Optimization-based Decentralized Coded Caching for Files and Caches with Arbitrary Sizes

Qi Wang, Ying Cui, Sian Jin, Junni Zou, Chenglin Li, Hongkai Xiong

Abstract

Existing decentralized coded caching solutions cannot guarantee small loads in the general scenario with arbitrary file sizes and cache sizes. In this paper, we propose an optimization framework for decentralized coded caching in the general scenario to minimize the worst-case load and average load (under an arbitrary file popularity), respectively. Specifically, we first propose a class of decentralized coded caching schemes for the general scenario, which are specified by a general caching parameter and include several known schemes as special cases. Then, we optimize the caching parameter to minimize the worst-case load and average load, respectively. Each of the two optimization problems is a challenging nonconvex problem with a nondifferentiable objective function. For each optimization problem, we develop an iterative algorithm to obtain a stationary point using techniques for solving Complementary Geometric Programming (GP). We also obtain a low-complexity approximate solution by solving an approximate problem with a differentiable objective function which is an upper bound on the original nondifferentiable one, and characterize the performance loss caused by the approximation. Finally, we present two information-theoretic converse bounds on the worst-case load and average load (under an arbitrary file popularity) in the general scenario, respectively. To the best of our knowledge, this is the first work that provides optimization-based decentralized coded caching schemes and information-theoretic converse bounds for the general scenario.

I. Introduction

Recently, a new class of caching schemes for content placement in user caches, referred to as coded caching [1], have received significant interest. In [1], Maddah-Ali and Niesen consider a system consisting of one server with access to a library of files and connected through a shared, error-free link to multiple users each with a cache. Each user can obtain the requested file based on the received multicast message and the contents stored in its cache. They formulate a caching problem, consisting of two phases, i.e., uncoded content placement and coded content delivery, which has been successfully investigated in a large number of recent works [1]–[11] under the same network setting.

In [1]–[3], the authors propose centralized coded caching schemes to minimize the worst-case load (over all possible requests) [1] or average load (over random requests) [2], [3] of the shared link in the delivery phase. Specifically, in [1], Maddah-Ali and Niesen propose a centralized coded caching scheme to minimize the worst-case load and show that it achieves order-optimal memory-load tradeoff. In [2], Jin et al. consider a class of centralized coded caching schemes specified by a general file partition parameter, and optimize the parameter to minimize the average load within the class under an arbitrary file popularity. In [3], a parameter-based coded caching design approach similar to the one in [2] is adopted to minimize the average load under an arbitrary file popularity in the scenario with arbitrary file sizes and two different cache sizes. Centralized coded caching schemes have limited practical applicability, as they require a centrally coordinated placement phase depending on the exact number of active users in the delivery phase, which is actually not known when placing content in a practical network.

Decentralized coded caching schemes [4]–[11], where the exact number of active users in the delivery phase is not required and the cache of each user is filled independently of the other users, are then considered to minimize the worst-case load [4], [9]–[11] or average load [5]–[8]. In [4], Maddah-Ali and Niesen propose a decentralized coded caching scheme to minimize the worst-case load and show that it achieves order-optimal memory-load trade-off. In [5], files are partitioned into multiple groups and the decentralized coded caching scheme in [4] is applied to each group to reduce the average load. As coded-multicasting opportunities for files from different groups are not explored, the resulting average load may not be desirable. In [6], the authors optimize the memory allocation for files by minimizing an upper bound on the average load.
As the optimization problem is highly non-convex and not amenable to analysis, [6] proposes a simpler suboptimal scheme, referred to as the RLFU-GCC scheme, where all files are partitioned into two groups and the GCC$_1$ procedure is applied to the group of popular files. In [7], inspired by the RLFU-GCC scheme in [6], Zhang et al. present a decentralized coded caching scheme, where all files are partitioned into two groups and the delivery procedure of Maddah-Ali-Niesen’s decentralized scheme is applied to the group of popular files. In [8], Wang et al. formulate a coded caching design problem to minimize the average load by optimizing the cache memory allocation for files. The optimization problem is nonconvex, and a low-complexity approximate solution is obtained by solving an approximate convex problem of the original problem. Note that [4]–[8] all consider the scenario where all files have the same file size and all users have the same cache size, and the resulting schemes may not achieve small loads when file sizes or cache sizes are different. In contrast, [9] considers the scenario with arbitrary cache sizes and the same file size, while [10] and [11] consider the scenario with arbitrary file sizes and the same cache size. More specifically, the decentralized coded caching schemes proposed in [9] and [10] are not optimization based, and the decentralized coded caching scheme in [11] is obtained by solving an approximate problem of the worst-case load minimization problem without any performance guarantee. Thus, the existing solutions in [9]–[11] may not guarantee small loads in the general scenario with arbitrary file sizes and cache sizes.

