epsilon_{(j,i)} = 0 \). Let us substitute classes \( \tilde{u}_i \) by \( \tilde{u}_i := \tilde{u}_i + \sum_{j \neq i} \epsilon_{(i,j)} t_{i,j} \). Note that the sum \( \sum_i \tilde{u}_i \) is still equal to the \( \sum_i u_i = \pi^*(u) \). On the other hand,

\[
\deg(\tilde{u}_i \cdot \tilde{u}_j) = \deg\left(\left(\tilde{u}_i + \sum_{k \neq i} \epsilon_{(i,k)} t_{i,k}\right) \cdot \left(\tilde{u}_j + \sum_{l \neq j} \epsilon_{(j,l)} t_{j,l}\right)\right) = \deg(u_i \cdot u_j) - \deg(t_{i,j} \cdot t_{j,i}) = 0.
\]

Because these classes \( \tilde{u}_i \) are divisors on (connected) \( E_i \), we can make them very ample (by adding a \( p \)-multiple of some very ample divisor), so we can move them around and make them smooth connected and transversal to any given subvariety. Let \( \tilde{S}_i \) be the generic representative of the respective linear system \( |\tilde{u}_i| \) on \( E_i \). It is a smooth connected surface on \( E_i \) representing \( \tilde{u}_i \). We now have a divisor with strict normal crossings \( E_i = \bigcup_i E_i \) and a surface \( \tilde{S}’ = \bigcup_i \tilde{S}_i \) on it, with \( \tilde{S}_i \) smooth connected, transversal to each other and to the other components of \( E \).
Let us assume that \( S_i \cap \tilde{S}_j \) are anisotropic. Because \( k \) is flexible, we may assume that \( \tilde{S}_i \) is defined already over \( k \) (by Proposition 1.3). Finally, denoting \( \gamma_i = \pi^*(c_1(N_{S_i \subset X})) \), because \( \rho_i \rho_j \gamma_i, \rho_i \rho_i \rho_k \) are zero, for distinct \( i, j, k \), we have

\[
\deg(c_1^2(N_{S_1 \subset \tilde{X}}) \cdot [\tilde{S}]) = \sum_d \left( \deg(-\rho_i(\gamma_i + \rho_i + \sum_{j \neq i} \epsilon_{(i,j)} \rho_i) + \sum_{j \neq i} \epsilon_{(i,j)} \rho_j)^2 \right) \\
\sum_i \deg(-\rho_i(\gamma_i + \rho_i + \sum_{j \neq i} \epsilon_{(i,j)} \rho_i)) = \deg(c_1^2(N_{S_1 \subset \tilde{X}}) \cdot [\tilde{S}) - 2\Lambda^2([S]) \\
= \deg(c_1^2(N_{S_1 \subset X}) \cdot [S] - 2\Lambda^2([S])).
\]

If \( [S] \sim 0 \), then \( \deg(2\Lambda^2([S])) = \deg([S] \cdot [S] - \sum_i [S_i] \cdot [S_i]) = -\deg(c_2(N_{S_1 \subset X}) \cdot [S]). \) Thus, in this case, \( \deg(c_1^2(N_{S_1 \subset X}) \cdot [S] - 2\Lambda^2([S])) = \deg((c_1^2 + c_2)(N_{S_1 \subset X}) \cdot [S]). \)

After all, we managed to present our cycle by the class of the union of smooth surfaces transversal to each other and all intersections anisotropic. It remains to use Statement 6.6.

In order to apply Corollary 6.12, we need to eliminate (numerically) the powers of the first Chern class of the normal bundle of our surface. We will proceed from highest to smallest powers.

**Lemma 4.21.3.** We may assume that \( u \) is represented by the class of a smooth connected surface \( S \) that is contained in a smooth connected divisor \( Z \), and \( \deg(c_1^2(N_{S \subset X}) \cdot [S]) = 0 \in \mathbb{F}_p. \)

**Proof.** By Lemmas 4.21.1 and 4.21.2, we may assume that \( u \) is represented by the class of a smooth connected surface \( S \) contained in a smooth connected divisor \( Z \), and (again by the same lemmas) we already know the case \( (p = 2) \). We need to treat separately \( p = 3 \) and the remaining primes.

**\( (p = 3) \)** Let \( d_1 = c_1^2 + c_2 \). This characteristic class of degree 2 corresponds to the reduced power operation \( P^1 : \text{Ch}^g \to \text{Ch}^{g+2} \). Namely, \( P^1([S]) = d_1(N_{S \subset X}) \cdot [S] \). By Proposition 4.6, \( \deg(d_1(N_{S \subset X}) \cdot [S]) = 0 \in \mathbb{F}_3 \), because \( [S] \sim 0 \). On the other hand, \( \deg(c_2(N_{S \subset X}) \cdot [S]) = \deg([S] \cdot [S]) = 0 \) (by the same reason). Hence, \( \deg(c_1^2(N_{S \subset X}) \cdot [S]) = 0 \in \mathbb{F}_3. \)

**\( (p \neq 2, 3) \)** Let \( R \) be a smooth zero-cycle representing the complete intersection (of very ample divisors) \( \frac{1}{2}c_1(N_{S \subset X}) \cdot \frac{1}{3}c_1(N_{S \subset X}) \) on \( S \). Let \( \pi : \tilde{X} = \text{Bl}_R(X) \to X \) be the blow-up of \( X \) at \( R \), and \( E = \pi \) be the special divisor of \( \pi \), with \( \rho = c_1(O(1)) = -[E] \). Then \( \pi^*([S]) = [\tilde{S}] + [F] \), where \( \tilde{S} \) is the proper transform of \( S \), and \( [F] = [E] \cdot (\epsilon^*(c_1(N_{S \subset X}) + \rho) \). We have \( c_1(N_{\tilde{S} \subset \tilde{X}}) = 2\rho + \pi_S^*(c_1(N_{S \subset X})) \), and \( c_1(N_{S \subset \tilde{X}}) = \epsilon^*(c_1(N_{S \subset X})) \). Hence (taking into account that \( \pi(E) \) is zero-dimensional),

\[
c_1^2(N_{\tilde{S} \subset \tilde{X}}) \cdot [\tilde{S}] + c_1^2(N_{F \subset \tilde{X}}) \cdot [F] = j_* \pi_S^*(c_1^2(N_{S \subset X}) \cdot [S]) + 4\rho^2 \cdot [\tilde{S}] \\
= j_* \pi_S^*(c_1^2(N_{S \subset X}) \cdot [S] - 4[R]) = j_* \pi_S^* \left( \frac{1}{3} c_1^2(N_{S \subset X}) \cdot [S] \right).
\]
The characteristic class $Z$ is represented by the class of a smooth connected surface $S$ contained in a smooth connected divisor $Z$ with
\[ \deg(c_1^2(N_{S_{\mathbb{C}} X}) \cdot [S]) = \deg(c_1^2(N_{S_{\mathbb{C}} X}) \cdot [S]) + \deg(c_1^2(N_{F_{\mathbb{C}} X}) \cdot [F]) - \deg(2[S] \cdot [F]) = \deg\left(\frac{1}{2} c_1^2(N_{S_{\mathbb{C}} X}) - \frac{1}{2} c_1^2(N_{S_{\mathbb{C}} X}) \cdot [S]\right) = 0. \]

It remains to treat the first power of the first Chern class.

Lemma 4.21.4. We may assume that $u$ is represented by the class of a smooth connected surface $S$ that is contained in a smooth connected divisor $Z$, with $c_1^2(N_{S_{\mathbb{C}} X}) \cdot [S] \sim 0$ and $c_1(N_{S_{\mathbb{C}} X}) \cdot [S] \sim 0$.

Proof. By Lemma 4.21.3, we may assume that $u = [S]$, where $S \subset Z \subset X$ are smooth connected, with the needed condition on $c_1^2$. It remains to terminate $c_1$. We need to treat separately $p = 2$ and larger primes.

(\( p = 2 \)) The characteristic class $c_1$ corresponds to the reduced power operation $P^1 : \text{Ch}^r \to \text{Ch}^{r+1}$ (modulo 2). Because $[S] \sim 0$, by Proposition 4.6, $c_1(N_{S_{\mathbb{C}} X}) \cdot [S] = P^1([S]) \sim 0$.

(\( p \neq 2 \)) Let $R$ be a smooth connected curve on $S$ representing $\frac{1}{2} c_1(N_{S_{\mathbb{C}} X}) \cdot [S]$. Let $\pi : \tilde{S} = \text{Bl}_R(X) \to X$ be the blow-up at $R$, with the (connected) special divisor $E \to S$ and $\rho = c_1(O(1)) = -[E]$. Then $\pi^*([S]) = [\tilde{S}] + [F]$, where $\tilde{S}$ is the proper pre-image of $S$, and $[F] = [E] \cdot (\pi^*(c_1(N_{S_{\mathbb{C}} X}) + \rho))$ is supported on $E$. Note that $\pi_S : \tilde{S} \to S$ is an isomorphism. Then
\[ c_1^m(N_{S_{\mathbb{C}} X}) \cdot [\tilde{S}] = [\tilde{S}] \cdot (\pi_S^*(c_1(N_{S_{\mathbb{C}} X}) + 2 \rho)^m = 0 \in \text{Ch}^*(\tilde{X}) \text{, for } m > 0, \]
because $\rho + \pi_S^*(\frac{1}{2} c_1(N_{S_{\mathbb{C}} X})) = 0$ on $\tilde{S}$.

Because $c_1^2(N_{S_{\mathbb{C}} X}) \cdot [S] \sim 0$ on $X$, and $R$ is connected, we have that $c_1(N_{S_{\mathbb{C}} X}) \cdot R \sim 0$ on $R$, which implies that $[E] \cdot \pi^*(c_1(N_{S_{\mathbb{C}} X})) \sim 0$ on $E$. Hence,
\[ c_1^m(N_{F_{\mathbb{C}} X}) \cdot [F] = [E] \cdot (\pi^*(c_1(N_{S_{\mathbb{C}} X}) + 2 \rho) \cdot \pi^*(c_1^m(N_{S_{\mathbb{C}} X})) \sim 0 \text{ on } \tilde{X}, \text{ for } m > 0. \]

Finally, $[\tilde{S}] \cdot [F] = [\tilde{S}] \cdot (-\rho) \cdot (\pi_S^*(c_1(N_{S_{\mathbb{C}} X}) + \rho) = [\tilde{S}] \cdot \pi_S^*(\frac{1}{2} c_1(N_{S_{\mathbb{C}} X})) \cdot \pi_S^*(\frac{1}{2} c_1(N_{S_{\mathbb{C}} X})) \sim 0 \text{ on } \tilde{S}, \text{ because } c_1^2(N_{S_{\mathbb{C}} X}) \cdot [S] \sim 0 \text{ on } S$.

Substituting $F$ by the generic representative of the (very ample) linear system $|F|$ on $E$, by the proof of Proposition 4.15 we may assume that the intersection $\tilde{S} \cap F$ is anisotropic. Then, by Statement 6.6, there exists a blow-up $\mu : X' \to X$ such that $\mu^* \pi^*(|S|)$ is represented by the class of a smooth connected surface $\tilde{S}$ contained in a smooth connected divisor $\tilde{Z}$, such that $c_1^m(N_{S_{\mathbb{C}} X}) \cdot [\tilde{S}] \sim \mu^* c_1^m(N_{\tilde{S}_{\mathbb{C}} X}) \cdot [\tilde{S}] + c_1^m(N_{F_{\mathbb{C}} X}) \cdot [F] \sim 0$, for $m \geq 0$. \( \square \)
The characteristic class
If the degrees of Chern class numerically trivial already on the surface itself (not just after the push-forward 4-folds) will form a base of our induction.

4.3.4. 2-cycles. The case of 4-folds is completed. Our next destination is 2-cycles. The main difficulty here is the case of 2-cycles on a 5-fold, which (together with the treated 4-folds) will form a base of our induction.

Proposition 4.22. Let $k$ be a flexible field and $X$ be a smooth projective $k$-variety of dimension 5. If $u \in \text{Ch}_2(X)$ is $\text{Num}(p) \sim 0$, then $u = 0 \in \text{Ch}_{k/k;2}(X)$.

Proof. The strategy, as usual, is to find an appropriate blow-up, so that the pull-back of $u$ is supported on some smooth connected divisor $Z$ and is $\text{Num}(p) \sim 0$ already on $Z$.

We start by presenting $u$ by the class of a disjoint union of smooth complete intersections and eliminating numerically its second (normal) Chern class.

Lemma 4.22.1. We may assume that $u$ is represented by the class of a smooth surface $S$ on $X$, with all components complete intersections and $\deg(c_2(N_{S\subset X}) \cdot [S]) = 0 \in \mathbb{F}_p$.

Proof. By Corollary 6.2, we may assume that $u$ is represented by the class of a disjoint union of smooth complete intersections: $u = [S] = \bigsqcup_{i} S_i$. We need to treat separately the case $p = 2$ and that of odd primes.

$p = 2$ The characteristic class $c_2$ corresponds to the reduced power operation $P^2$ (modulo 2); that is, $P^2([S]) = c_2(N_{S\subset X}) \cdot [S]$. But $[S] \sim 0$, so by Proposition 4.6, $P^2([S]) \sim 0$, too. Hence, $\deg(c_2(N_{S\subset X}) \cdot [S]) = 0 \in \mathbb{F}_2$.

$p \neq 2$ If the degrees of $c_2$ of all of the components are trivial, there is nothing to prove. Otherwise, there is a component $S_l$ given by $x_1 x_2 x_3$ such that $\deg(x_1^2 x_2^2 x_3) = r \neq 0 \in \mathbb{F}_p$.

Let $R$ be a disjoint union of $d$ copies of the curve $x_1^2 x_2^2$, where one factor of $x_1$ and $x_2$ here is the same as in $S_l$ and the other one is generic, so that $Q = R \cap S_l$ is given by the $d$ disjoint copies of $x_1^2 x_2^2 x_3$ and $R$ does not meet other components of $S$. Let $\pi : \tilde{X} \to X$ be the blow-up at $R$ with the special divisor $E$ and $\rho = c_1(O(1)) = -[E]$.

Then, by [5, Theorem 6.7], $\pi^*(S_l) = [\tilde{S}_l] + [V]$, where $\tilde{S}_l \to S_l$ is the proper transform of $S_l$ and $V = \mathbb{P}^2_Q$ is a subvariety of the $Q$-fibre of the $\mathbb{P}^3$-bundle $E \to R$. Here $\tilde{S}_l$ is a complete intersection $(x_1 + \rho)(x_2 + \rho)x_3$, and $V$ is a complete intersection $-\rho^2 \cdot x_3$. We can move $[Q]$ along $R$ and make $V$ disjoint from $\tilde{S}_l$ (it is automatically disjoint from other components). On $\tilde{S}_l$, $x_i \cdot \rho = 0$ (because $\pi_S(\tilde{S} \cap E)$ is zero-dimensional) and $\rho^2 = -\pi_S^*[Q]$, and on $V = \mathbb{P}^2_Q$, $x_i = 0$ and $\rho^2$ is the class of a section $Q \to \mathbb{P}^2_Q$. Hence,

$$\deg(c_2(N_{\tilde{S}_l \subset \tilde{X}}) \cdot [\tilde{S}_l]) + \deg(c_2(N_{V \subset \tilde{X}}) \cdot [V]) = \deg((x_1 x_2 + x_2 x_3 + x_3 x_1 + \rho^2)[\tilde{S}_l])$$

$$+ \deg(-\rho^2[V]) = \deg(c_2(N_{S\subset X})[S]) - 2\deg([Q]) = \deg(c_2(N_{S\subset X})[S]) - 2rd.$$ 

Because $p \neq 2$, by choosing $d$ appropriately, we can always make the total degree of $c_2(N_{S\subset X}) \cdot [S]$ zero (in $\mathbb{F}_p$), while keeping all of the components complete intersections.

