On distance distribution functions-valued submeasures related to aggregation functions

Lenka HALČINOVÁ, Ondrej HUTNÍK and Radko MESIAR

Abstract. Probabilistic submeasures generalizing the classical (numerical) submeasures are introduced and discussed in connection with some classes of aggregation functions. A special attention is paid to triangular norm-based probabilistic submeasures and semi-copula-based probabilistic submeasures. Some algebraic properties of classes of such submeasures are also studied.

1 Introduction and motivations

In recent years non-additive set functions have attracted much attention in pure mathematics as well as in various applications. This class includes well-known set functions such as submeasures, Dobrakov submeasures and semi-measures, fuzzy measures, null additive set functions, etc. As a larger overview of non-additive set functions we recommend monographs [18] and [20], or several chapters in the handbook [17].

The study of submeasures was initiated in the second half of the last century by Orlicz and developed by Drewnowski [3] from the topological point of view. In fact, many classical objects of measure theory, as e.g. variations and semi-variations of vector measures, are submeasures. This classical object of measure theory is defined as follows. Let \( \Sigma \) be a ring of subsets of a fixed (non-empty) set \( \Omega \) and \( \mathbb{R}_+ = [0, +\infty] \) be the extended non-negative real half-line. A mapping \( \eta : \Sigma \to \mathbb{R}_+ \) satisfying the conditions

(i) \( \eta(\emptyset) = 0; \)

(ii) \( \eta(E) \leq \eta(F) \) for \( E, F \in \Sigma \) such that \( E \subset F; \)

(iii) \( \eta(E \cup F) \leq \eta(E) + \eta(F) \) whenever \( E, F \in \Sigma. \)

is said to be a numerical submeasure on \( \Sigma. \)

In our previous papers [12] and [11] we have introduced and investigated submeasure notions related to probabilistic metric spaces (PM-spaces, for short), see [16]. Our considerations of a submeasure notion in paper [12] were closely related to the Menger PM-space \( (\Omega, \mathcal{F}, \tau_T) \) where \( \tau_T \) is the triangle function in the form

\[
\tau_T(G, H)(x) = \sup_{u + v = x} T(G(u), H(v))
\]

with \( T \) being a left-continuous t-norm. The associated submeasure notion was defined as follows, see [12] Definition 3] and Section 2 for necessary notations.

1 Mathematics Subject Classification (2010): Primary 60A10

Key words and phrases: submeasure, distribution function, probabilistic metric space, triangular norm, aggregation function, semi-copula, lattice
Definition 1.1 Let $T : [0, 1]^2 \rightarrow [0, 1]$ be a t-norm, and $\Sigma$ a ring of subsets of $\Omega \neq \emptyset$. A mapping $\gamma : \Sigma \rightarrow \Delta^+$ (where $\gamma(E)$ is denoted by $\gamma_E$) such that

(a) if $E = \emptyset$, then $\gamma_E(x) = \varepsilon_0(x)$, $x > 0$;
(b) if $E \subset F$, then $\gamma_E(x) \geq \gamma_F(x)$, $x > 0$;
(c) $\gamma_{E \cup F}(x + y) \geq T(\gamma_E(x), \gamma_F(y))$, $x, y > 0$, $E, F \in \Sigma$,

is said to be a $\tau_T$-submeasure.

From this definition is obvious that the probabilistic submeasure is a certain (non-additive) set function taking values in the set of distribution functions of non-negative random variables. The attribute "submeasure" reflects the property (c) which is a "probabilistic" version of the classical subadditivity. The origin of this notion comes from the fact that it works in such situations in which we have only a probabilistic information about measure of a set (recall a similar situation in the framework of information measures). For example, if rounding of reals is considered, then the uniform distributions over intervals describe our information about the measure of a set.

On the other hand, $\tau_T$-submeasures can be seen as fuzzy number-valued submeasures. In this case the value $\gamma_E$ can be seen as a non-negative $LT$-fuzzy number, see [4], where $\tau_T(\gamma_E, \gamma_F)$ corresponds to the $T$-sum of fuzzy numbers $\gamma_E$ and $\gamma_F$. Moreover, each $\tau_T$-submeasure $\gamma$ with the minimum t-norm $T = M$ (in [12] we call it universal $\tau_T$-submeasure) can be represented by means of a non-decreasing system $(\eta_\alpha)_{\alpha \in [0, 1]}$ of numerical submeasures (compare the horizontal representation $(S_\alpha)_{\alpha \in [0, 1]}$ of a fuzzy subset $S$), where

$$\gamma_E(x) = \sup\{\alpha \in [0, 1]; \eta_\alpha(E) \leq x\}, \quad E \in \Sigma.$$

Example 1.2 Let $\eta$ be a numerical submeasure on $\Sigma$. Then for each $E \in \Sigma$ the mapping

$$\gamma_E(x) = 1 - \exp\left(-\left[\frac{x}{\lambda \eta(E)}\right]^k\right), \quad x > 0, \lambda > 0, k > 0,$$

corresponds to a cumulative distribution function of the Weibull distribution $W(\lambda, k)$ with parameters $\lambda, k$. Especially, for $k = 1$ we get the (universal) $\tau_T$-submeasure corresponding to a distribution function of exponential distribution $E(\lambda)$ with parameter $\lambda$. Note that the standard conventions for the arithmetic operations on $\mathbb{R}^+$ are considered, such as $0 \cdot (+\infty) = 0 / 0 = 0$.

Naturally, we may ask about possibility to extend our considerations from Menger PM-spaces to wider spaces with different triangular functions instead of $[1]$. Note that similar considerations were introduced and discussed in the framework of probabilistic metric spaces, see for example the monograph [8]. For such reasons in paper [11] we have provided a generalization of $\tau_T$-submeasures which involves suitable operations $L$ replacing the standard addition $+$ on $\mathbb{R}^+$ such that the underlying function $[1]$ is a triangle function and thus the underlying space is the so-called $L$-Menger PM-space. Since t-norms are rather special operations on the unit interval $[0, 1]$, we have also mentioned few possible generalizations of a submeasure notion based on aggregation operators.
and convolution of distance distribution functions, i.e., such submeasures which
can be used in non-Menger PM-spaces (e.g., in the Wald spaces), but also in
wider class of PM-spaces.

The aim of this paper is a further generalization of the concept of probabilis-
tic submeasures. In particular, triangular norms applied in (c) of Definition 1.1
are used as binary functions only, and thus their associativity is a superfluous
constraint. Therefore, a more general aggregation function can be used here
(compare, e.g., the case of fuzzy logics, where the triangular norms can be re-
placed by (quasi-)copulas as discussed in [10]).