Besides achievable schemes, information-theoretic converse bounds on the worst-case load [1], [9], [10], [12]–[17] and average load [2], [5]–[8], [12], [13], [16], [17] for coded caching are presented. The converse bounds in [1], [2], [5]–[10], [12]–[17] can be classified into two classes, i.e., class i): bounds that are applicable only to uncoded placement and class ii): bounds that are applicable to any placement (including uncoded placement and coded placement). The converse bound in [12] belongs to class i) and is exactly tight for both the worst-case load and average load. The converse bounds derived based on reduction from an arbitrary file popularity to the uniform file popularity [2], [5]–[7], cut-set [1], [8]–[10], [14], association with a combinatorial problem of optimally labeling the leaves of a directed tree [15], relation between a multi-user single request caching network and a single-user multi-request caching network [13], and other information-theoretic approaches [16], [17], belong to class ii). Note that the converse bounds in [1], [2], [5]–[9], [12]–[17] are for the scenario with the same file size and the converse bounds in [1], [2], [5]–[8], [10], [12]–[17] are for the scenario with the same cache size, and
hence cannot bound the minimum worst-case load or average load in the general scenario with arbitrary file sizes and arbitrary cache sizes.

In this paper, we consider the general scenario with arbitrary file sizes and cache sizes, and propose an optimization framework for decentralized coded caching in the general scenario to minimize the worst-case load and average load. We also present two information-theoretic converse bounds on the worst-case load and average load (under an arbitrary file popularity), respectively, applicable to any placement in the general scenario. To our knowledge, this is the first work that provides optimization-based decentralized coded caching schemes and information-theoretic converse bounds for the general scenario. Our detailed contributions are summarized below.

- We propose a class of decentralized coded caching schemes utilizing general uncoded placement and a specific coded delivery, which are specified by a general caching parameter. The considered class of decentralized coded caching schemes include the schemes in [4]–[8] (designed for the scenario with the same file size and cache size), the scheme in [9] (designed for the scenario with arbitrary cache sizes and the same file size) and the schemes in [10] and [11] (designed for the scenario with arbitrary file sizes and the same cache size) as special cases. Then, we formulate two parameter-based coded caching design optimization problems over the considered class of schemes to minimize the worst-case load and average load, respectively, by optimizing the caching parameter. Each problem is a challenging nonconvex problem with a nondifferentiable objective function.

- For each optimization problem, we develop an iterative algorithm to obtain a stationary point by equivalently transforming the nonconvex problem to a Complementary Geometric Programming (GP) and using techniques for Complementary GP. We also obtain a low-complexity approximate solution with performance guarantee, by bounding the original nondifferentiable objective function with two differentiable functions and solving an approximate problem with the differentiable upper bound as the objective function.