Having made the second (normal) Chern class of our surface numerically trivial, now we will do the same with every connected component of it. This will make the mentioned Chern class numerically trivial already on the surface itself (not just after the push-forward to $X$).
Lemma 4.22.2. We may assume that $u$ is represented by the class of a smooth surface $S$ on $X$, and for each component $S_l$ of $S$, we have $\deg(c_2(N_{S_l} \subset X) \cdot [S_l]) = 0 \in \mathbb{P}$. 

Proof. By Lemma 4.22.1, we may assume that $u$ is represented by the class of a disjoint union of smooth complete intersections: $u = [S] = \coprod S_l$ with $\deg(c_2(N_{S_l} \subset X) \cdot [S]) = 0$. Let $S_l$ be represented by the intersection $x_1 x_2 x_3$ of very ample divisors. Let $R_{i,j} \subset X$ be the complete intersection $x_i^2 x_j^2$ where one copy of $x_i$ and $x_j$ is the same as in $S_l$, but the other copy is generic, so that $R_{i,j}$ meets $S_l$ at a zero-cycle $x_i^2 x_j^2 x_m$ (where $\{m\} = \{1,2,3\} \setminus \{i,j\}$), and does not meet other components of $S$. Let $R = \coprod_{(i,j) \in \mathcal{I}_2} R_{i,j}$ (we may make components disjoint). Note that $[R \cap S]$ represents the class $c_2(N_{S_l} \subset X)$ on $S_l$. Let $\pi : \tilde{X} \to X$ be the blow-up at $R$, where $E_{i,j} \to R_{i,j}$ are the components of the special divisor, $\rho_{i,j} = [E_{i,j}]$ and $\rho = \sum_{i,j} \rho_{i,j}$. Let $\tilde{S}_l \to S_l$ be the proper transform of $S_l$.

The Chern roots of $N_{\tilde{S}_l} \subset \tilde{X}$ are $x_i + \sum_{j \neq i} \rho_{i,j}, i = 1,2,3$. Moreover, $\tilde{S}_l$ is still a complete intersection: $\tilde{S}_l = \coprod (x_i + \sum_{j \neq i} \rho_{i,j})$, and on $\tilde{S}_l$ we have identities $x_i \cdot \rho_{i,j} = 0$, and $\rho_{i,j}^2 = -\pi_\ast [R_{i,j} \cap S_l]$ and $\rho_{i,j} = 0$ for $\{i,j\} \neq \{i',j'\}$. Then, on $\tilde{S}_l$,
\[
\deg(c_2(N_{\tilde{S}_l} \subset \tilde{X}) \cdot [\tilde{S}_l]) = -\sum_{i,j} \deg([Q_{i,j}]) = -\deg(c_2(N_{S_l} \subset X) \cdot [S_l]).
\]

Let $Q_{i,j} \subset S_l \cap R_{i,j}$. By [5, Theorem 6.7], $\pi^\ast([S_l]) = \tilde{S}_l + [V]$, where $V = \coprod_{(i,j) \in \mathcal{I}_2} [V_{i,j}]$, $V_{i,j} = \mathbb{P}^2_{Q_{i,j}}$ given by $\rho \cdot \pi_{i,j}^\ast(Q_{i,j})$ and contained in the $\mathbb{P}^2$-bundle $E_{i,j} \to R_{i,j}$ is a complete intersection $-\rho_{i,j}^2 x_m$ (as above). We can move the class $[Q_{i,j}]$ along $R_{i,j}$ and so make $\mathbb{P}^2_{Q_{i,j}}$ disjoint from $\tilde{S}_l$ (and it is automatically disjoint from the other components of $S$). The Chern roots of $N_{V \subset \tilde{X}}$ are $-\rho, 0, \rho$, so
\[
\deg(c_2(N_{V \subset \tilde{X}}) \cdot [V]) = -\sum_{i,j} \deg([Q_{i,j}]) = -\deg(c_2(N_{S_l} \subset X) \cdot [S_l]).
\]

Let $P_{i,j}$ be the $(p-1)$ (disjoint) copies of $\mathbb{P}^1_{Q_{i,j}}$ contained in $\pi_{i,j}^\ast(Q_{i,j})$ but not in $\mathbb{P}^2_{Q_{i,j}}$. Let $P = \coprod_{(i,j)} P_{i,j}$ and $\mu : \tilde{X} \to \tilde{X}$ be the blow-up at $P$. Let $G = \coprod_{(i,j)} G_{i,j}$ be the special divisor of $\mu$, with projections $\mu_{i,j} : G_{i,j} \to P_{i,j}$ and $\alpha = c_1(O(1)) = -[G]$. Let $\tilde{V}_{i,j}$ be the proper transform of $V_{i,j}$, and $F_{i,j} = \mu_{i,j}^\ast(\mathbb{P}^2_{Q_{i,j}} \cap P_{i,j}) \cdot \alpha$ (which is isomorphic to the disjoint union of $(p-1)$ copies of $\mathbb{P}^2_{Q_{i,j}}$) whose class is given by $-\alpha \cdot \alpha \cdot \rho_{i,j}$. Let $F = \coprod_{(i,j)} F_{i,j}$. By [5, Theorem 6.7], $\mu^\ast([V_{i,j}]) = [\tilde{V}_{i,j}] + [F_{i,j}]$. The Chern roots of $N_{\tilde{V}_{i,j} \subset \tilde{X}}$ are $-\rho, \rho, 0$. Hence,
\[
\deg(c_2(N_{\tilde{V}_{i,j} \subset \tilde{X}}) \cdot [\tilde{V}_{i,j}]) = (\alpha^2 - \rho^2 + \alpha \rho) \cdot [\tilde{V}_{i,j}] = ((p-1)(1+1) + 0) \cdot \mu_\ast q = 0,
\]
where $q$ is the class of a section $Q_{i,j} \to V_{i,j} = \mathbb{P}^2_{Q_{i,j}}$. The Chern roots of $N_{F_{i,j} \subset \tilde{X}}$ are $-\alpha, 0, \rho$. Therefore, the degree of $c_2(N_{F \subset \tilde{X}}) \cdot [F] = -\deg(-\alpha^2 \cdot [F]) = -(p-1) \sum \deg([Q_{i,j}]) = \deg(c_2(N_{S_l} \subset X) \cdot [S_l])$.

Let us apply the above construction to every component $S_l$ of $S$ and denote the respective objects by the subscript $l$. Now, after applying $\mu_\ast \pi^\ast$, the degree of $c_2(N_{S_l} \subset X) \cdot [S]$ is concentrated in the $F$-components, where $[F_l]$ is given by $-\alpha_l \cdot \alpha_l \cdot \rho_l$. Then
$[F] = \sum l(-\alpha_l \cdot \alpha_l \cdot \rho_l)$. But because $\rho_l \cdot \alpha_l = 0$, and $\alpha_l \cdot \alpha_l = 0$, for $l \neq k$, this can be rewritten as $-\bar{\alpha} \cdot \bar{\alpha} \cdot \bar{\rho}$, where $\bar{\alpha} = \sum \alpha_l$ and $\bar{\rho} = \sum \rho_l$. We can substitute $-\bar{\alpha}, \bar{\alpha}$ and $\bar{\rho}$ by very ample divisors and represent $[F]$ by (the class of) a smooth connected surface with the same $\deg(c_2(N_{F \subset X}) \cdot [F])$, not meeting other components of $S$. Now, the whole degree of $c_2(N_{S \subset X}) \cdot [S]$ is concentrated in a single component $F$. But, by Lemma 4.22.1, this total degree is zero.

Lemma 4.22.2 is proven.

Now we can finish the proof of Proposition 4.22. By Lemma 4.22.2, we may assume that $u$ is represented by the class of a smooth surface $S$ with $c_2(N_{S \subset X}) \sim 0$ on $S$.

Let $\pi : \tilde{X} \rightarrow X$ be the blow-up at $S$, with the special divisor $E \rightarrow X$ and $\rho = c_1(O(1)) = -[E]$. Let $c_l = \pi^{*}_l c_1(N_{S \subset X})$. By [5, Proposition 6.7], $\pi^{*}([S]) = (\rho^2 + c_1 \rho) \cdot [E]$ in $Ch_{k/k}(\tilde{X})$, because $c_2(N_{S \subset X}) \sim 0$ on $S$ (and by Corollary 4.17). Being a complete intersection on $E$, this class may be represented by a smooth surface $\bar{S}$ on $E$. Note also that $\rho(\rho^2 + c_1 \rho) \cdot [E] = 0$ and that the Chern roots of $N_{\tilde{S} \subset \tilde{X}}$ are $-\rho, \rho, \rho + c_1$, so the $\deg(c_2(N_{\tilde{S} \subset \tilde{X}}) \cdot [\tilde{S}_i])$ is still zero.

By Statement 6.5 and flexibility of $k$, there is an irreducible divisor $Z$, containing $\tilde{S}$, smooth outside an anisotropic closed subscheme of $\tilde{S}$, and such that the restriction $Ch^*(\tilde{X}) \rightarrow Ch^*(Z \setminus \tilde{S})$ is surjective. Let $\mu : \tilde{X} \rightarrow \tilde{X}$ be the embedded desingularization of $Z$ and $\tilde{S}$ (note that we may assume that no component of $\tilde{S}$ belongs to the singular locus of $Z$, because this locus is anisotropic). Let $\tilde{Z}$ and $\tilde{S}$ be the proper pre-images of $Z$ and $\tilde{S}$, respectively. Then, $\tilde{Z}$ is smooth connected and, modulo anisotropic classes, $\mu^{*}([\tilde{S}])$ is supported on $\tilde{Z}$. Because the maps $Z \setminus \tilde{S} \leftarrow \tilde{Z} \setminus \mu^{-1}(\tilde{S}) \rightarrow \tilde{Z} \setminus \tilde{S}$ induce isomorphisms $Ch_{k/k}(Z \setminus \tilde{S}) \rightarrow Ch_{k/k}(\tilde{Z} \setminus \mu^{-1}(\tilde{S})) \rightarrow Ch_{k/k}(\tilde{Z} \setminus \tilde{S})$, we obtain that the group $Ch_{k/k}(\tilde{Z})$ is generated by the image of $j^{*} : Ch_{k/k}(\tilde{X}) \rightarrow Ch_{k/k}(\tilde{Z})$ and the classes $[\tilde{S}_i]$ of all of the connected components of $\tilde{S}$. Because $\tilde{S} \sim 0$ on $\tilde{X}$, the image of $j^{*}$ is orthogonal to $[\tilde{S}]$ on $\tilde{Z}$. Finally, on $\tilde{Z}$

$$\deg([\tilde{S}] \cdot [\tilde{S}_i]) = \deg([\tilde{S}_i] \cdot [\tilde{S}]) = \deg(c_2(N_{\tilde{S}_i \subset \tilde{X}}) \cdot [\tilde{S}_i]) = \deg(c_2(N_{\tilde{S}_i \subset \tilde{X}}) \cdot [\tilde{S}_i]) = 0,$$

because $c_2(N_{\tilde{S}_i \subset \tilde{X}}) = c_2(N_{\tilde{S}_i \subset \tilde{Z}}) + c_1(N_{\tilde{S}_i \subset \tilde{X}})$, (where $c_1(N_{\tilde{S}_i \subset \tilde{X}}) = \alpha^{*} \rho \in Ch_{k/k}(\tilde{X})$ because $\tilde{S}$ coincides with $\tilde{X}$, $\tilde{X}$ coincides with $X$ and $X$ coincides with $k$ modulo anisotropic subvarieties and $\rho \cdot [\tilde{S}_i] = 0 \in Ch^{*}(\tilde{X})$).

Hence, $[\tilde{S}] \sim 0$ on $\tilde{Z}$. By Proposition 4.21, the class $[\tilde{S}]$ is represented by an anisotropic subvariety on $\tilde{Z}$, and thus on $\tilde{X}$. Proposition 4.22 is proven.

Having treated 2-cycles on 4- and 5-folds, now the general case follows by an easy induction.

**Proposition 4.23.** Let $k$ be a flexible field and $X$ be a smooth projective $k$-variety. If $u \in Ch_2(X)$ is $\sim 0$, then $u = 0 \in Ch_{k/k;2}(X)$. 
Proof. Induction on \( n = \dim(X) \). The case \( n = 2 \) is trivial, and the cases \( n = 3, 4, 5 \) are covered by Propositions 4.15, 4.21 and 4.22, respectively. This gives the base of induction. (step) Let \( \dim(X) > 5 \). By Corollary 6.2, we may assume that \( u \) is represented by a class of a smooth (possibly disconnected) surface \( S \) on \( X \). Let \( \pi : \tilde{X} \to X \) be the blow-up at \( S \), with the special divisor \( E \). Then \( \pi^*(u) \) has support on a smooth divisor \( E \) and is represented there by a class of some surface \( S' \) (possibly nonsmooth). By Statement 6.5 and flexibility of \( k \), there is an irreducible divisor \( Z \), containing \( S' \), smooth outside an anisotropic closed subscheme of \( S' \), such that the restriction \( \text{Ch}^s(\tilde{X}) \to \text{Ch}^s(Z \setminus S') \) is surjective.

Let \( \mu : \overline{X} \to \tilde{X} \) be the embedded resolution of singularities of \( Z \), with \( \overline{Z} \) and \( \overline{S} \) the proper transforms of \( Z \) and \( S' \), respectively. Then \( \overline{Z} \) is a smooth connected divisor on \( \overline{X} \) and \( \mu^*([S']) \) is represented by \([\overline{S}] \in \text{Ch}_{k/\mathbb{C}}^s(\overline{X})\) supported on \( \overline{Z} \) (because the remaining ingredients are anisotropic). Because \( \overline{Z} \), respectively, \( \overline{S} \), coincides with \( Z \), respectively \( S' \), modulo anisotropic subvarieties, the restriction \( \text{Ch}_{k/\mathbb{C}}^2(\overline{X}) \to \text{Ch}_{k/\mathbb{C}}^2(\overline{Z} \setminus \overline{S}) = \text{Ch}_{k/\mathbb{C}}^2(\overline{Z}) \) is surjective (note that \( \dim(\overline{Z}) \geq 5 \)). But \([\overline{S}] \cdot \text{Num}(p) \) 0 on \( \overline{X} \); hence, it is \( \text{Num}(p) \) 0 on \( \overline{Z} \) as well. By inductive assumption, \([\overline{S}] \) is represented by the class of an anisotropic surface on \( \overline{Z} \), and thus on \( \overline{X} \). The induction step and Proposition 4.23 are proven. \( \square \)

4.3.5. Codimension 2-cycles on a 5-fold. The last remaining case of Theorem 4.11 is that of the codimension 2-cycles on a 5-fold. This is, by far, the hardest one and will require various new tools and extensive computations.

Proposition 4.24. Let \( k \) be a flexible field and \( X \) be a smooth projective variety of dimension 5. If \( u \in \text{Ch}^2(X) \) is \( \text{Num}(p) \sim 0 \), then \( u = 0 \in \text{Ch}_{k/\mathbb{C}}^2(X) \).

Proof. By Corollary 6.2, we may assume that \( u \) is represented by the class \([S] = \sum_i x_i y_i\), where \( x_i, y_i \) are classes of very ample divisors. In particular, all of the components of \( S \) are smooth and transversal to each other.

We start by eliminating (numerically) certain zero-dimensional characteristic classes of \( S \). This needs to be done still at the level of the union of complete intersections (before passing to a single component). In the case of a prime 2, we also need to make numerically trivial the square of the first Chern class of \( S \) at this stage.

Lemma 4.24.1. We may assume that \( u \) is represented by the class \([S] \), where components of \( S \) are smooth complete intersections transversal to each other, with \( c_3^2(N_{S \subset X}) \cdot [S] \sim 0 \) and \( c_1 c_2(N_{S \subset X}) \cdot [S] \sim 0 \) on \( X \). For \( p = 2 \), we may assume, in addition, that \( c_1^3(N_{S \subset X}) \cdot [S] \sim 0 \) on \( X \).