The paper is organized as follows: in Section 2 we recall some basic and
necessary notions which will be used in this paper. Then in Section 3 we in-
vestigate further properties of triangular norm-based probabilistic submeasures
which generalize some results obtained in our previous papers. Passing from
triangular norms to their natural extension/modification in the form of copulas,
quasi-copulas and semi-copulas we study in Section 4 notion of submeasures re-
lated to these aggregation functions. In the whole paper a number of examples is
presented. The lattice structure of spaces of semi-copula and quasi-copula-based
submeasures is also discussed.

2 Basic notions and definitions

The class of all distance distribution functions (distribution functions of non-
negative random variables) will be denoted by \( \Delta^+ \). A triangle function is a
function \( \tau : \Delta^+ \times \Delta^+ \rightarrow \Delta^+ \) which is symmetric, associative, non-decreasing in
each variable and has \( \varepsilon_0 \) as the identity, where \( \varepsilon_0 \) is the distribution function of
Dirac random variable concentrated in point 0. More precisely, for \( a \in [0, +\infty[ \)
we put

\[
\varepsilon_a(x) = \begin{cases} 
1 & \text{for } x > a, \\
0 & \text{otherwise.}
\end{cases}
\]

Clearly, \( (\Delta^+, \tau) \) is an Abelian semigroup with the identity \( \varepsilon_0 \). A triangular
norm, shortly a t-norm, is a commutative lattice ordered semi-group on \([0,1]\)
with identity 1. The most important t-norms are the minimum \( M(x, y) = \min\{x, y\} \), the product \( \Pi(x, y) = xy \), the Lukasiewicz \( W(x, y) = \max\{x + y - 1, 0\} \) and the drastic product

\[
D(x, y) = \begin{cases} 
\min\{x, y\} & \text{for } \max\{x, y\} = 1 \\
0 & \text{otherwise.}
\end{cases}
\]

For more information about t-norms we refer the book [13]. We denote by \( \mathcal{T} \)
the class of all t-norms.

Triangular norms are a rather special case of aggregation functions on \([0, 1]\).
A binary aggregation function \( A : [0,1]^2 \rightarrow [0,1] \) is a non-decreasing function
in both components with the boundary conditions \( A(0,0) = 0 \) and \( A(1,1) = 1 \).
The class of all binary aggregation functions will be denoted by \( \mathcal{A} \). For more
details on aggregation functions we recommend a recent monograph [9].

Let us denote by \( \mathcal{L} \) the set of binary operations on \( \mathbb{R}_+ \), such that

(i) \( \mathcal{L} \) is commutative and associative;
(ii) $L$ is jointly strictly increasing, i.e., for all $u_1, u_2, v_1, v_2 \in \mathbb{R}_+$ with $u_1 < u_2, v_1 < v_2$ holds $L(u_1, v_1) < L(u_2, v_2)$;

(iii) $L$ is continuous on $\mathbb{R}_+ \times \mathbb{R}_+$;

(iv) $L$ has 0 as its neutral element.

Observe that $L \in \mathcal{L}$ is a jointly increasing pseudo-addition on $\mathbb{R}_+$ in the sense of [19]. The usual examples of operations in $\mathcal{L}$ are

$$K_\alpha(x, y) = (x^\alpha + y^\alpha)^{\frac{1}{\alpha}}, \quad \alpha > 0,$$

$$K_{\infty}(x, y) = \max\{x, y\}.$$  

Note that although $\max\{x, y\} \in \mathcal{L}$, its "counterpart" $\min\{x, y\}$ is not a member of $\mathcal{L}$, because $\min\{x, y\}$ does not have 0 as its neutral element. With $(L, A) \in \mathcal{L} \times \mathcal{A}$ the general form of (1) is as follows

$$\tau_{L,A}(G, H)(x) = \sup_{L(u,v)=x} A(G(u), H(v)).$$

Note that the left-continuity of $A$ ensures that $\tau_{L,A}$ is a binary operation on $\Delta^+$. However, $\tau_{L,A}$ need not be associative in general, but it has good properties on $\Delta^+$.

Now we introduce the following probabilistic submeasure notion in its general form (note that neither the left-continuity of a t-norm $T$ nor of an aggregation function $A$ is required in what follows).

**Definition 2.1** Let $(L, A) \in \mathcal{L} \times \mathcal{A}$ and $\Sigma$ be a ring of subsets of $\Omega \neq \emptyset$. A mapping $\gamma : \Sigma \rightarrow \Delta^+$ such that

(a') $\gamma_E(x) = \varepsilon_0(x), \ x > 0$;

(b') $\gamma_E(x) \geq \gamma_F(x), \ x > 0$ whenever $E \subset F$;

(c') $\gamma_{E \cup F}(L(x, y)) \geq A(\gamma_E(x), \gamma_F(y)), \ x, y > 0, \ E, F \in \Sigma$,

is said to be a $\tau_{L,A}$-submeasure.

If $L = K_1$, then its index is usually omitted, and we simply speak about $\tau_A$-submeasure. Clearly, for $A = T$ (a left-continuous t-norm), and $L = K_1$ the $\tau_{L,A}$-submeasure reduces to $\tau_T$-submeasure from [12]. For instance, for $L = K_\infty$ we get a $\tau_{\max,T}$-submeasure related to a non-Archimedean Menger PM-space $(\Omega, \mathcal{F}, \tau_{\max,T})$. It is worth to note that in this case condition (c') reads as follows

$$\gamma_{E \cup F}(s) \geq T(\gamma_E(s), \gamma_F(s)), \ s > 0, E, F \in \Sigma.$$  

**Remark 2.2** In general, $L \in \mathcal{L}$ if and only if there is a (possibly empty) system $(a_k, b_k)_{k \in K}$ of pairwise disjoint open subintervals of $[0, +\infty[$, and a system $(\ell_k)_{k \in K}$ of increasing bijections $\ell_k : [a_k, b_k] \rightarrow \mathbb{R}_+$ so that

$$L(x, y) = \begin{cases} \ell_k^{-1}(\ell_k(x) + \ell_k(y)) & \text{if } (x, y) \in ]a_k, b_k[^2, \\ \max\{x, y\} & \text{otherwise.} \end{cases}$$  

4
For more details see [13]. For \( L = K_a \in \mathcal{L} \) and \( A = T \in \mathcal{T} \) we have
\[
\tau_{K_a, T}(G, H)(x) = \tau_T(G, H)(\ell(x)),
\]
which motivates us to say that for \( L \in \mathcal{L} \) generated by a strictly increasing bijection \( \ell: \mathbb{R}_+ \to \mathbb{R}_+ \), we denote \( L = K_\ell \), we have
\[
\tau_{K_\ell, T}(G, H)(x) = \tau_T(G, H)(\ell(x)).
\]
In this light we have
\[
\gamma_{E \cup F}(L(x, y)) = \gamma_{F \cup E}(L(y, x)) \geq \max\{A(\gamma_E(x), \gamma_F(y)), A(\gamma_F(y), \gamma_E(x))\},
\]
for \( x, y > 0, E, F \in \Sigma \). So, we may (equivalently) take the symmetrization
\[
A_{\text{sym}}(u, v) = \max\{A(u, v), A(v, u)\}
\]
instead of \( A \in \mathcal{A} \).