- We present two information-theoretic converse bounds on the worst-case load and average load (under an arbitrary file popularity), respectively, which are applicable to any placement (including uncoded placement and coded placement) in the general scenario. In the scenario with the same file size and the same cache size, the proposed converse bounds on the worst-case load and average load reduce to the two bounds in [17] and the one in [2], respectively.
• Numerical results show that the proposed solutions achieve significant gains over the schemes in [4], [9]–[11] and the schemes in [5]–[8] in the general scenario in terms of the worst-case load and average load, respectively. These results highlight the importance of designing optimization-based decentralized coded caching schemes for the general scenario.

II. PROBLEM SETTING

We consider a system with one server connected through a shared, error-free link to \( L \in \mathbb{N} \) users (including both active and inactive ones), each with an isolated cache memory (see Fig. 1) [4], where \( \mathbb{N} \) denotes the set of all positive integers.\(^1\) Let \( \mathcal{L} \triangleq \{1, 2, \ldots, L\} \) denote the set of user indices. User \( l \in \mathcal{L} \) has an isolated cache memory of size \( M_l \) data units, where \( M_l \in \left[0, \sum_{n=1}^{N} V_n\right] \). Let \( \bm{M} \triangleq (M_l)_{l \in \mathcal{L}} \) denote the cache sizes of all \( L \) users. Let \( T \) denote the cardinality of set \( \{M_l : l \in \mathcal{L}\} \). That is, there are \( T \) different values of the cache sizes for the \( L \) users, denoted by \( \overline{M}_1, \overline{M}_2, \ldots, \overline{M}_T \). Without loss of generality, we assume \( \overline{M}_1 < \overline{M}_2 < \cdots < \overline{M}_T \). Denote \( \mathcal{T} \triangleq \{1, 2, \ldots, T\} \). For all \( t \in \mathcal{T} \), let \( \mathcal{L}_t \triangleq \{l \in \mathcal{L} : M_l = \overline{M}_t\} \) denote the set of user indices for the users whose cache sizes are \( \overline{M}_t \). Let \( L_t \triangleq |\mathcal{L}_t| \) denote the cardinality of set \( \mathcal{L}_t \). The server has access to a library of \( N \in \mathbb{N} \) files, denoted by \( W_1, \ldots, W_N \). Let \( \mathcal{N} \triangleq \{1, 2, \ldots, N\} \) denote the set of file indices. File \( n \in \mathcal{N} \) consists of \( V_n \) indivisible data units. Let \( \bm{V} \triangleq (V_n)_{n \in \mathcal{N}} \) denote the file sizes of all \( N \) files. We assume that each user randomly and independently requests a file in \( \mathcal{N} \) according to an arbitrary file popularity. In particular, a user requests file \( n \) with probability \( p_n \in [0, 1] \), where \( n \in \mathcal{N} \). Thus, the file

\(^1\)Note that the server can be a base station, and each user can be a mobile device or a small base station.
For a coded caching scheme defined by an encoding function \( \psi \) in \([4]–[11]\), active user \( l \). Let \( L \) be the set of active users. Let \( \phi \) denote the caching functions of all the users. In the delivery phase, a subset of \( L_a \) active users is active, denoted by \( L_a \subseteq L \), and each active user in \( L_a \) randomly and independently requests one file in \( N \) according to the file popularity distribution \( p \). For all \( t \in T \), let \( L_{a,t} \triangleq \{ l \in L_a : M_l = M_t \} \) denote the set of user indices for the active users whose cache sizes are \( M_t \). Let \( L_{a,t} = |L_{a,t}| \) denote the cardinality of set \( L_{a,t} \). Thus, \( L_a = \sum_{t \in T} L_{a,t} \).