Proof. We need to treat separately the case \( p = 2 \) and that of odd primes.

(\( p = 2 \)) Replace \([S] = \sum_i x_i y_i\) by \([S'] = \sum_i (x_i + y_i) x_i + (x_i + y_i) y_i + (x_i + y_i) \) 

\( c_1^3(N_{S' \subset X}) \cdot [S'] = \sum_i (x_i y_i (x_i + y_i)^3 + (x_i + y_i) x_i y_i^3 + (x_i + y_i) y_i x_i^3) = 0 \in \text{Ch}^5(X) \).
On the other hand, \((c_1^3 + c_1 c_2)(N_{S' \subset X}) \cdot [S'] = P^2 P^1([S'])\), where \(P^t\) is the reduced power operation (modulo 2). By Proposition 4.6, because \([S']^{N_{\text{um}}(p)} \sim 0\) on \(X\), so is \(P^2 P^1([S'])\). Thus, \(c_1 c_2(N_{S' \subset X}) \cdot [S']^{N_{\text{um}}(p)} \sim 0\) on \(X\). Finally,

\[
c_1^3(N_{S' \subset X}) \cdot [S'] = \sum_i (x_i y_i (x_i + y_i)^2 + (x_i + y_i) x_i y_i^2 + (x_i + y_i) y_i x_i^2) = 0 \in \text{Ch}^4(X).
\]

(\(p \neq 2\)) In the case of an odd prime, we need to complement the above method with blowing certain zero-cycles on \(S\). This keeps the result in the form of a union of complete intersections, while modifying the degrees of the needed zero-dimensional Chern classes. How exactly it does this is described by the following result.

**Sublemma 4.24.1.1.** Let \(\pi : \tilde{X} \to X\) be a blow-up at a smooth point of degree 1 on \(S\). Then \(\pi^*(|[S]|)\) may be represented by the class of \(S'\), where the components of \(S'\) are smooth complete intersections (transversal to each other), and \(\text{deg}(c_1 c_2(N_{S' \subset \tilde{X}}) \cdot [S']) = \text{deg}(c_1 c_2(N_{S \subset X}) \cdot [S]) - 2\), and \(\text{deg}(c_1^3(N_{S' \subset \tilde{X}}) \cdot [S']) = \text{deg}(c_1^3(N_{S \subset X}) \cdot [S]) - 8\).

**Proof.** Clearly, we may assume that \(S\) consists of a single smooth complete intersection. Let \(E = \mathbb{P}^4\) be the special divisor of \(\pi\) and \(\rho = c_1(\mathcal{O}(1)) = -[E]\). By [5, Theorem 6.7], \(\pi^*([S]) = [\tilde{S}] + [F]\), where \(\tilde{S}\) is the proper transform of \(S\) and \(F = \mathbb{P}^3\) is a divisor on \(E\) given by \(\rho\). We can make \(\tilde{S}\) and \(F\) transversal. If \([S] = xy\), then \(\tilde{S}\) is a complete intersection \(x + \rho)(y + \rho)\), and \(F\) is a complete intersection \(-\rho \cdot \rho\). On \(\tilde{S}\) we have \(\rho \cdot x = \rho \cdot y = 0\), and \(\rho^3\) is the minus class of a point. Then

\[
\begin{align*}
\text{deg}(c_1 c_2(N_{\tilde{S} \subset \tilde{X}}) \cdot [\tilde{S}] + c_1 c_2(N_{F \subset \tilde{X}}) \cdot [F]) &= \text{deg}([\tilde{S}](x + \rho)(y + \rho)(x + y + 2\rho)) \\
&= \text{deg}([\tilde{S}] \cdot (xy(x + y) + 2\rho^3)) = \text{deg}(c_1 c_2(N_{\tilde{S} \subset \tilde{X}}) \cdot [S]) - 2.
\end{align*}
\]

Similarly,

\[
\begin{align*}
\text{deg}(c_1^3(N_{\tilde{S} \subset \tilde{X}}) \cdot [\tilde{S}] + c_1^3(N_{F \subset \tilde{X}}) \cdot [F]) &= \text{deg}([\tilde{S}](x + y + 2\rho^3)) = \text{deg}([\tilde{S}] \cdot ((x + y)^3 + 8\rho^3)) = \text{deg}(c_1^3(N_{\tilde{S} \subset \tilde{X}}) \cdot [S]) - 8.
\end{align*}
\]

Denote as \(c_1^3\) the deg \((c_1^3)(N_{S \subset X})\) and similar for \(c_1 c_2\). For \([S] = \sum_i x_i y_i\), let us denote \([S_{\text{exp}}] = \sum_i (x_i y_i - (x_i + y_i)x_i - (x_i + y_i)y_i + (x_i + y_i)(x_i + y_i))\), which represents the same class. This operation affects the degrees of Chern classes as follows.

**Sublemma 4.24.1.2.** The substitution of \([S]\) by \([S_{\text{exp}}]\) acts on characteristic numbers as follows:

\[
\begin{pmatrix}
(c_1^3) \\
(c_1' c_2')
\end{pmatrix} =
\begin{pmatrix}
20 & -2 \\
5 & 1
\end{pmatrix}
\begin{pmatrix}
(c_1^3) \\
(c_1' c_2')
\end{pmatrix}.
\]

**Proof.** It is sufficient to treat the case of a single complete intersection \([S] = xy\). Then

\[
\begin{align*}
c_1^3 - c_1' &= \text{deg}((x + y)^2 (2x + y)^3 - (x + y)x(2x + y)^3 - (x + y)y(2y + x)^3) \\
&= \text{deg}(xy(x + y)(19(x + y)^2 - 2xy)) = 19c_1^3 - 2c_1 c_2,
\end{align*}
\]
\[ c_1' c_2' - c_1 c_2 = \deg((x + y)^2 (x + y)^3 - (x + y)^2 (2x + y) - (x + y)^2 y^2 (2y + x)) = \deg(5xy(x + y)^3) = 5c_1^3. \]

Now we can combine both methods. Substituting \( S_{\exp} \) and blowing up the zero-cycles \( \frac{5}{2} c_1^3 (N_{S < X}) \) and \( \frac{1}{2} c_1 c_2 (N_{S < X}) \) on it (note that \( p \neq 2 \)), we obtain \([S'] = \pi^*(|S|)\) such that all of the components of \( S' \) are still smooth complete intersections transversal to each other, and by Sublemma 4.24.1.1,

\[
\left( c_1'' \right)^3 = \begin{pmatrix} 0 & -6 \\ 0 & 0 \end{pmatrix} \left( c_1' c_2' \right).
\]

Applying this procedure twice, we obtain \( c_1^3 = 0 \) and \( c_1 c_2 = 0 \). Lemma 4.24.1 is proven.

The next step is to make \( S \) into a single connected component. This will be possible due to the preparations we made (trivial zero-dimensional Chern classes).

**Lemma 4.24.2.** We may assume that \( S \) is smooth connected with \( c_1^3 (N_{S < X}) \cdot |S| \overset{\text{Num}(p)}{\sim} 0 \), \( c_1 c_2 (N_{S < X}) \cdot |S| \overset{\text{Num}(p)}{\sim} 0 \). For \( p = 2 \), we may assume, in addition, that \( c_1^2 (N_{S < X}) \cdot |S| \overset{\text{Num}(p)}{\sim} 0 \).

**Proof.** By Lemma 4.24.1 we may assume that \( S = \bigcup_i S_i \) consists of smooth transversal complete intersections and the needed conditions on the characteristic classes are satisfied. Let \( \pi : \tilde{X} \to X \) be the blow-up at all intersections \( S_i \cap S_j, i \neq j \). Let \( E_{[i,j]} \to S_i \cap S_j \) be the respective component of the special divisor, \( \rho_{[i,j]} = [-E_{[i,j]}] \) and \( \rho = \sum_{[i,j]} \rho_{[i,j]} \). By [5, Theorem 6.7], \( \pi^*|S| = |\tilde{S}| + |F| + |G| \), where \( \tilde{S} = \bigsqcup_i \tilde{S}_i \) is the proper transform of \( S \), and \( F = \bigsqcup_{[i,j]} E_{[i,j]} \), where

\[
|F_{[i,j]}| = (E_{[i,j]} \cdot (\rho_{[i,j]} + \pi_{[i,j]}^*(c_1(N_{S_i < X}) + c_1(N_{S_j < X})))) \quad \text{and} \quad |G| = (-\rho) \cdot \rho.
\]

Let \( S' = \tilde{S} \cup F \cup G \). Here \( \rho_{[i,j]} \) satisfies \( \rho_{[i,j]}^2 + \rho_{[i,j]}^3 (x_i + y_i + x_j + y_j) + x_i y_i x_j y_j = 0 \), where \( |S_k| = x_k y_k \). Of course, one can get rid of the \( G \)-term by considering

\[
|\tilde{F}_{[i,j]}| = |E_{[i,j]}| \cdot (2\rho_{[i,j]} + \pi_{[i,j]}^*(c_1(N_{S_i < X}) + c_1(N_{S_j < X}))).
\]

This will work for odd primes. But for \( p = 2 \), this term really makes a difference.

The following result computes the degrees of characteristic classes of \( \tilde{S}, F, G \) and their intersections in terms of those of \( S \).

**Sublemma 4.24.2.1.**

1. \( \deg(c_1 c_2 (N_{S < X}) \cdot |\tilde{S}|) = 2 \cdot \deg(c_1 c_2 (N_{S < X}) \cdot |S|); \)
2. \( \deg(c_1 c_2 (N_{F < X}) \cdot |F|) = \deg(c_1 c_2 (N_{S < X}) \cdot |S|); \quad \deg(c_1 c_2 (N_{G < X}) \cdot |G|) = 0; \)
3. \( \deg(c_1^3 (N_{S < X}) \cdot |S'|) = \deg((c_1^3 + 4c_1 c_2)(N_{S < X}) \cdot |S|); \)
4. \( \deg(c_1 (N_{S < X}) \cdot |\tilde{S}| \cdot |F|) = -3 \cdot \deg(c_1 c_2 (N_{S < X}) \cdot |S|); \)
5. \( \deg(c_1 (N_{F < X}) \cdot |\tilde{S}| \cdot |F|) = -2 \cdot \deg(c_1 c_2 (N_{S < X}) \cdot |S|). \)

**Proof.** Let \( \rho_i = \sum_{j \neq i} \rho_{[i,j]} \). The Chern roots of \( \tilde{S} \) are \( \rho_i + x_i + y_i \), and the Chern roots of \( F_{[i,j]} \) are \(-\rho_{[i,j]} + x_i + y_i + x_j + y_j \). Denote: \( a_i = x_i + y_i, b_i = x_i y_i, \) and...
\[a_{[i,j]} = a_i + a_j, \quad b_{[i,j]} = b_i b_j.\] Using the equation for \(\rho_{[i,j]}\) and the fact that \(\rho_{[i,j]}\), multiplied by any monomial of degree \(\geq 2\) in \(x\) and \(y\), is zero, we get

\[
\deg(c_1 c_2(N_{S\subset X}) \cdot [\tilde{S}]) = \deg \left( \sum_i (\rho_i + x_i)^2 (\rho_i + y_i)^2 (2\rho_i + a_i) \right) \\
= \deg \left( \sum_i (2\rho_i^5 + 5\rho_i^4 a_i + b_i^2 a_i) \right) \\
= \deg \left( 2 \sum_i b_i^2 a_i - \sum_i b_i a_i \cdot \left( \sum_j b_j \right) \right) = 2 \cdot \deg(c_1 c_2(N_{S\subset X}) \cdot [S]),
\]

because \(\sum_j x_j y_j = [S] \overset{\text{Num}(p)}{\sim} 0\) on \(X\). Analogously,

\[
\deg(c_1 c_2(N_{F\subset X}) \cdot [F]) = \deg \left( \sum_{[i,j]} \rho_{[i,j]}^2 \rho_{[i,j]} + a_{[i,j]}^2 a_{[i,j]} \right) = \deg \left( \sum_{[i,j]} \rho_{[i,j]}^4 a_{[i,j]} \right) \\
= \deg \left( \sum_{i \neq j} -b_i b_j a_i \right) = \deg \left( \sum_i b_i^2 a_i - \left( \sum_i b_i a_i \right) \left( \sum_j b_j \right) \right) = \deg(c_1 c_2(N_{S\subset X}) \cdot [S]),
\]

again because \([S] \overset{\text{Num}(p)}{\sim} 0\) on \(X\). Using the same properties, we obtain

\[
\deg(c_1^3(N_{S\subset X}) \cdot [\tilde{S}]) = \deg \left( \sum_i (ho_i + x_i)(\rho_i + y_i)(2\rho_i + a_i)^3 \right) \\
= \deg \left( \sum_i (8\rho_i^5 + 20\rho_i^4 a_i + b_i a_i^3) \right) \\
= \deg \sum_i (4b_i^2 a_i + b_i a_i^3) - 4 \deg \left( \sum_i b_i a_i \cdot \sum_j b_j \right) \\
= \deg((4c_1 c_2 + c_1^3)(N_{S\subset X}) \cdot [S]), \quad \text{and}
\]

\[
\deg(c_1^3(N_{F\subset X}) \cdot [F]) = \deg \sum_{[i,j]} -\rho_{[i,j]}(\rho_{[i,j]} + a_{[i,j]}) a_{[i,j]}^3 = 0.
\]

Clearly, \(\deg(c_1^3(N_{G\subset X}) \cdot [G]) = 0\) and \(\deg(c_1 c_2(N_{G\subset X}) \cdot [G]) = 0\), because \(c_1(N_{G\subset X}) = 0\). As a result, \(\deg(c_1^3(N_{S\subset X}) \cdot [S']) = \deg((c_1^3 + 4c_1 c_2)(N_{S\subset X}) \cdot [S])\).

Finally, \(\deg(c_1(N_{S\subset X}) \cdot [\tilde{S}] \cdot [F]) =

\[
\deg \sum_{[i,j]} (c_1(N_{S\subset X}) \cdot [\tilde{S}] + c_1(N_{S\subset X}) \cdot [\tilde{S}]) (-\rho_{[i,j]})(\rho_{[i,j]} + a_{[i,j]}) \\
= \deg \left( \sum_{[i,j]} -\rho_{[i,j]}^3 (4\rho_{[i,j]} + 3a_{[i,j]}) (\rho_{[i,j]} + a_{[i,j]}) \right) \\
= \deg \left( \sum_{[i,j]} -\rho_{[i,j]}^4 (4\rho_{[i,j]} + 7a_{[i,j]}) \right) \\
= \deg \sum_{[i,j]} (4\rho_{[i,j]}^4 + 7a_{[i,j]} a_{[i,j]} = 3 \deg \sum_{[i,j]} b_{[i,j]} a_{[i,j]} = -3 \deg(c_1 c_2(N_{S\subset X}) \cdot [S]); \quad \text{and}
\]
Isotropic motives

\[ \deg(c_1(N_{F \subset X}) \cdot [\tilde{S}] \cdot [F]) = \deg \sum_{\{i,j\}} ((\rho_i + x_i)(\rho_i + y_i) + (\rho_j + x_j)(\rho_j + y_j)) \]

\[ \times (-\rho_{[i,j]})(\rho_{[i,j]} + a_{[i,j]}))a_{[i,j]} \]

\[ = \deg \sum_{\{i,j\}} (-2\rho_{[i,j]}^4a_{[i,j]}) = -2\deg(c_1c_2(N_{S \subset X}) \cdot [S]). \]

\[ \square \]

For the prime 2 we also need to control the square of the first Chern class of \( S \).