Easily, by standard methods of measure theory it is possible to extend a \( \tau_{L,A} \)-submeasure \( \gamma \) from a ring \( \Sigma \subset \mathcal{P}(\Omega) \) of subsets of \( \Omega \neq \emptyset \) to a set function \( \gamma^*: \mathcal{P}(\Omega) \to \Delta^+ \) as follows
\[
\gamma^*_E(x) = \sup\{\gamma_F(x); E \subseteq F \in \Sigma\}, \quad x > 0, E \in \Omega.
\]

**Problem 1** Fix \((L, A) \in \mathcal{L} \times \mathcal{A} \) and let \( \gamma \) be a \( \tau_{L,A} \)-submeasure on a ring \( \Sigma \) of subsets of \( \Omega \neq \emptyset \). Is the (Jordan) extension \( \gamma^* \) of \( \gamma \) also a \( \tau_{L,A} \)-submeasure on \( \mathcal{P}(\Omega) \)?

For better readability in what follows we use the following convention: since \( \Delta^+ \) is the set of all distribution functions with support \( \mathbb{R}_+ \), we state the expression for a \( \tau_{L,A} \)-submeasure \( \gamma: \Sigma \to \Delta^+ \) with \((L, A) \in \mathcal{L} \times \mathcal{A} \) just for positive values of \( x \). Usually we also omit the information "for \( x > 0^+ \) if it is not necessary and in accordance with our convention. In case \( x \leq 0 \) we always suppose \( \gamma(x) = 0 \).

Furthermore, in the whole paper \( \Theta_{L,A} \) denotes the set of all \( \tau_{L,A} \)-submeasures on \( \Sigma \) for a fixed \((L, A) \in \mathcal{L} \times \mathcal{A} \) and
\[
\Theta_{\mathcal{L},\mathcal{A}} = \{\Theta_{L,A}; (L, A) \in \mathcal{L} \times \mathcal{A}\}
\]
the set of all \( \tau_{L,A} \)-submeasures on \( \Sigma \) for all possible pairs \((L, A) \in \mathcal{L} \times \mathcal{A} \) (or, the "superset" of all sets of \( \tau_{L,A} \)-submeasures on \( \Sigma \)). Here also, as a convention, we omit the index \( L = K_1 \) and write \( \Theta_A \) instead of \( \Theta_{K_1,A} \).

**Example 2.3** For the set \( \Omega = \{\omega_1, \omega_2\} \) and positive constants \( a, b, c \) such that \( c \leq \min\{a, b\} \), put
\[
\gamma_{\omega_1}(x) = \max\{0, 1 - e^{-ax}\},
\gamma_{\omega_2}(x) = \max\{0, 1 - e^{-bx}\},
\gamma_\Omega(x) = \max\{0, 1 - e^{-cx}\}.
\]
Then \( \gamma \in \Theta_A, A \in \mathcal{A} \), if and only if
\[
A(u, v) \leq (1 - u)^\# \cdot (1 - v)^\#.
\]
Hence, for \( a = b = \frac{2}{3}c \), we have \( \gamma \in \Theta_\Omega \), but \( \gamma \notin \Theta_M \). Observe also that \( \gamma \) is not related to any numerical submeasure, see [12].
Example 2.4 For a positive real number $p$ consider the class $\mathcal{M}_p \subset \mathcal{A}$ which is usually called the $p$-mean (or, the Hölder mean) and is defined as

$$M_p(x, y) = \left(\frac{x^p + y^p}{2}\right)^{1/p}, \quad x, y \geq 0.$$ 

If $\eta$ is a numerical submeasure on $\Sigma$, then $\gamma \in \Theta_{\mathcal{M}_p}$, where

$$\gamma_E(x) = 2^{-1/p} \left(1 + \max \left\{ \min \left\{ \sqrt[p]{\max \left\{ 1 + p(x - \eta(E)), 0 \right\}}, 1 \right\}, 0 \right\} \right)^{1/p}$$

and $E \in \Sigma$. Since $\lim_{p \to 0} M_p = G$, the geometric mean, then $\gamma \in \Theta_G$ has the form

$$\gamma_E(x) = \sqrt{\min \left\{ e^{x - \eta(E)}, 1 \right\}}, \quad E \in \Sigma.$$ 

Also, for $p = 1$, resp. $p = 2$, the $p$-mean is nothing but the arithmetic mean $A$, resp. the quadratic mean $Q$, and therefore we easily get the corresponding $\tau_{A^{-}}$, resp. $\tau_{Q^{-}}$-submeasure.

3 Triangular norm-based submeasures

In what follows we use the usual point-wise order $\leq$ between real-valued functions. Since $\gamma \in \Delta^+$ is non-decreasing, then for a fixed $T \in \mathcal{T}$ each $\tau_{L,T}$-submeasure is a $\tau_{L_2,T}$-submeasure whenever $L_1 \leq L_2$. Moreover, if $T_2 \leq T_1$ (it is usually said that $T_2$ is a weaker t-norm than $T_1$, or $T_1$ is stronger than $T_2$, see [13]), then each $\tau_{L_1,T_1}$-submeasure is a $\tau_{L_2,T_2}$-submeasure. In accordance with this motivation introduce the order $\ll$ on $\Theta_{\mathcal{L},\mathcal{T}}$ as follows

$$\Theta_{L_1,T_1} \ll \Theta_{L_2,T_2} \quad \text{if and only if} \quad L_1 \leq L_2 \text{ and } T_2 \leq T_1.$$ 

Then $(\Theta_{\mathcal{L},\mathcal{T}}, \ll)$ is a partially ordered set and for each $(L,T) \in \mathcal{L} \times \mathcal{T}$ we have

$$\Theta_{L,M} \ll \Theta_{L,T} \ll \Theta_{L,D}.$$ 

Note that for $L = K_1$ the order $\ll$ on $\Theta_{\mathcal{T}}$ is nothing but order-inverted image of the point-wise order $\leq$ of t-norms.

Remark 3.1 Observe that the partial order $\ll$ is a coarsening of the standard inclusion ordering, i.e.,

$$\Theta_{L_1,T_1} \ll \Theta_{L_2,T_2} \quad \implies \quad \Theta_{L_1,T_1} \subset \Theta_{L_2,T_2}.$$ 

On the other hand, consider for example $L = K_\infty$. Then $\Theta_{K_\infty,T}$ does not depend on $T$ (in fact, it consists of probabilistic submeasures $\gamma$ satisfying $\gamma_E = \gamma_\Omega$ for any non-empty $E \subset \Omega$), although there are incomparable t-norms $T_1$ and $T_2$, i.e., $\Theta_{K_\infty,T_1}$ and $\Theta_{K_\infty,T_2}$ are $\ll$-incomparable.