Denote \( L_a \triangleq (L_{a,t})_{t \in T} \). Let \( d_t \in N \) denote the index of the file requested by active user \( l \in L_a \), and let \( d_a \triangleq (d_t)_{t \in L_a} \in N^{L_a} \) denote the requests of the \( L_a \) active users. The server replies to these \( L_a \) requests by sending a multicast message over the shared link, observed by all \( L_a \) active users. Let \( \psi_a \) denote the server encoding function, which maps the files \( W_1, \ldots, W_N \), cache contents \( Z_a \triangleq (Z_l)_{l \in L_a} \) of the \( L_a \) active users and requests \( d_a \) into the multicast message \( Y \triangleq \psi_a(W_1, \ldots, W_N, Z_a, d_a) \) sent by the server over the shared link. Let \( \mu_t \) denote the decoding function for active user \( l \in L_a \), which maps the multicast message \( Y \) received over the shared link, the cache content \( Z_l \) and the request \( d_l \) to the estimate \( \hat{W}_{d_l} \) of the requested file \( W_{d_l} \) of active user \( l \in L_a \). Let \( \mu_a \triangleq (\mu_t)_{t \in L_a} \) denote the decoding functions of all the \( L_a \) active users.

For a coded caching scheme defined by an encoding function \( \psi_a \), caching functions \( \phi_a \) and decoding functions \( \mu_a \), the probability of error is defined as

\[
P_e(\psi_a, \phi_a, \mu_a) \triangleq \max_{d_a \in \mathbb{N}^{L_a}} \max_{l \in L_a} \Pr[\hat{W}_{d_l} \neq W_{d_l}] < \epsilon.
\]

A coded caching scheme is called \textit{admissible} if for every \( \epsilon > 0 \) and every large enough \( V \) as in \([4]–[11]\), \( P_e(\psi_a, \phi_a, \mu_a) \leq \epsilon \). Since the shared link is error free, such admissible schemes exist...
for sure. Given an admissible coded caching scheme $\mathcal{F}$ and the requests $d_a$ of all the $L_a$ active users, let $R(\mathcal{L}_a, N, V, M, \mathcal{F}, d_a)$ be the length (expressed in data units) of the multicast message $Y$, where $R(\mathcal{L}_a, N, V, M, \mathcal{F}, d_a)$ represents the load of the shared link. Let
\[
R_{\text{wst}}(\mathcal{L}_a, N, V, M, \mathcal{F}) \triangleq \max_{d_a \in N^{L_a}} R(\mathcal{L}_a, N, V, M, \mathcal{F}, d_a)
\]
denote the worst-case load of the shared link. Let
\[
R_{\text{avg}}(\mathcal{L}_a, N, V, M, \mathcal{F}) \triangleq \mathbb{E}[R(\mathcal{L}_a, N, V, M, \mathcal{F}, d_a)]
\]
denote the average load of the shared link, where the average is taken over random requests.\(^2\)

Let
\[
R_{\text{wst}}^*(\mathcal{L}_a, N, V, M) \triangleq \min_{\mathcal{F}} R(\mathcal{L}_a, N, V, M, \mathcal{F})
\]
and
\[
R_{\text{avg}}^*(\mathcal{L}_a, N, V, M) \triangleq \min_{\mathcal{F}} R(\mathcal{L}_a, N, V, M, \mathcal{F})
\]
denote the minimum achievable worst-case load and the minimum achievable average load of the shared link, where the minimum is taken over all admissible coded caching schemes. In this paper, we adopt the coded delivery strategy (i.e., encoding function $\psi_a$ and decoding functions $\mu_a$) in [4], and wish to optimize the uncoded placement strategy (i.e., caching functions $\phi_a$) for decentralized coded caching to minimize the worst-case load and average load of the shared link in the delivery phase, in the general scenario with arbitrary file sizes $V$ and arbitrary cache sizes $M$.

### III. PARAMETER-BASED DECENTRALIZED CODED CACHING

In this section, we first present a class of decentralized coded caching schemes for the general scenario with arbitrary file sizes and cache sizes, which are specified by a general caching parameter. Then, we derive the expressions of the worst-case load and average load as functions of the caching parameter for the class of schemes.