Sublemma 4.24.2.2. For \( p = 2 \), we have

\[ c_1^2(N_{S \subset X}) \cdot [\tilde{S}] = \pi^*c_1^2(N_{S \subset X}) \cdot [S] \overset{\text{Num}(p)}{\sim} 0 \quad \text{and} \quad c_1^2(N_{F \subset X}) \cdot [F] = 0. \]

\[ \text{Proof.} \] Using the fact that the centers of the blow-up \( \pi \) were one-dimensional, we obtain

\[ c_1^2(N_{S \subset X}) \cdot [\tilde{S}] = \sum_i (\rho_i + x_i)(\rho_i + y_i)(x_i + y_i)^2 = \sum_i x_iy_i(x_i + y_i)^2 = \pi^*c_1^2(N_{S \subset X}) \cdot [S]; \]

\[ c_1^2(N_{F \subset X}) \cdot [F] = \sum_{\{i,j\}} (-\rho_{[i,j]})(\rho_{[i,j]} + x_i + y_i + x_j + y_j)(x_i + y_i + x_j + y_j)^2 = 0. \]

\[ \square \]

We may assume that our class is represented by the class of \( S' = \tilde{S} \cup F \cup G \), where \( \tilde{S} \), \( F \) and \( G \) are smooth (possibly disconnected) and transversal to each other (note that we do not have triple intersections of \( S_i \)'s), and \( [G] = (-\rho) \cdot \rho \), for some divisor \( \rho \). Moreover, both \( \tilde{S} \) and \( F \) have trivial \( c_3 \) and \( c_1c_2 \) characteristic numbers and \( \deg(c_1(N_{S \subset X}) \cdot [\tilde{S} \cap F]) = 0 \) and \( \deg(c_1(N_{F \subset X}) \cdot [\tilde{S} \cap F]) = 0 \). Because components of \( \tilde{S} \), respectively \( F \), are disjoint, by Statement 6.6 there exists a blow-up \( \mu : \tilde{X} \to \tilde{X} \) such that \( \mu^*([\tilde{S}]) \) and \( \mu^*([F]) \) are represented by the classes \([\tilde{S}]\) and \([\tilde{F}]\) of smooth connected transversal subvarieties, such that \( \tilde{S} \cap \tilde{F} = \emptyset \) is connected, with trivial \( c_3 \) and \( c_1c_2 \) characteristic numbers for both \( \tilde{S} \) and \( \tilde{F} \) and with \( \deg(c_1(N_{S \subset X}) \cdot [\tilde{S} \cap \tilde{F}]) = 0 \) and \( \deg(c_1(N_{F \subset X}) \cdot [\tilde{S} \cap \tilde{F}]) = 0 \). For \( p = 2 \), we have, in addition, \( c_1^2(N_{S \subset X}) \cdot [\tilde{S}] \overset{\text{Num}(p)}{\sim} 0 \) and \( c_1^2(N_{F \subset X}) \cdot [\tilde{F}] \overset{\text{Num}(p)}{\sim} 0 \). As a next step, we will combine \( \tilde{S} \cup \tilde{F} \) into a single component. We start with the following general statement about codimension 2 subvarieties on a variety of an arbitrary dimension.

Sublemma 4.24.2.3. Let \( Y = \cup_i Y_i \) be a divisor with strict normal crossings on \( X \) such that \( Y_i \)'s and all of the intersections \( Y_{i,j} = Y_i \cap Y_j \), for \( i \neq j \), are connected. Let \( S = \cup_i S_i \) be a union of smooth transversal components, where \( S_i \subset Y_i \) are divisors. Suppose that \([S_i \cap S_j] \overset{\text{Num}(p)}{\sim} 0 \) on \( Y_{i,j} \). Then \([S] = [S']\), where \( S' = \cup_i S'_i \), with \( S'_i \subset Y_i \) smooth connected and transversal to each other, and all of the intersections \( S'_i \cap S'_j \) anisotropic. This procedure does not change the characteristic classes of \( N_{S \subset X} \) in \( \text{Ch}^*(X) \).

\[ \text{Proof.} \] Adding to \( S_i \) a \( p \)-multiple of a very ample divisor on \( Y_i \), we may assume that \( S_i \) is given by a very ample divisor on \( Y_i \) (this does not change the characteristic classes (mod \( p \))). Let \( S'_i \) be the generic representative of the linear system \([S_i]\). Then \( S'_i \) is connected and, by Statement 6.3, the restriction \( \text{Ch}_2(Y_i \cap Y_j) \to \text{Ch}_0(S'_i \cap S'_j) \) is surjective. This implies that \( S'_i \cap S'_j \) is anisotropic, because \([S_i \cap S_j] \overset{\text{Num}(p)}{\sim} 0 \) on \( Y_i \cap Y_j \). Because \([S_i \to Y_i] \)
is cobordant to \([S_i \to Y_i]\) in \(\Omega^*(Y_i)\), all of the characteristic classes are preserved. Finally, because \(k\) is flexible, we may assume that \(S'\) is defined over \(k\).

Using this result we can make \(\widetilde{S} \cup \overline{F}\) into a single smooth component with the needed Chern classes numerically trivial. This is done with the help of the following statement, specific to dimension 5.

Sublemma 4.24.2.4. Let \(S = S_1 \cup S_2\) with \(S_1, S_2\) smooth connected transversal to each other and connected \(S_{[1,2]} = S_1 \cap S_2\).

1. Suppose that \(\deg(c_1(N_{S_{[1,2]}}) \cdot [S_{[1,2]}]) = 0\), \(\deg(c_1 c_2(N_{S_{[1,2]}}) \cdot [S_1]) = 0\), for \(i = 1, 2\),
   \(\deg(c_1^3(N_{S_{[1,2]}}) \cdot [S]) = 0\), and for \(p = 2\), \(c_2^2(N_{S_{[1,2]}}) \cdot [S] \sim_{\text{Num}} 0\) on \(X\). Then there exists a blow-up \(\epsilon : \hat{X} \to X\) such that \(\epsilon^*([S])\) is represented by the class of a smooth connected subvariety \(\hat{S}\) with \(\deg(c_1 c_2(N_{S_{\hat{X}}}) \cdot [\hat{S}]) = 0\), and for \(p = 2\), \(c_2^2(N_{S_{\hat{X}}}) \cdot [\hat{S}] \sim_{\text{Num}} 0\) on \(\hat{X}\).

2. If \([S] \sim_{\text{Num}} 0\) and \(\deg(c_1 c_2(N_{S_{[1,2]}}) \cdot [S_1]) = 0\), then \(\deg(c_1(N_{S_{[1,2]}}) \cdot [S_{[1,2]}]) = 0\).

Proof. (2) Denote \(N_i = N_{S_{i,[1,2]}}\). Then \(\deg(c_1(N_1) \cdot [S_{[1,2]}]) = \deg(c_1(N_1) \cdot [S_1] \cdot [S_2]) = \deg(c_1(N_1) \cdot [S_1] \cdot [S]) - \deg(c_1(N_1) \cdot [S_1] \cdot [S_1]) = -\deg(c_1 c_2(N_1) \cdot [S_1]) = 0\), as \([S] \sim_{\text{Num}} 0\) and, similarly, \(\deg(c_1(N_2) \cdot [S_{[1,2]}]) = 0\).

Let \(\pi : \tilde{X} \to X\) be the blow-up in the components of \(S\), with the components \(E_i \xrightarrow{\pi_i} S_i\) of the special divisor, and \(\rho_i = -[E_i]\). Note that \(E_1, E_2\) and \(E_{[1,2]} = E_1 \cap E_2\) are connected. Then \(\pi^*([S_1]) = [E_1] \cdot (\rho_1 + \pi_1^* c_1(N_1))\). Consider the classes \([E_1](\rho_1 - \pi_1^* c_1(N_1))\) and \([E_2](\rho_2 + \pi_2^* c_1(N_2))\). We may assume that these classes are represented by the classes of smooth connected subvarieties \(S_1'\) and \(S_2'\), contained in \(E_1\) and \(E_2\), respectively, and transversal to each other and to \(E_{[1,2]}\). Let \(S' = S_1' \cup S_2'\). Then \([S'] = \pi^*([S])\). Using the equation \(\rho_1^2 + \rho_1 \pi_1^* c_1(N_1) + \pi_1^* c_2(N_1) = 0\), on \(E_{[1,2]}\) we get

\[
[S_1' \cap S_2'][E_{[1,2]}] = (\rho_1 - \pi_1^* c_1(N_1)) \times (\rho_1 + \rho_2 + \pi_2^* c_1(N_2))
\]

\[
= \pi_1^* - c_2(N_1) + c_2(N_2) + c_1(N_1) c_1(N_2) + \rho_1 \pi_1^* c_1(N_2) + \rho_2 \pi_2^* c_1(N_1)
\]

where \(\pi_{[1,2]} : E_{[1,2]} \to S_{[1,2]} = S_1 \cap S_2\) is the projection. Here \(S_{[1,2]}\) is a smooth connected curve, with \(\deg(c_1(N_i) \cdot [S_{[1,2]}]) = 0\). Because \(S_{[1,2]}\) is connected, this implies that \([S_1' \cap S_2'] \sim_{\text{Num}} 0\) on \(E_{[1,2]}\).

By Sublemma 4.24.2.3, we can substitute \(S_i'\) by smooth connected \(\tilde{S}_i\), transversal to each other, with anisotropic \(\tilde{S}_1 \cap \tilde{S}_2\), without changing characteristic classes in \(\text{Ch}^*(\tilde{X})\). Let \(\eta : \overline{X} \to \tilde{X}\) be the blow-up in \(\tilde{S}_1, \tilde{S}_2\), with the special divisor \(V\). Here \(V\) is smooth outside an anisotropic subscheme (the intersection of components), so we can treat it as a single component. \(\eta^*([\tilde{S}])\) is represented by the class of a subvariety \(\overline{S}\) of \(V\) whose characteristic classes are \(\eta^*\) of those of \(\tilde{S}\) and that is smooth outside an anisotropic subscheme. Then using Statement 6.5 (with \(V\) treated as a single component) and flexibility of \(k\), we can find an irreducible divisor \(Z\) on \(\overline{X}\), smooth outside an anisotropic subscheme, and containing \(\overline{S}\). Let \(\mu : \hat{X} \to \overline{X}\) be the embedded desingularization of \(Z\) and \(\hat{Z}, S''\) be the
proper pre-images of $Z$ and $\overline{S}$. Because the singularities of $Z$ are anisotropic, the map $\mu^*: \text{Ch}^*_{k/k}(\overline{X}) \to \text{Ch}^*_{k/k}(\hat{X})$ is an isomorphism, and $\mu^*(|S|) = |S''|$. Let $\hat{S}$ be a smooth connected variety representing $|S''|$ on the smooth connected divisor $\hat{Z}$. Because $S''$ is smooth outside an anisotropic subscheme, the characteristic classes of $\hat{S}$ with values in $\text{Ch}^*_{k/k}(\hat{X})$ coincide with $\mu^*$ of those of $\overline{S}$.

It remains to check that the needed characteristic classes of $\hat{S}$ are trivial. Using the fact that $E_{[1,2]}$ is a $\mathbb{P}^1 \times \mathbb{P}^1$-bundle over a curve $S_{[1,2]}$ and the equation $\rho_i^2 + \rho_i \pi_i^* c_1(N_i) + \pi_i^* c_2(N_i) = 0$ on $E_i$, we get

$$\deg(c_1^3(N_{S_{[1,2]}}) \cdot [\hat{S}]) = \deg(c_1^3(N_{S'_{[1,2]}}) \cdot [S'])$$

Similarly,

$$\deg(c_1 c_2(N_{S_{[1,2]}}) \cdot [\hat{S}]) = \deg(c_1 c_2(N_{S'_{[1,2]}}) \cdot [S'])$$

Finally, for $p = 2$, the fact that $c_1^2(N_{S_{[1,2]}}) \cdot [\hat{S}] \overset{\text{Num}(p)}{\sim} 0$ follows from Sublemma 4.24.2.5. □

**Sublemma 4.24.2.5.** In the situation of Sublemma 4.24.2.4, on $\hat{X}$,

$$c_1^2(N_{S_{[1,2]}}) \cdot [\hat{S}] \overset{\text{Num}(p)}{\sim} \varepsilon^*(-2[S_1] \cdot [S_2] + c_1^2(N_{S_{[1,2]}}) \cdot [S]).$$

**Proof.** In the notations of the proof of Sublemma 4.24.2.4, denoting $\nu = \eta \circ \mu$ and using the fact that $E_{[1,2]}$ is a $\mathbb{P}^1 \times \mathbb{P}^1$-bundle over a curve $S_{[1,2]}$, the equation $\rho_i^2 + \rho_i \pi_i^* c_1(N_i) + \pi_i^* c_2(N_i) = 0$ on $E_i$, and [5, Theorem 6.7], we obtain

$$c_1^2(N_{S_{[1,2]}}) \cdot [\hat{S}] = \nu^*(c_1^2(N_{S'_{[1,2]}}) \cdot [S']).$$
\[ v^*([E_1](\rho_1 - \rho_2 + \pi_1^*c_1(N_1))(-\rho_2 + \pi_1^*c_1(N_1))^2 \\
+ [E_2](\rho_2 + \rho_3 + \pi_2^*c_2(N_2)\rho_4 + \pi_2^*c_2(N_2)^2) \\
= v^*([E_1](\rho_2^2(\pi_1^*(3c_1(N_1) + c_1(N_2)) + \rho_1) + \rho_2(-2\pi_1^*c_1(N_1)\rho_1) \pi_1^*c_2(N_1)(\pi_1^*c_1(N_1) + \rho_1)) \\
+ [E_2](\rho_3^2(\pi_2^*(3c_1(N_2) - c_1(N_2)) + \rho_2) + \rho_3(2\pi_2^*c_2(N_2)\rho_2 + \pi_2^*c_2(N_2)^2(\pi_2^*c_1(N_2) + \rho_2)) \\
= v^*(j_{1,2})\pi_1^*(\pi_{1,2}^*(-3c_1(N_1) - 3c_1(N_2))\rho_2 + \pi_{1,2}^*(-3c_1(N_2) + 3c_1(N_1))\rho_1 - 2\rho_1\rho_2) \\
+ \pi^*(c_1^2(N_1)[S_1]) + \pi^*(c_1^2(N_2)[S_2])) \sim v^*\pi^*(c_1^2(N_{S \times X})\cdot [S] - 2[S_1]\cdot [S_2]), \\
\]

because \( c_1(N_1) \sim 0 \) on \( S_{1,2} \) (note that \( S_{1,2} \) is connected). Here \( j_{1,2} : E_{1,2} \to \tilde{X} \) is the closed embedding. 

The subvariety \( \tilde{S} \cup \tilde{F} \) satisfies the conditions of Sublemma 4.24.2.4(1). Thus, we may substitute it by a single connected component and assume that our class is represented by the class of \( T \cup G \), where \( [G] = (-\rho) \cdot \rho \), for some divisor \( \rho \), and \( T \) is a smooth connected subvariety with \( c_1^3(N_{T \times X}) \cdot [T] \sim 0, c_1c_2(N_{T \times X}) \cdot [T] \sim 0 \), and for \( p = 2 \), in addition, \( c_1^2(N_{T \times X}) \cdot [T] \sim 0 \). We may assume \( T \) and \( G \) transversal, with \( G \) and \( T \cap G \) connected. Clearly, \( c_1^3(N_{G \times X}) \cdot [G] \sim 0, c_1c_2(N_{G \times X}) \cdot [G] \sim 0 \), and for \( p = 2 \), \( c_1^2(N_{G \times X}) \cdot [G] \sim 0 \) as well. Because \( [T] + [G] \sim 0 \), applying Sublemma 4.24.2.4(2) and (1) again, we may represent our class by \( [S] \), where \( S \) is smooth connected with \( c_1^3(N_{S \times X}) \cdot [S] \sim 0, c_1c_2(N_{S \times X}) \cdot [S] \sim 0 \), and for \( p = 2 \), in addition, \( c_1^2(N_{S \times X}) \cdot [S] \sim 0 \). Lemma 4.24.2 is proven. 