Example 3.2 Let $\eta : \Sigma \to \mathbb{R}_+$ be a numerical submeasure on a ring $\Sigma$ of a non-empty set $\Omega$ and $E \in \Sigma$. Then
| Family of t-norms | Corresponding family of $\tau_T$-submeasures |
|-------------------|---------------------------------------------|
| **Aczél-Alsina t-norms**  
$T^A_A$, $\lambda \in [0, +\infty[$ | $\gamma^{AA,0}_E(x) = \varepsilon_{E^0}(x)$  
$\gamma^{AA,\lambda}_E(x) = \exp \left( - \left[ \max \{ \eta(E) - x, 0 \} \right]^{1/\lambda} \right)$ |
| **Dombi t-norms**  
$T^D_A$, $\lambda \in [0, +\infty[$ | $\gamma^{D,0}_E(x) = \gamma^{AA,0}_E(x)$  
$\gamma^{D,\lambda}_E(x) = \left( 1 + \left[ \max \{ \eta(E) - x, 0 \} \right]^{1/\lambda} \right)^{-1}$ |
| **Frank t-norms**  
$T^F_A$, $\lambda \in [0, +\infty[$ | $\gamma^{F,1}_E(x) = \min \left\{ \exp(x - \eta(E)), 1 \right\}$  
$\gamma^{F,+\infty}_E(x) = \max \left\{ \min \{1 + x - \eta(E), 1\}, 0 \right\}$  
$\gamma^{F,\lambda}_E(x) = \min \left\{ \log_\lambda \left( 1 + (\lambda - 1) \exp(x - \eta(E)) \right), 1 \right\}$ |
| **Hamacher t-norms**  
$T^H_A$, $\lambda \in [0, +\infty[$ | $\gamma^{H,+\infty}_E(x) = \gamma^{AA,0}_E(x)$  
$\gamma^{H,0}_E(x) = \min \left\{ (1 + \eta(E) - x)^{-1}, 1 \right\}$  
$\gamma^{H,\lambda}_E(x) = \min \left\{ \lambda \left( \exp(\eta(E) - x) + \lambda - 1 \right)^{-1}, 1 \right\}$ |
| **Yager t-norms**  
$T^Y_A$, $\lambda \in [0, +\infty[$ | $\gamma^{Y,0}_E(x) = \gamma^{AA,0}_E(x)$  
$\gamma^{Y,\lambda}_E(x) = \max \left\{ \min \left\{ 1 - \left[ \max \{ \eta(E) - x, 0 \} \right]^{1/\lambda}, 1 \right\}, 0 \right\}$ |
| **Sugeno-Weber t-norms**  
$T^{SW}_A$, $\lambda \in [-1, +\infty]$ | $\gamma^{SW,-1}_E(x) = \gamma^{AA,0}_E(x)$  
$\gamma^{SW,0}_E(x) = \gamma^{F,+\infty}_E(x)$  
$\gamma^{SW,+\infty}_E(x) = \gamma^{F,1}_E(x)$  
$\gamma^{SW,\lambda}_E(x) = \max \left\{ \min \left\{ \lambda^{-1} \left( (1 + \lambda)^{1+x-\eta(E)} - 1 \right), 1 \right\}, 0 \right\}$ |

Table 1: Some well known families of t-norms and their corresponding parameterized families of $\tau_T$-submeasures
(i) $\gamma \in \Theta_{L,M}$, where $L \in \mathcal{L}$, $L \geq K_1$ and
\[
\gamma_E(x) = \begin{cases} 
0 & \text{for } x \leq 0, \\
1/2 & \text{for } x \in [0, \eta(E)]; \\
1 & \text{for } x > \eta(E), 
\end{cases}
\]

(ii) $\gamma \in \Theta_{L,D}$, where $L \in \mathcal{L}$ is arbitrary and
\[
\gamma_E(x) = \frac{x}{x + \eta(E)};
\]

(iii) $\gamma \in \Theta_{L,W}$, where $L \in \mathcal{L}$, $L \geq K_1$ and
\[
\gamma_E(x) = \max \left\{ \min \{1 + x - \eta(E), 1\}, 0 \right\};
\]

(iv) for
\[
\gamma_E(x) = \min \left\{ \frac{1 + x}{1 + \eta(E)}, 1 \right\}, \quad x > 0,
\]
we have that $\gamma \in \Theta_D$, however it is not an element of $\Theta_W$, neither $\Theta_H$ nor $\Theta_M$.

More examples of $\tau$-submeasures related to some well known parameterized families of t-norms $T$, see [13], are summarized in Table 1. Note that in all cases we omit the minimum t-norm $M = T_{1/\infty}^{AA} = T_{3/\infty}^{D} = T_{0}^{F} = T_{SS}^{SS} = T_{Y}^{\infty}$ (one example of such a universal submeasure is given in (i)).

In the context of t-norms (but not limited to this case, as we will use later) it is very natural to consider the following simple transformations which often manifest in different applied fields. Consider the group $\mathcal{H}$ of automorphisms (strictly increasing bijections) of the unit interval $[0, 1]$ acting on the class $\mathcal{B}$ of all functions from $[0, 1]^2$ to $[0, 1]$ as follows
\[
(\Psi h B)(x, y) = h^{-1}(B(h(x), h(y))), \quad h \in \mathcal{H},
\]
for all $x, y \in [0, 1]$. We shall denote by $\Psi_{\mathcal{H}}$ this class of transformations (an element of $\Psi_{\mathcal{H}}$ is determined by a function $h \in \mathcal{H}$). Clearly, $\Psi_{\mathcal{H}}$ is a group under the composition with the inverse $\Psi_{h^{-1}} = \Psi_{h^{-1}}$ and the identity $\Psi_{\text{id}_{0,1}}$.

The mapping $\Psi : \mathcal{B} \times \mathcal{H} \to \mathcal{B}$ is the action of the group $\mathcal{H}$ on $\mathcal{B}$. Since $\Psi_h M = M$ for each $h \in \mathcal{H}$, then each $\Psi_h$-transform of a universal submeasure is a universal submeasure as well. Moreover, $\Theta_{L,M} = \Theta_{L,\Psi_h M}$ for each $(L, h) \in \mathcal{L} \times \mathcal{H}$. Also it is known, see [6] Proposition 2.6, that the class $\mathcal{F}$ of t-norms is closed under $\Psi$.

**Proposition 3.3** Let $h \in \mathcal{H}$. Then

(i) if $h$ is supermultiplicative, then for each $L_1, L_2 \in \mathcal{L}$ such that $L_1 \leq L_2$ holds $\Theta_{L_1,\Pi} \ll \Theta_{L_2,\Psi_h \Pi}$;

(ii) if the function $1 - h(1 - x)$ is subadditive, then for each $L_1, L_2 \in \mathcal{L}$ such that $L_1 \leq L_2$ holds $\Theta_{L_1, W} \ll \Theta_{L_2, \Psi_h W}$;

(iii) if $(L_1, T_1), (L_2, T_2) \in \mathcal{L} \times \mathcal{F}$ such that $\Theta_{L_1, T_1} \ll \Theta_{L_2, T_2}$, then $\Theta_{L_1, \Psi_h T_1} \ll \Theta_{L_2, \Psi_h T_2}$;

\[\text{A class } \mathcal{B} \text{ is closed under } \Psi, \text{ if } \Psi_h(\mathcal{B}) \subset \mathcal{B} \text{ for each } h \in \mathcal{H}\]
Example 3.4 Let \( \eta \) be a numerical submeasure on \( \Sigma \). If \( h(x) = \tan \frac{\pi}{4} x \) for \( x \in [0, 1] \), then for \( L \geq K_1 \) we get \( \gamma \in \Theta_{L,T} \), where
\[
\gamma_E(x) = \max \left\{ \min \left\{ \frac{4}{\pi} \arctan(1 - \eta(E) + x), 1 \right\}, 0 \right\}, \quad E \in \Sigma.
\]

It is easy to verify that the convex combination of numerical submeasures is again a numerical submeasure. If we consider the pseudo-convex combination in the spirit of weighted quasi-arithmetic mean, the result for probabilistic submeasures will be the same, i.e., for an arbitrary \( L \in \mathcal{L} \) the weighted quasi-arithmetic mean
\[
A^w_t(x_1, \ldots, x_n) = t^{-1} \left( \sum_{i=1}^n w_i t(x_i) \right)
\]
generated by an additive generator \( t \) of a continuous Archimedean t-norm \( T \in \mathcal{T} \) preserves the class \( \Theta_{L,T} \) of probabilistic \( \tau_{L,T} \)-submeasures. Here for \( i = 1, \ldots, n \) we consider \( x_i \in [0, 1] \), \( w_i \) are non-negative weights with \( \sum_{i=1}^n w_i = 1 \) and \( t^{-1} \) is the pseudo-inverse function to \( t \), see [13] for more details. Recall that \( t : [0,1] \to \mathbb{R}_+ \) is an additive generator of a continuous Archimedean t-norm \( T \) if and only if it is continuous, strictly decreasing and satisfying \( t(1) = 0 \). Moreover, its pseudo-inverse \( t^{-1} : \mathbb{R}_+ \to [0,1] \) is given by
\[
t^{-1}(x) = t^{-1}(\min\{t(0), x\}).
\]

Proposition 3.5 Let \( L \in \mathcal{L} \) and \( t \) be an additive generator of a continuous Archimedean t-norm \( T \in \mathcal{T} \). If \( \gamma^{(i)} \in \Theta_{L,T} \) for \( i = 1,2,\ldots,n \), then
\[
\gamma = A_t^w \left( \gamma^{(1)}, \ldots, \gamma^{(n)} \right) \in \Theta_{L,T}.
\]

**Proof.** The first two properties (a') and (b') of Definition 2.1 are easy to verify, therefore we show only the triangle inequality (c').

Let \( E, F \in \Sigma \). Since \( \gamma^{(i)} \in \Theta_{L,T} \), then
\[
\gamma^{(i)}_{E,F}(L(x,y)) \geq t^{-1} \left( \min \left\{ t(0), t \left( \gamma^{(i)}_E(x) \right) + t \left( \gamma^{(i)}_F(y) \right) \right\} \right), \quad x, y > 0,
\]
and we have
\[
\gamma_{E,F}(L(x,y)) = t^{-1} \left( \sum_{i=1}^n w_i t \left( \gamma^{(i)}_{E,F}(L(x,y)) \right) \right)
\]
\[
\geq t^{-1} \left( \sum_{i=1}^n w_i \min \left\{ t(0), t \left( \gamma^{(i)}_E(x) \right) + t \left( \gamma^{(i)}_F(y) \right) \right\} \right)
\]
\[
\geq t^{-1} \left( t(\gamma_E(x)) + t(\gamma_F(y)) \right)
\]
\[
= T(\gamma_E(x), \gamma_F(y)),
\]
thus \( \gamma \) is a \( \tau_{L,T} \)-submeasure on \( \Sigma \). \( \square \)
Corollary 3.6 Let $(L, h) \in \mathcal{L} \times \mathcal{M}$ and $t$ be an additive generator of a continuous Archimedean t-norm $T \in \mathcal{T}$. If $\gamma^{(i)} \in \Theta_{L, \Psi_k T}$ for $i = 1, 2, \ldots, n$, then

$$\gamma = A^w_t \left( \gamma^{(1)}, \ldots, \gamma^{(n)} \right) \in \Theta_{L, \Psi_k T}.$$  

From these observations we state the following open problem:

**Problem 2** Characterize the class of mappings (aggregation operators) $\mathcal{M}$ which preserve the class $\Theta_{L, A}$ of probabilistic submeasures for a fixed $(L, A) \in \mathcal{L} \times \mathcal{A}$, i.e., $\mathcal{M}(\Theta_{L, A}) \subseteq \Theta_{L, A}$.

As it is already known, see [12, Theorem 1], to each numerical submeasure $\eta$ on $\Sigma$ corresponds $\gamma \in \Theta_{L, M}$, $L \geq K_1$, in the form

$$\gamma_E(x) = \varepsilon_0(x - \eta(E)), \quad x > 0, E \in \Sigma,$$

where the number $\gamma_E(x)$ may be interpreted as the probability that the value of submeasure $\eta$ of a set $E \in \Sigma$ is less than $x$. To underline the interesting relationship between the probabilistic $\tau_{L, T}$-submeasure $\gamma$ and the numerical submeasure $\eta$ on $\Sigma$ we give the following result which improves and generalizes [12, Theorem 4]. For the sake of completeness we give its short direct proof here.

**Theorem 3.7** Let $L \leq K_1$ and $\gamma \in \Theta_{L, T_1}$. If $t$ is an additive generator of a continuous Archimedean t-norm $T$ such that $T \leq T_1$, then a mapping $\eta_{\gamma, t} : \Sigma \rightarrow \mathbb{R}_+$ given by

$$\eta_{\gamma, t}(E) = \sup\{z \in \mathbb{R}_+; t(\gamma_E(z)) \geq z\}$$

is a numerical submeasure.