Now as \( S \) is smooth connected with numerically trivial zero-dimensional Chern classes, we can move up the dimension and make the square of the first Chern class numerically trivial as well. This is already achieved for the prime 2. It remains to treat the odd primes. We will actually make the mentioned \( c_1^2 \) numerically trivial not only on \( X \) but already on \( S \) itself. This will be important for the next step.

**Lemma 4.24.3.** We may assume that \( S \) is smooth connected with \( c_1^3(N_{S \times X}) \cdot [S] \sim 0, c_1c_2(N_{S \times X}) \cdot [S] \sim 0 \) and \( c_1^2(N_{S \times X}) \cdot [S] \sim 0 \) on \( X \). We also may assume that \( c_1^2(N_{S \times X}) \sim 0 \) on \( S \).

**Proof.** By Lemma 4.24.2, we have all of the needed conditions, aside from that on \( c_1^2 \). Let us first make \( c_1^2(N_{S \times X}) \cdot [S] \sim 0 \) on \( X \). For \( p = 2 \) we already have it by Lemma 4.24.2. (\( p \neq 2, 3 \)) Let \( \pi : \tilde{X} \to X \) be the blow-up in the smooth connected complete intersection \( \tilde{R} = \frac{1}{2}c_1(N_{S \times X}) + \frac{1}{3}c_1(N_{S \times X}) \) (of very ample divisors on \( S \)). Let \( E \) be the special divisor of \( \pi \), and \( \rho = -[E] \). Then \( \pi^*[S] = [\tilde{S}] + [F], \) where \( \tilde{S} \) is the proper transform of \( S \) and \( F \) is a smooth connected (very ample) divisor on \( E \), transversal to \( \tilde{S} \), with connected \( \tilde{S} \cap F \) and with \( [F] = [E](\rho + \pi_E^*c_1), \) where \( c_1 = c_1(N_{S \times X}) \). Also, \( c_1(N_{\tilde{S} \times X}) = 2\rho + \pi_{\tilde{S}}^*c_1 \) and \( c_1(N_{F \times X}) = \pi_E^*c_1, \) where \( \pi_S : \tilde{S} \to S \) and \( \pi_E : E \to R \) are natural projections. Because \( \rho \)
Let \( X \) be a smooth connected subvariety on \( \mathbb{P}^1 \) that satisfies the equation
\[
\text{deg}(\pi^*c_1) = 3. 
\]
again because \( c_1 \sim 0 \) on \( \tilde{S} \), as we saw above, and \([S]c_1 = 0\), by assumption,
\[
c_1(\pi^*c_1) \cdot F = [E]\pi^*c_1(\pi^*c_1) = 0,
\]
again because \( \dim(R) = 1 \) and \( c_1 \sim 0 \) on \( R \). Using the same arguments,
\[
c_1c_2(\pi^*c_1) \cdot \tilde{S} = [E]\pi^*c_1(\pi^*c_1) \cdot \tilde{S} = 0.
\]
Let \( \varepsilon : \tilde{X} \to X \) be the blow-up from Sublemma 4.24.2.4 applied to \( \tilde{S} \cup F \). Then we get a smooth connected subvariety \( \tilde{S} \) on \( \tilde{X} \) such that \( c_1(\pi^*c_1) \cdot \tilde{S} = 0 \) and \( c_1c_2(\pi^*c_1) \cdot \tilde{S} = 0 \). Finally, by Sublemma 4.24.2.5,
\[
c_1(\pi^*c_1) \cdot \tilde{S} = \varepsilon^*(c_1(\pi^*c_1) \cdot \tilde{S}) + c_1(\pi^*c_1) \cdot [F] \sim 0.
\]
The case \( \mathbf{p \neq 2,3} \) is done.

\( \mathbf{p = 3} \) Let \( d_1 = c_1^2 + c_2 \) be the characteristic class of degree 2 corresponding to the reduced power operation \( P^1 : \text{Ch}^* \to \text{Ch}^{*+2} \) (modulo 3). Because \([S]\sim 0\), by Proposition 4.6, \( d_1(\pi^*c_1) \cdot [S] = 0 \) as well. On the other hand, \( c_2(\pi^*c_1) \cdot [S] = 0 \). Hence, \( c_1^2(\pi^*c_1) \cdot [S] \sim 0 \). Finally, by Sublemma 4.24.2.5,
\[
c_1(\pi^*c_1) \cdot \tilde{S} = \varepsilon^*(c_1(\pi^*c_1) \cdot \tilde{S}) + c_1(\pi^*c_1) \cdot [F] \sim 0.
\]
Thus, we managed to make \( c_2(\pi^*c_1) \cdot [S] \sim 0 \), while keeping \( c_1^2(\pi^*c_1) \cdot [S] \sim 0 \) and \( c_1c_2(\pi^*c_1) \cdot [S] \sim 0 \). Let us now make the complete intersection \( c_1(\pi^*c_1) \cdot c_1(\pi^*c_1) \) on \( S \) anisotropic.

By blowing up \( S \), we may assume that \( S \subset Y \), where \( Y \) is smooth connected divisor on \( X \). Note that the new \( c_1^3c_1 \) and \( c_1^2 \) characteristic classes are the pull-backs of the old ones and so are still numerically trivial. By Statement 6.5 and flexibility of \( k \),
there exists an irreducible and smooth outside an anisotropic subscheme (of $S$) divisor $Z$ containing $S$, such that the restriction $\text{Ch}^1(X) \to \text{Ch}^1(Z\setminus S)$ is surjective. Let $\pi : \widetilde{X} \to X$ be an embedded desingularisation of $Z$ and $S$, with proper pre-images $\widetilde{Z}$ and $\widetilde{S}$, which are smooth connected varieties. Because singularities were anisotropic, the maps $\pi^* : \text{Ch}^1_{k/k}(X) \isom \text{Ch}^1_{k/k}(\widetilde{X})$ and $\pi_{k/k}^* : \text{Ch}^1_{k/k}(Z\setminus S) \isom \text{Ch}^1_{k/k}(\widetilde{Z}\setminus \widetilde{S})$ are isomorphisms, so the restriction $\text{Ch}^1_{k/k}(\widetilde{X}) \to \text{Ch}^1_{k/k}(\widetilde{Z}\setminus \widetilde{S})$ is surjective as well. Thus, the group $\text{Ch}^1_{k/k}(\widetilde{Z})$ is generated by the image of $j^* : \text{Ch}^1_{k/k}(\widetilde{X}) \to \text{Ch}^1_{k/k}(\widetilde{Z})$ and the class $[\widetilde{S}]$. In addition, on $\widetilde{X}$, the classes $c_1^2(N_{\widetilde{S}\subset \widetilde{X}}) \cdot [\widetilde{S}]$, $c_1c_2(N_{\widetilde{S}\subset \widetilde{X}}) \cdot [\widetilde{S}]$ and $c_1^2(N_{\widetilde{S}\subset \widetilde{X}}) \cdot [\widetilde{S}]$ are $\Num(p)$ equi $0$. Because $c_1^2(N_{\widetilde{S}\subset \widetilde{X}}) \cdot [\widetilde{S}] \Num(p)$ $0$ on $\widetilde{X}$ and $c_1(N_{\widetilde{S}\subset \widetilde{X}})$ is in the image of $j^*$. Hence, $c_1^2(N_{\widetilde{S}\subset \widetilde{X}}) \cdot [\widetilde{S}] \Num(p)$ $0$ already on $\widetilde{Z}$. Because this class is a complete intersection on $\widetilde{Z}$, the intersection of generic representatives of the respective (very ample) linear systems is anisotropic by Statement 6.3. The respective subvariety $S$ is smooth connected, and $c_1$ characteristic classes are preserved. Because $k$ is flexible, we may assume that our varieties are defined over $k$. Lemma 4.24.3 is proven.

In order to apply Corollary 6.12 and finish the proof of Proposition 4.24, it remains to terminate numerically the first Chern class of our $S$.

**Lemma 4.24.4.** We may assume that $S$ is smooth connected and $c_1^m(N_{S\subset X}) \cdot [S] \Num(p)$ $0$, for $m \geq 0$.

**Proof.** By Lemma 4.24.3, we may assume that $S$ is smooth connected variety with the numerically trivial $c_1$, $c_1c_2$ and $c_1^2$ characteristic classes. It remains to make $c_1$ numerically trivial. We need to treat separately the case $p = 2$ and that of odd primes.

**($p \neq 2$)** Let $R$ be the generic representative of the (very ample) linear system $[\frac{1}{2}c_1(N_{S\subset X})]$ on $S$. It is a smooth connected surface and, by Statement 6.3, we have the surjection $\text{Ch}^1(S) \to \text{Ch}^1(R)$. Because $k$ is flexible, we may assume that it is defined over $k$. Let $\pi : \widetilde{X} \to X$ be the blow-up at $R$, with the special connected divisor $E$ and $\rho = -[E]$. Then $\pi^*([S]) = [\widetilde{S}] + [F]$, where $\widetilde{S}$ is the proper pre-image of $S$ and $F$ is a smooth connected divisor on $E$ transversal to $\widetilde{S}$, with connected $\widetilde{S} \cap F$ and with $[F] = [E](\rho + \pi_E^*c_1)$, where $c_1 = c_1(N_{S\subset X})$. We have

$$
c_1(N_{\widetilde{S}\subset \widetilde{X}}) \cdot [\widetilde{S}] + c_1(N_{\widetilde{F}\subset \widetilde{X}}) \cdot [F] = [\widetilde{S}](2\rho + \pi_{\widetilde{S}}^*c_1) + [E](\rho + \pi_E^*c_1)\pi_E^*c_1
$$

because, on $\widetilde{S} \equiv S$, $\rho = -[R]$, and $c_1 \cdot [R] \Num(p)$ $0$ on $R$, as $c_1^2(N_{S\subset X}) \Num(p)$ $0$ on $S$ and $\text{Ch}^1(S) \to \text{Ch}^1(R)$. On the other hand, on $R = \widetilde{S} \cap E$,

$$
[\widetilde{S}] \cdot [F] = [\widetilde{S}](\rho + c_1) = [R](\frac{1}{2}c_1) \Num(p) 0,
$$
and, moreover, we may assume the intersection  $\overline{S} \cap F$ to be anisotropic. By Statement 6.6, there exists a blow-up $\mu : \overline{X} \to \overline{X}$ such that $\mu^*([\overline{S} \cup F])$ is represented by the class of a smooth connected subvariety $\overline{S}$ and such that the characteristic classes of $\overline{S}$ in $\text{Ch}^*_{k/k}$ are $\mu^*$ of the respective classes of $\overline{S} \cup F$. In particular, the $c_1$-class of it is numerically trivial.

It remains to check $c_1^3$ and $c_1^4$ characteristic classes of $\overline{S} \cup F$. We have

$$c_1^3(N_{\overline{S} \subset \overline{X}}) \cdot [\overline{S}] + c_1^4(N_{F \subset \overline{X}}) \cdot [F] = [\overline{S}] (2 \rho + \pi_S^* c_1)^2 + [E] (\rho + \pi_E^* c_1) \pi_E^* c_1^2$$

$$= [E] (\rho + \pi_E^* c_1) \pi_E^* c_1^2 \overset{\text{Num}(p)}{\sim} 0$$

on $\overline{X}$, because $(2 \rho + \pi_S^* c_1) = 0$ on $\overline{S}$, and $\text{deg}(c_1^3(N_{S \subset X}) \cdot [S]) = 0$ while $R$ is connected. Similarly,

$$c_1^3(N_{\overline{S} \subset \overline{X}}) \cdot [\overline{S}] + c_1^4(N_{F \subset \overline{X}}) \cdot [F] = [\overline{S}] (2 \rho + \pi_S^* c_1)^3 + [E] (\rho + \pi_E^* c_1) \pi_E^* c_1^3 = 0,$$

by the same and dimensional reasons. The case $(p \neq 2)$ is done.

$(p = 2)$ The characteristic class $c_1$ corresponds to the reduced power operation $P^1 : \text{Ch}^* \to \text{Ch}^{*+1}$ (modulo 2). Because $[S] \overset{\text{Num}(p)}{\sim} 0$, by Proposition 4.6, $c_1(N_{S \subset X}) \cdot [S] = P^1 ([S]) \overset{\text{Num}(p)}{\sim} 0$ as well. Lemma 4.24.4 is proven.

Proposition 4.24 now follows from Corollary 6.12 and flexibility of $k$. □

Because Conjecture 4.7 was established for all varieties of dimension $\leq 5$, from the existence of push-forward and pull-back structure we obtain that isotropic Chow groups form a quotient of the third theory of higher type associated to $\text{Ch}$.

**Proposition 4.25.** Let $k$ be a flexible field. The projection $\text{Ch}^* \to \text{Ch}^*_{k/k}$ factors through $\text{Ch}^*_{(3)}$.

**Proof.** A class $u \in \text{Ch}^*(X)$ is $= 0 \in \text{Ch}^*_{(3)}$ if it can be presented as $f_* (y \cdot g^*(v))$, where $X \leftarrow X \times Q \overset{g}{\to} Q$ are natural projections, $Q$ is a smooth projective variety of dimension 5, $y \in \text{Ch}^*(X \times Q)$ and $v \in \text{Ch}^*(Q)$ is $\overset{\text{Num}(p)}{\sim} 0$. Then, by Proposition 4.15, Corollary 4.17, Proposition 4.18, Proposition 4.22 and Proposition 4.24, $v = 0 \in \text{Ch}^*_{k/k}(Q)$, so $u = 0 \in \text{Ch}^*_{k/k}(X)$. □

5. **Thick local categories**

In this section we extend the definition of local motivic category to arbitrary finite coefficients $\mathbb{Z}/n$ and introduce the *thick* versions of it, which have better conservativity properties.

**Definition 5.1.** Let $n \in \mathbb{N}$. Let $P$ and $Q$ be smooth varieties of finite type over $k$. We say that $X_Q \overset{n}{\sim} X_P$ if $P$ is $n$-isotropic over every generic point of $Q$, and $Q$ is $n$-anisotropic over some generic point of $P$.

Let $E/k$ be some finitely generated extension and $P$ be a smooth connected variety with $k(P) = E$. Let $Q^n$ be the disjoint union of all smooth connected varieties $Q$ of finite
Generalising Definition 2.3, we can define the \textit{local motivic category with }\mathbb{Z}/n\text{-coefficients}.

**Definition 5.2.** The local motivic category with \(\mathbb{Z}/n\)-coefficients
\[
\text{DM}(E/k; \mathbb{Z}/n) := \mathcal{L}_Q^n \otimes \text{DM}(k; \mathbb{Z}/n).
\]

If we are interested in a \(p\)-localised situation, we can define the \textit{thick local motivic categories}.

**Definition 5.3.** The \(p\)-local motivic category of thickness \(r\) and \(F\)-coefficients
\[
\text{DM}((E/k)^r; F) := \mathcal{L}_P^r \otimes \text{DM}(k; F).
\]

In particular, the local category with \(\mathbb{Z}/p^r\)-coefficients \(\text{DM}(E/k; \mathbb{Z}/p^r)\) is the \(p\)-local motivic category of thickness \(r\) and \(\mathbb{Z}/p^r\)-coefficients \(\text{DM}((E/k)^r; \mathbb{Z}/p^r)\).

Because \(\mathcal{L}_Q^n \supset \mathcal{L}_P^n\) implies that \(\mathcal{L}_Q^m \supset \mathcal{L}_P^n\) for \(m|n\), we get natural functors
\[
\text{DM}(E/k; \mathbb{Z}/n) \to \text{DM}(E/k; \mathbb{Z}/m) \quad \text{and} \quad \text{DM}((E/k)^r; F) \to \text{DM}((E/k)^s; F),
\]
for any \(r \geq s\) and \(m|n\), commuting with the natural functors \(\varphi_E^{\mathbb{Z}/n} : \text{DM}(k; \mathbb{Z}/n) \to \text{DM}(E/k; \mathbb{Z}/n)\).