**Proof.** The equality $\eta_{\gamma, t}(\emptyset) = 0$ and the monotonicity of $\eta_{\gamma, t}$ are obvious. Moreover, it is evident that $\gamma$ is an element of $\Theta_{K_1, T}$, and hence for $E, F \in \Sigma$ we have

$$\eta_{\gamma, t}(E \cup F) = \sup\{z \in \mathbb{R}_+; t(\gamma_{E \cup F}(z)) \geq z\}$$

$$\leq \sup\{z \in \mathbb{R}_+; t(T(\gamma_E(x), \gamma_F(z-x))) \geq x + z - x \text{ for some } x \in [0, z]\}$$

$$= \sup\{z \in \mathbb{R}_+; \min\{t(0), t(\gamma_E(x)) + t(\gamma_F(z-x))\} \geq z \text{ for some } x \in [0, z]\}$$

$$\leq \eta_{\gamma, t}(E) + \eta_{\gamma, t}(F),$$

which proves that $\eta_{\gamma, t}$ is a numerical submeasure on $\Sigma$. □

Now we will consider the Fréchet-Nikodym topology $\Gamma(\gamma)$ generated by probabilistic submeasure $\gamma$ on $\Sigma$. This notion was introduced and studied by Drewnowski in [3] for numerical submeasures on a ring of sets. Recall that a topology $\sigma$ on a ring $\Sigma$ is said to be a ring topology if the mappings $(E, F) \rightarrow E \Delta F$ and $(E, F) \rightarrow E \cap F$ of $\Sigma \times \Sigma \rightarrow \Sigma$ are continuous (with respect to the product topology on $\Sigma \times \Sigma$). A ring topology $\sigma$ is said to be a Fréchet-Nikodym topology on $\Sigma$ if for each $\sigma$-neighborhood $U$ of $\emptyset$ in $\Sigma$ there is a $\sigma$-neighborhood $V$ of $\emptyset$ in $\Sigma$ such that $F \subseteq U$ for all $F \subseteq E \in V$, $F \in \Sigma$. In particular, a family $\{\eta_i; i \in I\}$ of numerical submeasures on $\Sigma$ defines a Fréchet-Nikodym topology $\Gamma(\eta_i; i \in I)$ and conversely, for each Fréchet-Nikodym topology $\Gamma$ on $\Sigma$ there is a family $\{\gamma_j; j \in J\}$ of numerical submeasures on $\Sigma$ such that $\Gamma = \Gamma(\gamma_j; j \in J)$.
Define the set function $\rho : \Sigma \times \Sigma \to \Delta^+$ by $\rho(E, F) = \gamma_{E \triangle F}$ where $\gamma \in \Theta_{L,T}$. Then

$$\rho_{E,F}(L(x,y)) = \gamma_{E \triangle F}(L(x,y)) \geq \gamma_{(E \triangle G) \cup (G \triangle F)}(L(x,y))$$

$$\geq T(\gamma_{E \triangle G}(x), \gamma_{G \triangle F}(y)) = T(\rho_{E,G}(x), \rho_{G,F}(y)),$$

which means, in the other words, that $\rho$ is an $L$-Menger pseudo-metric on $\Sigma$. Moreover, $\rho$ is translation invariant, i.e.,

$$\rho_{E,F} = \gamma_{E \triangle F} = \gamma_{(E \triangle G) \cup (G \triangle F)} = \rho_{E,G,G,F}.$$ 

Thus, the triple $(\Sigma, \rho, \tau_{L,T})$ is an $L$-Menger probabilistic pseudo-metric space, see [11, Theorem 3.2]. Since for $E_1, E_2, F_1, F_2 \in \Sigma$ holds

$$(E_1 \cap F_1) \triangle (E_2 \cap F_2) \subseteq (E_1 \triangle E_2) \cup (F_1 \triangle F_2),$$

then we get

$$\rho_{E_1 \cap F_1, E_2 \cap F_2}(x) = \gamma_{(E_1 \cap F_1) \triangle (E_2 \cap F_2)}(x) \geq \gamma_{(E_1 \triangle E_2) \cup (F_1 \triangle F_2)}(L(z))$$

$$\geq T(\gamma_{E_1 \triangle E_2}(z), \gamma_{F_1 \triangle F_2}(z)) = T(\rho_{E_1,E_2}(z), \rho_{F_1,F_2}(z)),$$

where $L(z, z) < x$. If $(E_n, F_n) \to (E, F)$ in topology $\Gamma(\gamma)$, then $E_n \to E$ and $F_n \to F$. Thus, $\rho_{E_n,E}(z) \to 1$ and $\rho_{F_n,F}(z) \to 1$. Moreover, if we consider a continuous t-norm $T$, then from (2) we get $\rho_{E_n \cap E, F_n \cap F}(z) \to 1$ for each $x > 0$. In fact, it proves continuity of $\cap$ in the product topology $\Sigma \times \Sigma$. These observations lead to the following result.

**Proposition 3.8** Let $(L, T) \in \mathcal{L} \times \mathcal{F}$, where $T$ is a continuous t-norm and $\gamma \in \Theta_{L,T}$. For $\varepsilon > 0$ and $\delta > 0$ put

$$\mathcal{B}(\varepsilon, \delta) = \{ E \in \Sigma; \, \gamma_{E}(\varepsilon) > 1 - \delta \}.$$ 

Then

(i) $\mathcal{B} = \{ \mathcal{B}(\varepsilon, \delta); \, \varepsilon > 0, \delta > 0 \}$ is a normal base of neighborhoods of $\emptyset$ for the Fréchet-Nikodym topology $\Gamma(\gamma)$;

(ii) $(\Sigma, \triangle, \cap, \Gamma(\gamma))$ is a topological ring of sets.

4 Semi-copula-based submeasures

In what follows we consider the natural extension/modification of t-norms: copulas, quasi-copulas and semi-copulas, see [5]. Recall that a semi-copula is an aggregation function $S : [0, 1]^2 \to [0, 1]$ with 1 as its neutral element. Denote by $\mathcal{F}$ the set of all semi-copulas and $\mathcal{F}$ the set of all continuous semi-copulas. A quasi-copula $Q$ is a 1-Lipschitz semi-copula, i.e., a semi-copula $Q$ satisfying

$$|Q(x, y) - Q(x', y')| \leq |x - x'| + |y - y'|$$

for all $x, x', y, y' \in [0, 1]$. The set of all quasi-copulas will be denoted by $\mathcal{Q}$. A semi-copula $C$ which is 2-increasing, i.e., for each $x, y, x', y' \in [0, 1]$ such that $x \leq x'$ and $y \leq y'$ holds

$$C(x', y') - C(x, y') - C(x', y) + C(x, y) \geq 0,$$
is called a copula. Denote by \( C \) the set of all copulas. Then \( C \subset \mathcal{Q} \subset \mathcal{I} \). All these sets are partially ordered equipped with the usual point-wise order \( \leq \) between real functions. Clearly, for each \( h \in \mathcal{H} \) the mapping \( \Psi_h \) is order-preserving on \( \mathcal{I} \) and for a given \( h \in \mathcal{H} \) the partially ordered set

\[ \mathcal{K} = \{ S \in \mathcal{I}; \Psi_h S = S \}, \leq \]

is a complete lattice (by Knaster-Tarski theorem). As we have already mentioned, \( M \in \mathcal{K} \), but also \( D \in \mathcal{K} \).

For the class of Archimedean copulas, i.e., copulas of the form

\[ C(x, y) = \varphi^{-1}(\varphi(x) + \varphi(y)) \]

for all \( x, y \in [0, 1] \) where \( \varphi : [0, 1] \to [-\infty, +\infty] \) is a continuous, strictly decreasing convex function with \( \varphi(1) = 0 \) and the pseudo-inverse \( \varphi^{-1} \) (such a function is called an additive generator of \( C \), cf. [14]) we immediately have the following characterization.

**Proposition 4.1** Let \( \eta \) be a numerical submeasure on \( \Sigma \). If \( \varphi \) is an additive generator of \( C \in \mathcal{C} \), then \( \gamma \in \Theta_C \), where

\[ \gamma_E(x) = \varphi^{-1}(\eta(E) - x), \quad E \in \Sigma. \]

Moreover, for each \( h \in \mathcal{H} \) holds \( \gamma \in \Theta_{\Psi h C} \), where

\[ \gamma_E(x) = (\varphi \circ h)^{-1}(\eta(E) - x), \quad E \in \Sigma. \]

Easily it is possible to state the analogous result for the multiplicative generator of \( C \in \mathcal{C} \).

**Example 4.2** Let \( \eta \) be a numerical submeasure on \( \Sigma \) and \( E \in \Sigma \). Then

(i) \( \gamma \in \Theta_{C_{GH}^\lambda} \), where

\[ \gamma_E(x) = \exp \left( - \left[ \max\{ \eta(E) - x, 0 \} \right]^{1/\lambda} \right) \]

corresponds to the Gumbel-Hougaard family of (strict) copulas \( C_{GH}^\lambda \) given by

\[ C_{GH}^\lambda(u, v) = \exp \left( - \left[ (\ln u)^\lambda + (\ln v)^\lambda \right]^{1/\lambda} \right), \]

with \( \lambda \in [1, +\infty[ \), see [14]: for \( \lambda = 1 \) we have the independence copula \( \Pi \) (and the corresponding \( \gamma \in \Theta_{\Pi} \)) – clearly, \( \Theta_{\Pi} \in \Theta_{\mathcal{C}} \) and for each \( h \in \mathcal{H} \) we have \( \Theta_{\Psi h \Pi} \in \Theta_{\mathcal{F}} \); (ii) \( \gamma \in \Theta_{\mathcal{C}^\lambda} \), where

\[ \gamma_E(x) = \max \left\{ \min \left\{ \frac{1 - \eta(E) + x}{1 + (\lambda - 1)(\eta(E) - x)}, 1 \right\}, 0 \right\} \]

corresponds to the family of (non-strict) copulas

\[ C_{\lambda}(u, v) = \max \left\{ \frac{\lambda^2 uv - (1 - u)(1 - v)}{\lambda^2 - (\lambda - 1)^2(1 - u)(1 - v)}, 0 \right\}, \quad \lambda \in [1, +\infty[. \]
Observe that similarly as in the case of t-norms \( \mathcal{I} \), the weighted quasi-arithmetic mean

\[
A^w_\varphi(x_1, \ldots, x_n) = \varphi^{-1}\left(\sum_{i=1}^n w_i \varphi(x_i)\right)
\]
generated by an additive generator \( \varphi \) of an Archimedean copula \( C \in \mathcal{C} \) preserves the class \( \Theta_C \) of probabilistic copula-based submeasures (even their generalization involving an arbitrary \( L \in \mathcal{L} \)).

Given a class \( \mathcal{R} \) of functions from \([0, 1]^2\) to \([0, 1]\), we shall denote by \( \Psi_{\mathcal{R}}(\mathcal{R}) \) the class of operators obtained by transforming all elements of \( \mathcal{R} \) by all elements of \( \Psi_{\mathcal{R}} \). Since the classes \( \mathcal{I} \) and \( \mathcal{I}_c \) are closed under \( \Psi \), cf. [3], we have the following relations

\[
\Psi_{\mathcal{R}}(\mathcal{C}) \subset \Psi_{\mathcal{R}}(\mathcal{D}) \subset \Psi_{\mathcal{R}}(\mathcal{I}_c) = \mathcal{I}_c \subset \mathcal{I} = \Psi_{\mathcal{R}}(\mathcal{I}).
\]

Recall that the identity \( I \in \Psi_{\mathcal{R}} \). Moreover, \( \mathcal{C} \subset \Psi_{\mathcal{R}}(\mathcal{C}) \) and \( \mathcal{D} \subset \Psi_{\mathcal{R}}(\mathcal{D}) \), see [1].

**Proposition 4.3** If \( S_1, S_2 \in \mathcal{I} \) such that \( \Theta_{S_1} \ll \Theta_{S_2} \), then for each \( h \in \mathcal{H} \) it holds \( \Theta_{\Psi_h S_1} \ll \Theta_{\Psi_h S_2} \). Moreover, \( \Theta_{\mathcal{I}} = \Theta_{\Psi_{\mathcal{R}}(\mathcal{I})} \) and \( \Theta_{\mathcal{I}_c} = \Theta_{\Psi_{\mathcal{R}}(\mathcal{I}_c)} \).

In what follows we are interested in lattice structure of submeasure spaces in \( \Theta_{\mathcal{I}} \). As shown in [7], the class \( \mathcal{I} \) of semi-copulas constitutes the lattice completion of the class \( \mathcal{I} \) of t-norms, in the sense that every semi-copula may be represented as the point-wise supremum and infimum of a suitable subset of t-norms. Let \( \vee \) and \( \wedge \) denote the point-wise supremum and infimum, respectively. Observe that if \( \gamma \) is a \( \tau_{S_1} \)- and \( \tau_{S_2} \)-submeasure for some \( S_1, S_2 \in \mathcal{I} \), then \( \gamma \) is a \( \tau_{S_1 \vee S_2} \)- as well as \( \tau_{S_1 \wedge S_2} \)-submeasure. Thus, for \( S_1, S_2 \in \mathcal{I} \) put

\[
\Theta_{S_1} \cup \Theta_{S_2} = \Theta_{S_1 \vee S_2} \quad \text{and} \quad \Theta_{S_1} \cap \Theta_{S_2} = \Theta_{S_1 \wedge S_2}.
\]

It is easy to see that \( \cup \) and \( \cap \) are lattice operations. Since \( (\mathcal{I}, \leq, \vee, \wedge) \) is a complete lattice, see [7], then we have the following observation.

**Proposition 4.4** The family \( \Theta_{\mathcal{I}} \) of all probabilistic submeasure spaces is a distributive lattice.