In the usual way, we can introduce \textit{local geometric motives}, \textit{local Chow motives} and \textit{local Chow groups}. Exactly as in Proposition 2.16 we get the description of \textit{isotropic Chow groups}.

**Proposition 5.4.**
\[
\text{CH}_{k/k}(X; \mathbb{Z}/n) = \text{CH}(X; \mathbb{Z}/n)/(n\text{-anisotropic classes}).
\]

Similarly, for the \textit{thick local Chow groups}, we have
\[
\text{CH}_{(k/k)^r}(X; F) = \text{CH}(X; F)/(p^r\text{-anisotropic classes}).
\]

Because every \(n\)-anisotropic class is numerically equivalent to zero modulo \(n\), we obtain the surjection
\[
\text{CH}_{k/k}(X; \mathbb{Z}/n) \twoheadrightarrow \text{CH}_{Num}(X; \mathbb{Z}/n). \quad (1)
\]

**Question 5.5.** Let \(k\) be flexible. Is it true that \(\text{CH}_{k/k}(X; \mathbb{Z}/p^r) = \text{CH}_{Num}(X; \mathbb{Z}/p^r)\)?

Using the arguments of Proposition 4.15 and Corollary 4.17, we see that the answer is positive for divisors and for zero-cycles. In particular, the projection \(\text{CH}(X; \mathbb{Z}/p^r) \to \text{CH}_{k/k}(X; \mathbb{Z}/p^r)\) factors through \(\text{CH}_{alg}(X; \mathbb{Z}/p^r)\). In addition, it is easy to see that it is true for cycles of dimension 1, provided \(p > 2\), so the mentioned projection factors through \(\text{CH}_{(2)}(X; \mathbb{Z}/p^r)\), in this case.
With the increase of $r$ (and fixed $s$), the family of functors
\[ \varphi_{E}^{r; Z/p^{s}} : \text{DM}(k; Z/p^{s}) \to \text{DM}((E/k)^{r}; Z/p^{s}), \]
for all f.g. extensions $E/k$, becomes more and more conservative. But the target categories are getting more complicated. At the same time, the categories $\text{DM}(E/k; Z/p^{r})$ (that is, $r = s$) should be simpler, and the natural strategy to improve conservativity is to pass to $Z(p)$-coefficients.

The local motivic category with $Z(p)$-coefficients $\text{DM}(E/k; Z(p))$ should be the local category of $\infty$ thickness $\text{DM}((E/k)^{\infty}; Z(p))$. This should be defined as a limit $\varprojlim \text{DM}(E/k; Z(p))$ of categories of finite thickness and will be considered in a separate paper.

6. Auxiliary results

6.1. Up to blow-up, Chow ring of a variety is generated by divisors

The following result is crucial for most of our constructions.

**Theorem 6.1.** Let $X$ be a smooth projective variety and $y \in \text{CH}^{r}(X)$. Then there exists a blow-up $\pi : \tilde{X} \to X$ such that $\pi^{*}(y)$ is a $Z$-polynomial in divisor classes.

**Proof.** Induction on the dim($X$). Below we will denote this induction as $\text{Ind}_{1}$.

(Ind$_{1}$ base) dim($X$) = 0. Nothing to check.

(Ind$_{1}$ step) We can assume that $r > 0$. Then $y$ has support on some divisor. By blowing $X$ up we can assume that this divisor has strict normal crossings, and by the following lemma we can assume that $y$ has support on a smooth divisor $D$.

**Lemma 6.1.1.** If $y = \sum_{i} y_{i}$, and the statement is true for each $y_{i}$, then it is true for $y$.

**Proof.** Suppose, for each $i$, there exists such a blow-up $\pi_{i} : \tilde{X}_{i} \to X$ that $\pi_{i}^{*}(y_{i})$ is a polynomial in divisorial classes. Then, by the results of Hironaka [7], there exists a blow-up $\pi : \tilde{X} \to X$ that covers $\pi_{i}$, for each $i$. Then, clearly, $\pi^{*}(y)$ is a polynomial in divisorial classes.

Let now $j_{D} : D \to X$ be a smooth divisor and $y$ is supported on $D$. Let us say that the pair $(D, X)$ has a special structure with the base $B$ if $D$ is a consecutive projective bundle over $B$ where the canonical line bundles $O(1)$ of all of these fibrations are the restrictions of some line bundles from $X$. Every pair $(D, X)$ possesses a ‘trivial’ special structure with the base $B = D$. We will prove our statement by the induction on the dim($B$). We will denote this induction as $\text{Ind}_{2}$ below.

(Ind$_{2}$ base) dim($B$) = 0. Then $D$ is a disjoint union of consecutive projective bundles whose canonical bundles $O(1)$ are restrictions of some line bundles from $X$. Then $\text{CH}^{*}(D)$ is generated by $j_{D}^{*}(c_{1}(L))$, for some line bundles $L$ on $X$. Because $y = (j_{D})_{*}(\overline{y})$, for some $\overline{y} \in \text{CH}^{*}(D)$, it is a polynomial in divisorial classes.
We have $y = (j_D)_* (\overline{\eta})$, where $\overline{\eta} = \sum_i \varepsilon^* (u_i) \cdot r_i$ with $u_i \in \text{CH}^*(B)$, $\varepsilon : D \to B$ is the natural projection, and $r_i$ is a monomial in $\rho_i s$, where $\rho_i = c_1 (O(1))_t$ is the restriction of some divisorial class from $X$. By Lemma 6.1.1, we can assume that $\overline{\eta} = \varepsilon^* (u)$, where $u \in \text{CH}^* (B)$.

Because $\dim(B) < \dim(X)$, by the inductive assumption of Ind$_1$, there exists a blow-up $\tau : \tilde{B} \to B$, such that $\tau^*(u)$ is a polynomial in divisorial classes. We have a Cartesian diagram of blow-ups:

$$
\begin{array}{ccc}
\tilde{D} & \xrightarrow{\tau_D} & D \\
\downarrow \phi & & \downarrow \varepsilon \\
\tilde{B} & \xrightarrow{\tau} & B
\end{array}
$$

Let $\varphi : \tilde{X} \to X$ be a blow-up of $X$ in the same centers as $\tau_D$, and $j_{\tilde{B}} : \tilde{B} \to \tilde{X}$. Then $\varphi^* ((j_D)_* \varepsilon^* (u)) = (j_{\tilde{B}})_* \tau_D^*(\varepsilon^* (u)) + \sum_m v_m$, where $v_m$ are supported on the components $\tilde{E}_m$ of the special divisor $\tilde{E} = \cup_m \tilde{E}_m$ of the blow-up $\varphi$ (see [5, Theorem 6.7] or [16, Proposition 5.27]). Let $X_m$ be a variety obtained after $m$ blow-ups with the special divisor $j_{E_m} : E_m \to X_m$ of the $m$th blow-up and the projection $\varphi_m : \tilde{X} \to X_m$ whose restriction to $E_m$ is the blow-up $\alpha_m : \tilde{E} \to E_m$. Then (again by [5, Theorem 6.7]), the image of

$$(\varphi^*_m (j_{E_m})_* - (j_{\tilde{E}_m})_* \alpha^*_m) : \text{CH}^*(E_m) \to \text{CH}^*(\tilde{X})$$

has support on $\cup_{n \geq m} \tilde{E}_n$, and the map

$$\oplus \alpha^*_m : \oplus_m \text{CH}^*(E_m) \to \text{CH}^*(\tilde{E})$$

is surjective (because $\cup_{n \geq m} \tilde{E}_n \setminus \cup_{n > m} \tilde{E}_n$ is an open subvariety of $E_m$). Hence, the map

$$\oplus \varphi^*_m (j_{E_m})_* : \oplus_m \text{CH}^*(E_m) \to \text{CH}^*(\tilde{X})$$

covers the image of $(j_{\tilde{E}})_*$.

The pair $(E_m, X_m)$ has a special structure with the base of dimension smaller than $B$ (namely, the center of the $m$th blow-up of $\tau$), where $c_1 (O(1))$ of the external projective fibration is the restriction of $[-E_m]$ from $X_m$, and all of the other (internal) canonical bundles are induced by the special structure on $(D, X)$ and thus are restrictions of some divisorial classes from $X$. By the inductive assumption of Ind$_2$, any element in $(j_{E_m})_* \text{CH}^*(E_m)$ is a polynomial in divisorial classes over some blow-up $\tilde{X}_m \to X_m$. By Lemma 6.1.1, we obtain that $\sum_m v_m$ is a polynomial in divisorial classes over some blow-up of $\tilde{X}$. Hence, it remains to deal with $(j_{\tilde{B}})_* \tau_D^*(\varepsilon^* (u))$.

We know that $\tau_D^*(\varepsilon^* (u)) = \tilde{\varepsilon}^* \tau^*(u)$ is a polynomial in divisorial classes by construction. Let us denote this element again as $\overline{\eta}$ and the divisor (on which it is supported) as $D$. By Lemma 6.1.1, we can assume that $\overline{\eta}$ is a monomial $x_1 \cdots x_{r-1}$ in very ample divisorial classes on $D$. We will use induction on $r$. Below it will be denoted as the Ind$_3$.

**Ind$_3$ base** When $r = 1$ there is nothing to prove as $y = (j_D)_* (\overline{\eta}) = [D]$.

**Ind$_3$ step** Consider the chain of codimension 1 regular embeddings $D \leftarrow Y_1 \leftarrow Y_2 \leftarrow \cdots$, where $[Y_{k+1}]$ represents the restriction of $x_1$ to $Y_k$. Construct the chain of
blow-ups $\overline{X} \leftarrow X_1 \leftarrow X_2 \leftarrow \ldots$ in codimension 2 centers $Z_k \to \overline{X}_{k-1}$ inductively as follows. The special divisor $E_k$ of $\pi_k$ is a consecutive projective line fibration $E_k \xrightarrow{\varphi_k} Y_k$ and $Z_{k+1} = \varphi_k^{-1}(Y_{k+1})$. In particular, $E_k \xleftarrow{\epsilon_k} Z_k$ is a projective line fibration and $\varphi_k = \epsilon_1 \circ \ldots \circ \epsilon_k$. Let $i_k = i_1 \circ \ldots \circ i_k$ and $\overline{y}_k = \varphi_k^*(i_k)^*(\overline{y})$ be the class supported on $E_k$.

Then we have a Cartesian diagram

\[
\begin{array}{ccc}
E_{k+1} & \xrightarrow{iE_{k+1}} & \overline{X}_{k+1} \\
\downarrow & & \downarrow \\
Z_{k+1} & \xrightarrow{a} & \overline{E}_k
\end{array}
\]

with $\overline{E}_k = E_k$ and $\overline{y}_{k+1} = \epsilon_{k+1}^* \alpha^* \overline{y}_k$. By (the Chow group version of) [16, Proposition 5.27], we have

\[
\pi_{k+1}^* ((iE_k)_* \overline{y}_k) = (j_{E_k})_* \overline{y}_k - (iE_{k+1})_* \overline{y}_{k+1}.
\]

Here, by the inductive assumption of Ind$_3$, the first summand $(j_{E_k})_* \overline{y}_k = (j_{E_k})_* (x_1 \cdot x_2 \cdot \ldots \cdot x_{r-1}) = [E_k+1] \cdot (j_{E_k})_* (x_2 \cdot \ldots \cdot x_{r-1})$ is expressible as a polynomial in divisorial classes over some blow-up of $\overline{X}_{k+1}$, so (using Lemma 6.1.1) the question about $\overline{y}_k$ supported on $E_k \to \overline{X}_k$ is reduced to the question about $\overline{y}_{k+1}$ supported on $E_{k+1} \to \overline{X}_{k+1}$. Thus, it is sufficient to show that our statement is true for $\overline{y}_k$ supported on $E_k \to \overline{X}_k$, for at least one $k$. But for $k = \dim(X) - r$, the class $(i_k)^*(\overline{y})$ is zero by dimensional reasons. Hence, the (Ind$_3$ step) is proven. This implies (Ind$_2$ step) and (Ind$_1$ step). The theorem is proven.

\[\square\]

**Corollary 6.2.** Let $X$ be a smooth projective variety and $y \in \text{CH}^r(X)$. Then there exists a blow-up $\pi : \widetilde{X} \to X$, such that $\pi^*(y)$ is represented by a linear combination of classes of smooth complete intersections of very ample divisors that are transversal to each other. In particular, for $r > \dim(X)/2$, it is represented by the difference of classes of two smooth disjoint subvarieties.

### 6.2. General position results

In this section we present various general position arguments that permit replacing cycles by the classes of connected subvarieties and, in some cases, reducing the anisotropy of a class $[S]$ to the numerical triviality of some characteristic classes of $S$.

The following simple and well-known ‘Chow group shadow’ of the Lefschetz theorem is one of our key ingredients.

**Statement 6.3.** Let $X$ be a scheme with a map $X \xrightarrow{f} \mathbb{P}^n$ and $t : D_n \to X$ be the generic hyperplane section of $X$ (over $k((\mathbb{P}^n)^\vee)$). Then the pull-back $t^* : \text{CH}^r(X) \to \text{CH}^r(D_n)$ is surjective. If $X$ is a smooth variety, so is $D_n$.

**Proof.** Consider $Y \subset X \times (\mathbb{P}^n)^\vee$ given by $Y = \{(x, H)|f(x) \in H\}$. Then $Y$ is a projective bundle: $Y = \text{Proj}_X(V)$, where $V = W/O(-1)$ (with $(\mathbb{P}^n)^\vee = \mathbb{P}(W)$). Let $Y_n$ be the generic
fibre of the projection \( Y \to (\mathbb{P}^n)^\vee \). This is the ‘generic’ hyperplane section \( D_\eta \). By the projective bundle theorem and localisation, we have surjections \( \text{CH}^*(X)[\rho] \to \text{CH}^*(Y) \to \text{CH}^*(Y_\eta) \), where \( \rho = c_1(O(1)) \). Because \( \rho \) is the pull-back of the class of a hyperplane on \( (\mathbb{P}^n)^\vee \), it is zero in \( \text{CH}^*(Y_\eta) \). Thus, we get the surjection \( \text{CH}^*(X) \to \text{CH}^*(Y_\eta) \). Finally, if \( X \) is smooth, so are \( Y \) and \( Y_\eta \).

The next result shows that any closed subscheme of an effective Cartier divisor can be made the base set of the respective linear system (which, in turn, can be made very ample), if we modify the divisor by an \( n \)-multiple of some other divisor, for a given natural \( n \).

**Statement 6.4.** Let \( X \) be an irreducible quasi-projective variety and \( n \in \mathbb{N} \). Let \( E \) be an effective Cartier divisor on \( X \) and \( S \subseteq E \) be a closed subscheme. Then there exists a very ample divisor \( D \) such that the linear system \( |E + n \cdot D|_S \) consists of very ample divisors and \( S \) is the base set of \( D \).

**Proof.** There are very ample divisors \( F_1, F_2 \) on \( X \) such that \( [E] = [F_1] - [F_2] \). Then the class \( [E + nF_2] = [F_1 + (n - 1)F_2] = [H] \) is very ample and defines an embedding \( X \hookrightarrow \mathbb{P}^N \). Let \( S \) be the closure of the image of \( S \) in this embedding. The coordinate ring of \( S \) has relations of degree \( \leq m \). In other words, the base set of the linear system \( |kH|_S \) is \( S \), for any \( k \geq m \). Take \( k = nm + 1 \). Then \( |kH| = [(nm + 1)(E + nF_2)] = [E + n(mF_1 + ((n - 1)m + 1)F_2)] = [E + nD] \), where \( D = mF_1 + ((n - 1)m + 1)F_2 \) is very ample.