**Proof.** Indeed, for \( S_1, S_2, S_3 \in \mathcal{I} \), we have:

\[
\Theta_{S_1} \cup (\Theta_{S_2} \cap \Theta_{S_3}) = \Theta_{S_1} \cup \Theta_{S_2 \vee S_3} = \Theta_{S_1 \wedge (S_2 \vee S_3)} = \Theta_{(S_1 \wedge S_2) \vee (S_1 \wedge S_3)}
\]

\[
= \Theta_{S_1 \wedge S_2} \cap \Theta_{S_1 \wedge S_3} = (\Theta_{S_1} \cup \Theta_{S_2}) \cap (\Theta_{S_1} \cup \Theta_{S_3}).
\]

Analogously for \( \Theta_{S_1} \cap (\Theta_{S_2} \cup \Theta_{S_3}) \). By [2] Theorem 2.2 \( \Theta_{\mathcal{I}} \) is a distributive lattice. \( \square \)

Since for each \( S \in \mathcal{I} \) holds \( \Theta_M \ll \Theta_S \ll \Theta_D \), then \( \Theta_M \) is bottom and \( \Theta_D \) is top in the lattice \( \Theta_{\mathcal{I}} \), thus \( \Theta_{\mathcal{I}} \) is a bounded distributive lattice.

**Proposition 4.5** For every \( S_1 \in \mathcal{I} \), the set

\[
\mathcal{I}_{S_1} = \{ \Theta_S \in \Theta_{\mathcal{I}} ; \Theta_S \ll \Theta_{S_1}, S \in \mathcal{I} \}
\]

is an ideal in \( \Theta_{\mathcal{I}} \).
Proof. First, observe that for \( S_1 \in \mathcal{S} \) the set \( \mathcal{I}_{S_1} \) is the set of all \( \tau_{S} \)-submeasures related to a semi-copula \( S \) which are also \( \tau_{S_1} \)-submeasures.

Let \( \Theta_{S_2} \in \mathcal{I}_{S_1} \), i.e., \( \Theta_{S_2} \ll \Theta_{S_1} \) and let \( \Theta_{S_1} \ll \Theta_{S_2} \). From it follows that \( S_1 \leq S_2 \) and \( S_2 \leq S_3 \). Thus, \( S_1 \leq S_3 \) which shows that \( \Theta_{S_3} \ll \Theta_{S_1} \), i.e., \( \Theta_{S_3} \in \mathcal{I}_{S_1} \).

Let \( \Theta_{S_2}, \Theta_{S_3} \in \mathcal{I}_{S_1} \), i.e., \( S_1 \leq S_2 \) and \( S_1 \leq S_3 \). Since \( S_1 \leq S_2 \land S_3 \), then \( \Theta_{S_2} \lor \Theta_{S_3} = \Theta_{S_2 \land S_3} \ll \Theta_{S_1} \), i.e., \( \Theta_{S_2} \lor \Theta_{S_3} \in \mathcal{I}_{S_1} \). Therefore, \( \mathcal{I}_{S_1} \) is an ideal in \( \Theta_{\mathcal{S}} \).

Dually to Theorem 4.5, we obtain the following corollary.

**Corollary 4.6** For every \( S_2 \in \mathcal{S} \), the set
\[
\mathcal{F}_{S_2} = \{ \Theta_S \in \Theta_{\mathcal{S}}; \Theta_S \ll \Theta_{S_2}, S \in \mathcal{S} \}
\]
is a filter in \( \Theta_{\mathcal{S}} \).

From it follows that for \( S_1, S_2 \in \mathcal{S} \) such that \( S_1 \leq S_2 \) the set
\[
[\Theta_{S_2}, \Theta_{S_1}] = \mathcal{I}_{S_1} \cap \mathcal{F}_{S_2}
\]
is an order interval in \( \Theta_{\mathcal{S}} \).

**Theorem 4.7** \((\Theta_{\mathcal{S}}, \ll, \lor, \land, \Theta_D, \Theta_M)\) is a complete lattice.

Proof. Let \( \Theta_{\mathcal{S}} \) be any subset of \( \Theta_{\mathcal{S}} \) and put
\[
\lor \Theta_{\mathcal{S}} = \Theta_{\lor \mathcal{S}}, \land \Theta_{\mathcal{S}} = \Theta_{\land \mathcal{S}}, \Theta_D = \Theta_{\lor \mathcal{S}}, \Theta_M = \Theta_{\land \mathcal{S}}
\]
where
\[
\lor \mathcal{P}(x, y) = \sup \{ P(x, y); P \in \mathcal{P} \} \quad \land \mathcal{P}(x, y) = \inf \{ P(x, y); P \in \mathcal{P} \}
\]
for each \( (x, y) \in [0,1]^2 \). Since \((\mathcal{S}, \leq, \lor, \land)\) is complete, then for each \( \mathcal{P} \subseteq \mathcal{S} \) holds \( \lor \mathcal{P} \subseteq \mathcal{S} \) and \( \land \mathcal{P} \subseteq \mathcal{S} \). Thus \( \Theta_{\lor \mathcal{S}} \in \Theta_{\mathcal{S}} \) and \( \Theta_{\land \mathcal{S}} \in \Theta_{\mathcal{S}} \).

**Remark 4.8** Since \((\mathcal{Q}, \leq, \lor, \land)\) is a complete lattice, see [15], all the above assertions hold also for \( \Theta_{\mathcal{Q}}, \) i.e., \((\Theta_{\mathcal{Q}}, \ll, \lor, \land, \Theta_W, \Theta_M)\) is a complete sublattice of \((\Theta_{\mathcal{S}}, \ll, \lor, \land, \Theta_D, \Theta_M)\), where for each \( Q_1 \in \mathcal{Q} \) the set
\[
\mathcal{J}_{Q_1} = \{ \Theta_Q \in \Theta_{\mathcal{Q}}; \Theta_Q \ll \Theta_{Q_1}, Q \in \mathcal{Q} \}
\]
is an ideal in \( \Theta_{\mathcal{Q}} \) and for each \( Q_2 \in \mathcal{Q} \), the set
\[
\mathcal{F}_{Q_2} = \{ \Theta_Q \in \Theta_{\mathcal{Q}}; \Theta_{Q_2} \ll \Theta_Q, Q \in \mathcal{Q} \}
\]
is a filter in \( \Theta_{\mathcal{Q}} \).

**Acknowledgement**

This work was partially supported by research grants APVV-0073-10 and P402/11/0378. The second author has been on a postdoctoral stay at the Departamento de Matemáticas, CINVESTAV del IPN (México) when investigating some parts of the work presented therein and finishing the paper. He therefore gratefully acknowledges the hospitality and support of the mathematics department of CINVESTAV on this occasion and partial support of the Research Project VVGS 45/10-11.