The following result will enable us to substitute a multicomponent divisor with only \( n \)-anisotropic singularities, which contains a given closed subscheme, by a single component one. The same can be done with a collection of such divisors and subschemes with the result having all of the faces connected, if the original collection of divisors was with strict normal crossings modulo \( n \)-anisotropic subvarieties. This will be our key tool below.

**Statement 6.5.** Let \( n \in \mathbb{N} \), \( X \) be a smooth projective connected variety of dimension \( d \) and \( E = \bigcup_i E_i \) be a divisor on it with strict normal crossings outside an \( n \)-anisotropic closed subscheme, with possibly reducible components \( E_i \), and let \( S_i \subseteq E_i \) be some closed subschemes such that, for any subset \( I \) of the set of indices, \( \dim(S_I) < d - \#(I) \), where \( S_I = \cap_{i \in I} S_i \). Then, over some purely transcendental f.g. extension of \( k \), there is a divisor \( Z = \bigcup_i Z_i \), where \( |Z_i| = |E_i| \in \text{CH}^1(X; \mathbb{Z}/n) \), \( S_i \subseteq Z_i \), for any \( I \), the variety \( Z_I = \cap_{i \in I} Z_i \) is irreducible, and \( Z \) has strict normal crossings outside an \( n \)-anisotropic closed subscheme of \( S \). Moreover, the restriction \( \text{CH}^*(X) \to \text{CH}^*(Z_I \setminus S_I) \) is surjective.

**Proof.** By the Statement 6.4, for any \( i \), there exists a very ample divisor \( D_i \), such that the linear system \( \Phi_i = |E_i + n \cdot D_i|_{S_i} \) consists of very ample divisors and has the base set \( S_i \). Let \( Z_i \) be the generic element of this linear system (defined over \( k(\mathbb{P}(\Phi_i)) \)). Clearly, \( |Z_i| = |E_i| \in \text{CH}^1(X; \mathbb{Z}/n) \) and \( S_i \subseteq Z_i \). Let us show that \( Z_I = \cap_{i \in I} Z_i \) is irreducible. We will prove by induction on \( \#(I) \) that, for any \( i \in I \), the restriction \( \text{CH}^0(Z_I \setminus S_i) \to \text{CH}^0(Z_I) \) is surjective. The (base) \( I = \emptyset \) is empty.
The linear system $\Phi_i$ defines an embedding of $X \setminus S_i$ into a projective space, and for any subscheme $T \subset X$ defined over some field $L$ and $Z_i$ defined over $L(\mathbb{P}(\Phi_i))$ as above, we have $\dim(T \cap (Z_i \setminus S_i)) \leq \dim(T) - 1$. By Statement 6.3, we have a surjection $\text{CH}^0(Z_i \setminus Z_i \cap S_i) \to \text{CH}^0(Z_i \setminus Z_i \cap S_i)$. We know that all of the components of $Z_i$ have dimensions $\geq d - \#(I)$. On the other hand, the scheme $Z_i \cap S_i$ is the union $\bigcup_{i \in J \subset I} Y_J$, where $Y_J = (\cap_{j \in J} S_i) \cap (\cap_{j \notin I \setminus J} (Z_i \setminus S_j))$. Because $\dim(Y_J) \leq \dim(S_i) - \#(I \setminus J)$, we obtain that $\dim(Z_i \cap S_i) \leq \max(\dim(S_i) - \#(I \setminus J)|i \in J \subset I) < d - \#(I)$. Hence, $\text{CH}^0(Z_i) = \text{CH}^0(Z_i \cap S_i)$, and we get the surjection $\text{CH}^0(Z_i \setminus S_i) \to \text{CH}^0(Z_i)$. The induction step is proven.

Thus, we have the surjection $\text{CH}^0(X) \to \text{CH}^0(Z_i)$, and because $X$ is irreducible, so is $Z_i$.

Our system $\Phi_i$ contains $E_i + |n \cdot D_i|$. The generic representative of $|n \cdot D_i|$ is $n$-anisotropic (by Statement 6.3 and the arguments from the proof of Proposition 4.15). Thus, the generic representative $G_i$ of $E_i + |n \cdot D_i|$ has only $n$-anisotropic singularities and, modulo $n$-anisotropic subvarieties, the divisor $G = \bigcup_i G_i$ has strict normal crossings. Consequently, the generic representative $Z_i$ of our system $|E_i + n \cdot D_i|_Y$ will have only $n$-anisotropic singularities, too, and the divisor $Z = \bigcup_i Z_i$ will have strict normal crossings modulo $n$-anisotropic subvarieties. Indeed, we have a divisor $W$ on $X \times P$, where $P = \prod_i \mathbb{P}(\Phi_i)$ parametrizes (combinations of) elements of our linear systems. The fibre over the generic point of $P$ is $Z$, and the fibre over some special point is $G$. Let $R$ be a discrete valuation ring with the fraction field $K$ and residue field $\kappa$ and $W_R$ be some divisor on $X \times \text{Spec}(R)$, with fibres $W_K$ and $W_\kappa$ over the generic and closed point of $\text{Spec}(R)$, respectively. Having a closed point $T$ of $W_K$, consider the closure of it in $W$. We get a proper morphism $f : T \to \text{Spec}(R)$ of relative dimension zero, whose fibre over $\text{Spec}(\kappa)$ consists of points $t_i$ with multiplicities $e_i$; these are the specialisations of $T$. The specialisation of a singular point is singular, and specialisation of a point where components are not transversal has the same property. At the same time,

$$[k(T) : K] = \sum_i [k(t_i) : \kappa] \cdot e_i.$$  

Therefore, if $[k(T) : K]$ is not divisible by $n$, then one of $[k(t_i) : \kappa]$ is. This shows that $Z$ should be a divisor with strict normal crossings at every point that is not $n$-anisotropic. Because our linear system $\Phi_i$ is very ample on $X \setminus S_i$, the divisor $Z$ has strict normal crossings outside $S$. By the same reason and by Statement 6.3, we have the surjection $\text{CH}^*(X) \to \text{CH}^*(Z_i \setminus S_i)$.

This allows representing some cycles of codimension 2 by single components. Everywhere below we will denote

$$\text{Ch}^*_k(X) := \text{CH}^*(X, \mathbb{Z}/n)/(n - \text{anisotropic classes}),$$

where $n$ is some natural number (which should be clear from context).

**Statement 6.6.** Let $S = \bigcup_i S_i$ be the union of smooth connected transversal subvarieties of codimension 2 on a smooth projective variety and $n \in \mathbb{N}$. Suppose that all of the intersections $S_i \cap S_j$ are $n$-anisotropic. Then over some $f.g.$ purely transcendental
Let irreducible subvarieties, smooth outside $S$ is not 'deform' the chains of codimension 1 embeddings of irreducible varieties.

**Proof.** Let $\pi : \tilde{X} \rightarrow X$ be the blow-up in all of the components $S_i$ of $S$, with $E_i \xrightarrow{\pi_i} S_i$ the components of the special divisor and $\rho_i = -[E_i]$. Then, by [5, Proposition 6.7], $\pi^*(|S|) = [F]$, where $F = \cup_i F_i$, $F_i$ is supported on $E_i$ and $|F_i| = |E_i|\rho_i + \pi^*_i(\mathcal{C}_1(N_{S_i \subset X}))$. Note that $E = \cup_i E_i$ is a divisor with strict normal crossings, with all of the intersections $E_i \cap E_j$ $n$-anisotropic. Note that $c_1(N_{F_j \subset \tilde{X}}) = \pi^*_i(c_1(N_{S_i \subset X}))$ and $c_2(N_{F_j \subset \tilde{X}}) = \pi^*_i(c_2(N_{S_i \subset X}))$. Hence, the same is true about all other characteristic classes.

Because $E$ is smooth outside an $n$-anisotropic subscheme, by Statement 6.5 (where we consider $E$ as a single component), over some f.g. purely transcendental extension of $k$, there is an irreducible divisor $Z$, containing $F$, smooth outside an $n$-anisotropic closed subscheme of $F$. Let $\epsilon : \overline{X} \rightarrow \tilde{X}$ be an embedded desingularisation of $Z$. Let $\overline{Z}$ and $\overline{F}$ be the proper pre-images of $Z$ and $F$. Then $\epsilon^* : \text{Ch}_{k/k}(\tilde{X}) \rightarrow \text{Ch}_{k/k}(\overline{X})$ is an isomorphism and $\epsilon^*(|F|) = |\overline{F}| \in \text{Ch}_{k/k}(\overline{X})$ is supported on the smooth connected divisor $\overline{Z}$. By adding an $n$-multiple of a very ample divisor, we can substitute $|\overline{F}|$ by a very ample divisor on $\overline{Z}$. Let $\overline{S}$ be the generic representative of the linear system $|\overline{F}|$ on $\overline{Z}$. Then $\overline{S}$ is smooth and connected. Because, modulo $n$-anisotropic subvarieties, $\overline{X}$ coincides with $X$ and $\overline{F}$ with $F$, the characteristic classes of $\overline{S}$ in $\text{Ch}_{k/k}(\overline{X})$ are $\epsilon^*$ of the respective classes of $F$.

For the pair of subvarieties $S = \sum_i S_i$ and $T = \sum_j T_j$, consider the blow-up $\pi : \tilde{X} \rightarrow X$ at all components of $S$ and $T$. Then the special divisor $E = E_S \cup E_T$ has strict normal crossings, where $E_S$ and $E_T$ are smooth outside $n$-anisotropic subschemes. Applying Statement 6.5 to $F_S \cup F_T$ contained in $E_S \cup E_T$ (where we consider $E_S$ and $E_T$ as single components), we obtain a divisor $Z = Z_S \cup Z_T$ containing $S \cup T$, with strict normal crossings outside an $n$-anisotropic subscheme, with irreducible $Z_S, Z_T$ and $Z_S \cap Z_T$. Resolving $n$-anisotropic singularities and nontransversalities of $Z$, as above, we obtain the needed smooth connected transversal subvarieties $\overline{S}$ and $\overline{T}$ having the needed characteristic numbers. Because $Z_S \cap Z_T$ is irreducible, the intersection $\overline{S} \cap \overline{T}$ is connected.

The next statement represents an elementary block with the help of which we will 'deform' the chains of codimension 1 embeddings of irreducible varieties.

**Statement 6.7.** Let $n \in \mathbb{N}$, $X$ be projective irreducible variety, smooth outside an $n$-anisotropic closed subscheme, and $S \subset Z \subset X$ be embeddings of codimension 1 of irreducible subvarieties, smooth outside $n$-anisotropic closed subschemes and such that $S$ is not $n$-anisotropic. Then, over some f.g. purely transcendental extension of $k$, there exists $Z'$ such that $S \subset Z' \subset X$ has the same properties, $[Z'] = [Z]$ in $\text{Ch}_{k/k}(X)$, and the restriction $\text{Ch}_{k/k}(X) \rightarrow \text{Ch}_{k/k}(Z' \setminus S)$ is surjective.
Isotropic motives

Proof. This is a particular case of Statement 6.5, aside from the fact that we permit $X$ to have anisotropic singularities. But the same proof works. Outside some closed $n$-anisotropic subscheme $T$ of $X$, $Z$ is a Cartier divisor and, by Statement 6.4, there exists a very ample divisor $D$ on $X \setminus T$, such that the linear system $\Phi = |Z + n \cdot D|_{S, S \cap T}$ on $X \setminus T$ consists of very ample divisors and has the base set $S \setminus T$. This linear system defines an embedding of $X \setminus (S \cup T)$ into a projective space. Let $Z'$ be the closure in $X$ of the generic element of this linear system (defined over $k(\mathbb{P}(\Phi))$). Because $S$ is not $n$-anisotropic, $S \setminus S \cap T$ is nonempty, so $Z'$ contains $S$. Clearly, $|Z'| = |Z| \in \text{Ch}^1_{k/k}(X) = \text{Ch}^1_{k/k}(X \setminus T)$.

By Statement 6.3, we have a surjection $\text{Ch}^*_k(X) \to \text{Ch}^*_k(Z' \setminus S)$, and $Z'$ is irreducible. The same arguments as in the proof of Statement 6.5 show that $Z'$ has only $n$-anisotropic singularities.

The previous result permits deforming the chains of codimension 1 embeddings in such a way that isotropic Chow groups of a term of the new chain would be covered by those of the previous (ambient) term modulo such groups of the next (smaller) term of the original chain. Later it will enable us, subject to certain conditions, to make numerically trivial classes anisotropic.

Statement 6.8. Let $n \in \mathbb{N}$ and $X_r \xrightarrow{j_r} X_{r-1} \xrightarrow{j_{r-1}} \ldots \xrightarrow{j_2} X_1 \xrightarrow{j_1} X_0$ be embeddings of codimension 1 of irreducible subvarieties, smooth outside $n$-anisotropic closed subschemes, with $X_r$ not $n$-anisotropic. Then, over some f.g. purely transcendental extension of $k$, it can be complemented to a commutative diagram

$$
\begin{array}{ccc}
X'_r & \xrightarrow{j'_r} & X'_{r-1} \\
\Downarrow g_r & & \Downarrow g_{r-1} \\
X_r & \xrightarrow{j_r} & X_{r-1}
\end{array}
\quad
\begin{array}{ccc}
X'_{r-2} & \xrightarrow{j'_{r-2}} & \ldots \\
\Downarrow g_{r-2} & & \\
X_{r-2} & \xrightarrow{j_{r-2}} & \ldots
\end{array}
\quad
\begin{array}{ccc}
\ldots & \xrightarrow{j'_2} & X'_1 \\
\Downarrow g_2 & & \\
\ldots & \xrightarrow{j_2} & X_1
\end{array}
\quad
\begin{array}{c}
\Downarrow j'_1 \\
\Downarrow j_1 \\
X_0
\end{array}
$$

where all maps are embeddings of codimension 1 of irreducible subvarieties, smooth outside $n$-anisotropic closed subschemes and for any $i$, the map

$$(j'_i)^* \cdot (g_{i+1})_* : \text{Ch}^*_k(X'_i) \oplus \text{Ch}^*_{k/k}(X_{i+1}) \to \text{Ch}^*_k(X'_i)$$

is surjective (for $i = r$, the map $(j'_r)^*$ is surjective), and $|X'_{i+1}| = |X_{i+1}| \in \text{Ch}^1_{k/k}(X'_i)$.

Proof. This follows from the inductive application of Statement 6.7 from top to bottom. Finally, in the last step, we take $X'_r$ to be the closure of the generic representative of the respective (very ample) linear system $|X_r + n \cdot D|$ without any base set. Because $X_r$ is not $n$-anisotropic, $X'_r$ is nonempty and irreducible. By Statement 6.3, we have a surjection $(j'_r)^* : \text{Ch}^*_k(X'_{r-1}) \to \text{Ch}^*_k(X'_r)$.

Note that although $X'_{r-1}$ is still not $n$-anisotropic, $X'_r$ may be, in principle, anisotropic.

We also have a ‘smooth’ version of the above result, which is what we will use below.
Statement 6.9. Let $X_0$ be a smooth projective connected variety and $X_r \xrightarrow{j_r} X_{r-1} \xrightarrow{j_{r-1}} \ldots \xrightarrow{j_2} X_1 \xrightarrow{j_1} X_0$ be regular embeddings of codimension 1 of connected varieties, with $X_r$ not $n$-anisotropic. Then, over some f.g. purely transcendental extension of $k$, it can be complemented to a commutative diagram

\[
\begin{array}{ccccccc}
X'_r & \xrightarrow{j'_r} & X'_{r-1} & \xrightarrow{j'_{r-1}} & X'_{r-2} & \xrightarrow{j'_{r-2}} & \ldots & \xrightarrow{j'_{r-2}} & X_1 & \xrightarrow{j_1} & X_0' \\
\downarrow{g_r} & & \downarrow{g_{r-1}} & & \downarrow{g_{r-2}} & & \ldots & & \downarrow{g_1} & & \\
\tilde{X}'_r & \xrightarrow{j_r} & \tilde{X}'_{r-1} & \xrightarrow{j_{r-1}} & \tilde{X}'_{r-2} & \xrightarrow{j_{r-2}} & \ldots & \xrightarrow{j_{r-2}} & \tilde{X}_1 & \xrightarrow{\pi_1} & X_0
\end{array}
\]

where the upper and lower horizontal maps are regular embeddings of codimension 1 of connected varieties, and the vertical ones are blow-ups in $n$-anisotropic centers. In particular, the maps $\pi_i^*: \text{Ch}^*_k(X_i) \rightarrow \text{Ch}^*_k(\tilde{X}_i)$ are isomorphisms. In addition, for any $i$, the map

\[
((j_i')^*, (g_{i+1})_*\pi_i^*) : \text{Ch}^*_k(X_{i-1}) \oplus \text{Ch}^{*-1}_k(X_{i+1}) \rightarrow \text{Ch}^*_k(X_i)
\]

is surjective (for $i = r$, the map $(j_r')^*$ is surjective), and $[X_{i+1}] = (g_{i+1})_*[\tilde{X}_{i+1}] \in \text{Ch}^1_k(X_i)$.

Proof. By Statement 6.8, we get the commutative diagram

\[
\begin{array}{ccccccc}
\overline{X}_r & \xrightarrow{j_r} & \overline{X}_{r-1} & \xrightarrow{j_{r-1}} & \overline{X}_{r-2} & \xrightarrow{j_{r-2}} & \ldots & \xrightarrow{j_{r-2}} & \overline{X}_1 & \xrightarrow{j_1} & X_0 \\
\downarrow{\overline{g}_r} & & \downarrow{\overline{g}_{r-1}} & & \downarrow{\overline{g}_{r-2}} & & \ldots & & \downarrow{\overline{g}_2} & & \\
X_r & \xrightarrow{j_r} & X_{r-1} & \xrightarrow{j_{r-1}} & X_{r-2} & \xrightarrow{j_{r-2}} & \ldots & \xrightarrow{j_{r-2}} & X_1 & \xrightarrow{j_1} & X_0
\end{array}
\]

where $\overline{X}_i$ are irreducible varieties smooth outside some closed proper $n$-anisotropic subschemes, the maps

\[
((\overline{j}_i)^*, (\overline{g}_{i+1})_*): \text{Ch}^*_k(\overline{X}_{i-1}) \oplus \text{Ch}^{*-1}_k(X_{i+1}) \rightarrow \text{Ch}^*_k(\overline{X}_i)
\]

are surjective, and $[\overline{X}_{i+1}] = [X_{i+1}] \in \text{Ch}^1(\overline{X}_i)$.

Let $\pi_0: X'_0 \rightarrow X_0$ be the embedded desingularization of $\overline{X}_r \subset \overline{X}_{r-1} \subset \overline{X}_{r-2} \subset \ldots \subset \overline{X}_1 \subset \overline{X}_0$ and $\varepsilon_i : X'_i \rightarrow \overline{X}_i$ be the proper pre-images (with $\varepsilon_0 = \pi_0$). Because special divisors are $n$-anisotropic, we have isomorphisms $\varepsilon_i^*: \text{Ch}^*_k(\overline{X}_i) \rightarrow \text{Ch}^*_k(\tilde{X}_i)$, noting that $X_i$ is not $n$-anisotropic, by blowing $X_i$ at $n$-anisotropic centers, we may resolve the indeterminacies of the maps $X_i \xrightarrow{\varepsilon_i} \overline{X}_{i-1} \rightarrow X'_i$ and $X_i \xrightarrow{j_i} X_{i-1} \rightarrow \tilde{X}_{i-1}$ and obtain...
Let us denote the original sequence as \( X_r \xrightarrow{j_r} X_{r-1} \xrightarrow{j_{r-1}} \ldots \xrightarrow{j_2} X_1 \xrightarrow{j_1} X_0 \) be regular embeddings of codimension 1 of smooth connected varieties. Then over some f.g. purely transcendental extension there exists a blow-up in \( n\)-anisotropic centers \( \hat{X}_0 \to X_0 \) and a similar sequence of embeddings \( \hat{X}_r \xrightarrow{j_r} \hat{X}_{r-1} \xrightarrow{j_{r-1}} \ldots \xrightarrow{j_2} \hat{X}_1 \xrightarrow{j_1} \hat{X}_0 \), where \( \hat{X}_r = [X_r] \in \Ch^*_k(X_0) \) and the image of the restriction \( f_j^*: \Ch^*_k(\hat{X}_j) \to \Ch^*_k(X_r) \) as a \( \Ch^*_k(X_0) \)-module is generated by monomials \( \hat{c}^j = \prod_{i=2}^j c_1^{l_i}(\hat{N}_i) \), for \( j\)-good \( \hat{l} \), where \( \hat{N}_i = N_{\hat{X}_i \subset \hat{X}_{i-1}} \), and the image of the map \( f_0)_s f_j^*: \Ch^*_k(\hat{X}_j) \to \Ch^{n+r}_k(\hat{X}_0) \) as a \( \Ch^*_k(X_0) \)-module is generated by elements \( \hat{c}^0 \cdot [X_r] = \prod_{i=2}^r c_1^{l_i}(N_i) \cdot [X_r] \), where \( N_i = N_{X_i \subset X_{i-1}} \) and \( \hat{l} \) runs over all \( j\)-good vectors (here \( f_i: \hat{X}_i \to \hat{X}_{i-1} \) is the embedding). In particular, the image of \( (f_0)_s: \Ch^*_k(\hat{X}_r) \to \Ch^{n+r}_k(\hat{X}_0) \) as a \( \Ch^*_k(X_0) \)-module is generated by elements \( \hat{c}^0 \cdot [X_r] \), where \( \hat{l} \) runs through all vectors.

**Proof.** Let us denote the original sequence as \( X_r^0 \xrightarrow{j_r^0} X_{r-1}^0 \xrightarrow{j_{r-1}^0} \ldots \xrightarrow{j_2^0} X_1^0 \xrightarrow{j_1^0} X_0^0 \). Either \( X_r^0 \) is \( n\)-anisotropic, in which case there is nothing to prove, or we can produce a diagram as in Statement 6.9. We can iterate this process as long as the variety \( X_r^m \) is not \( n\)-anisotropic and obtain diagrams.
These induce maps on isotropic Chow groups:

\[
\begin{align*}
\text{Ch}^*_{k/k}(X_{i+1}^{m+1}) &\xrightarrow{\alpha_{m+1}^i} \text{Ch}^*_{k/k}(X_i^{m+1}) \xrightarrow{\alpha_{m}^i} \cdots \xrightarrow{\alpha_{1}^i} \text{Ch}^*_{k/k}(X_1^{m+1}) \xrightarrow{\alpha_{0}^i} \text{Ch}^*_{k/k}(X_0^{m+1}) \\
\beta_{m+1} &\xrightarrow{[1]} \text{Ch}^*_{k/k}(X_i^{m+1}) \xrightarrow{[1]} \cdots \xrightarrow{[1]} \text{Ch}^*_{k/k}(X_1^{m+1}) \xrightarrow{[1]} \text{Ch}^*_{k/k}(X_0^{m+1})
\end{align*}
\]

where \(\alpha_i^i = (q_i^i)^*\), \(\beta_i^i = (g_i^i)^*(\pi_i^{i-1})^*\) and \(\beta\)-maps shift the codimension by \((+1)\). The maps

\[
(\alpha_i^l, \beta_{i+1}^l) : \text{Ch}^*_{k/k}(X_{i-1}^l) \oplus \text{Ch}^*_{k/k}(X_{i-1}^{l-1}) \rightarrow \text{Ch}^*_{k/k}(X_i^l)
\]

are surjective. Either at some stage we will get an \(n\)-anisotropic \(X_m^i\), in which case we are done, or we can iterate the process \(q = \dim(X) + 1\) times. Set \(\hat{X}_i = X_i^q\), etc. Then \(\text{Ch}^*_{k/k}(\hat{X}_i)\) is generated by the elements of the form \(\omega(x)\), where \(\omega\) is a composition of \(\alpha\)s and \(\beta\)s and \(x \in \text{Ch}^*_{k/k}(X_0)\). Here we are using the fact that the number of \(\beta\)s in such a composition cannot be more than \(\dim(X_i)\) (because each \(\beta\) increases the codimension by \(1\)), so the chain has to start with \(X_0\). We also have maps \(\gamma_i^l = (j_i^l)^*\) and \(\delta_i^l = (\pi_i^{i-1})^*(g_i^l)^*\) fitting commutative diagrams (recall that \((\pi_i^m)^*\) and \((\pi_i^m)^*\) are isomorphisms)

\[
\begin{align*}
\text{Ch}^*_{k/k}(X_i^{m+1}) &\xrightarrow{\gamma_{m+1}^i} \text{Ch}^*_{k/k}(X_i^{m+1}) \quad \text{and} \quad \text{Ch}^*_{k/k}(X_i^{m+1}) &\xleftarrow{\alpha_{m+1}^i} \text{Ch}^*_{k/k}(X_i^{m+1}) \\
\beta_{m+1} &\xrightarrow{[1]} \text{Ch}^*_{k/k}(X_i^{m+1}) \xrightarrow{[1]} \cdots \xrightarrow{[1]} \text{Ch}^*_{k/k}(X_i^{m+1}) \xrightarrow{[1]} \text{Ch}^*_{k/k}(X_i^{m+1})
\end{align*}
\]

Note that

\[
\begin{align*}
\beta_{m+1}^i \delta_{i+1}^{m+1}(u) &= u \cdot c_1(N_{\hat{X}_i^m \to X_i^{m+1}}) = u \cdot c_1(N_{X_i^{m+1} \subset X_i^{m+1}}) = \gamma_{m+1}^i \alpha_{m+1}^i(u) \quad \text{and} \\
\delta_{i+1}^{m+1} \beta_{m+1}^i(v) &= v \cdot c_1(N_{\hat{X}_i^m \to X_i^{m+1}}) = v \cdot c_1(N_{X_i^{m} \subset X_i^{m+1}}) = \alpha_{m+1}^i \gamma_{m+1}^i(v).
\end{align*}
\]

Using these relations, one can reduce \(\omega(x)\) to the form \(\theta(x)\), where \(\theta\) is a combination of \(\alpha_i^q\)s and \(\gamma_i^q\)s. The restriction of such an element to \(\text{Ch}^*_{k/k}(X_i^q)\) is \(f_j^*(x)\) times a monomial in \(c_1(N_{X_i^q \subset X_i^{q-1}}) = c_1(\hat{N}_i)\), where each factor \(c_1(\hat{N}_i)\) corresponds to a loop \(\alpha_i^q \gamma_i^q\) in \(\theta\). Thus, the image \(f_j^* : \text{Ch}^*_{k/k}(\hat{X}_j) \rightarrow \text{Ch}^*_{k/k}(\hat{X}_r)\) as a \(\text{Ch}^*_{k/k}(X_0)\)-module is generated by monomials in \(c_1(\hat{N}_i)\)s. Because such a monomial corresponds to a closed path from \(X_j^q\) to itself, these will be exactly \(j\)-good monomials. In addition, we need to observe that
\( c_1(\hat{N}_i) = c_1(N_{\hat{X}_i \subset \hat{X}_0}) \) is the restriction of a class from \( \hat{X}_0 \). Finally, from the same relations, we get that \((f_0)_*c^n = \gamma_1^q \ldots \gamma_r^q e^{\tilde{n}} = \gamma_1^0 \ldots \gamma_r^0 e^{\tilde{n}} = c^{\tilde{n}} \cdot [X_r]\). Hence, the image of \((f_0)_*(f_j)^*: \text{Ch}^{\bullet}_{k/k}(\hat{X}_j) \rightarrow \text{Ch}^{\bullet+r}_{k/k}(X_0)\) as a \( \text{Ch}^{\bullet}_{k/k}(X_0)\)-module is generated by elements \( c^{\bar{j}} \cdot [X_r] \), where \( \bar{j} \) runs over all \( j \)-good vectors.

With the previous result in hand we have a practical tool ensuring the anisotropy of Chow group elements.

**Corollary 6.11.** Let \( X_r \xrightarrow{j_r} X_{r-1} \xrightarrow{j_{r-1}} \ldots \xrightarrow{j_2} X_1 \xrightarrow{j_1} X_0 \) be regular embeddings of codimension 1 of smooth connected varieties with \( N_i = N_{X_i \subset X_{i-1}} \). Suppose that \( c^{\bar{j}} \cdot [X_i] \overset{\text{Num}}{\sim} 0 \) on \( X_0 \), for all monomials in \( c_1(N_i)s \), \( i \geq 2 \). Then, over some f.g. purely transcendental extension, \( [X_r] = 0 \in \text{Ch}^r_{k/k}(X_0) \).

**Proof.** By Statement 6.10, over some f.g. purely transcendental extension of \( k \), there exists a blow-up with \( n \)-anisotropic centers \( \pi : \hat{X} \rightarrow X \) and a sequence \( \hat{X}_r \xrightarrow{j_r} \hat{X}_{r-1} \xrightarrow{j_{r-1}} \ldots \xrightarrow{j_2} \hat{X}_1 \xrightarrow{j_1} \hat{X}_0 \) of regular embeddings of smooth connected projective varieties, such that \( [\hat{X}_r] = [X_r] \in \text{Ch}^r_{k/k}(\hat{X}_0) = \text{Ch}^r_{k/k}(X_0) \) and the image of the map \((f_0)_*: \text{Ch}^r_{k/k}(\hat{X}_r) \rightarrow \text{Ch}^r_{k/k}(\hat{X}_0)\) as a module over \( \text{Ch}^r_{k/k}(X_0)\) is generated by \( c^{\bar{j}} \cdot [X_r] \), for all \( r \)-good (=all) \( \bar{j} \), where \( f_0 : \hat{X}_r \rightarrow \hat{X}_0 \). Because all of these classes are \( \overset{\text{Num}}{\sim} 0 \) on \( \hat{X}_0 \), the zero-dimensional component of our image is zero. This means that \( \hat{X}_r \) is anisotropic and so \( [\hat{X}_r] = 0 \in \text{Ch}^r_{k/k}(\hat{X}_0) \).

In the case \( r = 2 \), we get the following.

**Corollary 6.12.** Let \( S \subset X \) be a regular embedding of codimension 2 of smooth connected projective varieties. Suppose that \( c_1^m(N_{S \subset X}) \cdot [S] \overset{\text{Num}}{\sim} 0 \) on \( X \), for any \( m \geq 0 \). Then, over some f.g. purely transcendental extension, \( [S] = 0 \in \text{Ch}^2_{k/k}(X) \).

**Proof.** By blowing \( X \) at \( S \) we may assume that \( S \) is contained in a smooth connected divisor \( Z \). Note that the ‘new’ characteristic classes of \( S \) are pull-backs of the ‘old’ ones and so are numerically trivial as well. We obtain the triple \( S \rightarrow Z \rightarrow X \). Our statement now is a particular case of Corollary 6.11, where it remains to observe that \( c_1(N_{S \subset X}) = c_1(N_{S \subset Z}) + c_1(N_{Z \subset X}) \), where the second summand is defined on \( X \).

**Acknowledgement.** I am very grateful to J.-L. Colliot-Thélène for useful discussions, to C. Voisin for helpful comments and drawing my attention to [13, Theorem 5] and to J. I. Kylling, P. A. Østvær, O. Röndigs and S. Yagunov for fruitful interaction during my visit to the University of Oslo, which led to the inclusion of Section 5. In addition, I am very grateful to T. Bachmann for the valuable remarks on a previous version of the article. Finally, I thank the referee for many useful suggestions that helped to improve the exposition.