\(^2\)Later, we shall use different notations for the worst-case load and average load to reflect the dependency on the specific schemes considered.
In the placement phase (involving all $L$ users), for all $t \in \mathcal{T}$, each user $l \in \mathcal{L}_t$ independently caches a subset of $q_{t,n}V_n$ data units of file $n$, chosen uniformly at random, where

$$0 \leq q_{t,n} \leq 1, \quad \forall t \in \mathcal{T}, \quad n \in \mathcal{N}, \quad (3)$$

$$\sum_{n=1}^{N} q_{t,n}V_n \leq M_t, \quad \forall t \in \mathcal{T}. \quad (4)$$

Note that (4) represents the cache memory constraint. The caching parameter $\mathbf{q} \triangleq (q_{t,n})_{t \in \mathcal{T}, n \in \mathcal{N}}$ is a design parameter and will be optimized subject to the constraints in (3) and (4) to minimize the worst-case load and average load in Section IV and Section V, respectively. The general uncoded placement strategy parameterized by $\mathbf{q}$ extends those in [4] ($T = 1$ and $q_{1,n}, n \in \mathcal{N}$ are the same), [9] ($q_{t,n}, n \in \mathcal{N}$ are the same, for all $t \in \mathcal{T}$) and [5]–[8], [10], [11] ($T = 1$). As in [4]–[11], the random uncoded placement procedure can be operated in a decentralized manner in the sense that the exact number of active users in the delivery phase is not required and the cache of each user is filled independently of the other users.

The coded delivery procedure (involving the $L_a$ active users) is the same as those in [4], [8]–[11] and is briefly presented here for completeness. Let $W_{d_l,S}$ denote the data units of file $d_l$ requested by active user $l \in \mathcal{L}_a$ that are cached exclusively at the active users in $S \subseteq \mathcal{L}_a$ (i.e., every data unit in $W_{d_l,S}$ is present in the cache of every active user in $S$ and is absent from the cache of every active user outside $S$). For any $S \subseteq \mathcal{L}_a$ of cardinality $|S| = s \in \{1, 2, \ldots, L_a\}$, the server transmits coded-multicast message $\oplus_{l \in S} W_{d_l,S \setminus \{l\}}$, where operator $\oplus$ denotes componentwise XOR. All elements in the coded-multicast message are assumed to be zero-padded to the length of the longest element. For all $s \in \{1, 2, \ldots, L_a\}$, we conduct the above delivery procedure. The multicast message for the $L_a$ active users is simply the concatenation of the coded-multicast messages for all $s \in \{1, 2, \ldots, L_a\}$. By the proof of Theorem 1 in [4], we can conclude that each active user $l \in \mathcal{L}_a$ is able to decode the requested file based on the received multicast message and its cache content.

Now we formally summarize the placement and delivery procedures of the class of the decentralized coded caching schemes specified by the general caching parameter $\mathbf{q}$ in Algorithm 1. By Algorithm 1 and [4], we can calculate the worst-case load for the $L_a$ active users in $\mathcal{L}_a$ under
Algorithm 1 Parameter-based Decentralized Coded Caching

**Input:** $q = (q_t,n)_{t \in T, n \in N}$

**Placement procedure**

1: for $t \in T$ do  
2: for $l \in L_t, n \in N$ do  
3: user $l$ independently caches a subset of $q_{t,n}V_n$ data units of file $n$, chosen uniformly at random  
4: end for  
5: end for

**Delivery procedure** [4]

1: for $s \in \{1,2,\ldots,L_a\}$ do  
2: for $S \subseteq \mathcal{L}_a : |S| = s$ do  
3: Server sends $\oplus_{l \in S}W_{d_l,S\{l\}}$  
4: end for  
5: end for

Given caching parameter $q$ as follows:

$$\max_{d_a \in \mathcal{N}^{L_a}} \sum_{s=1}^{L_a} \sum_{S \subseteq \mathcal{L}_a: |S| = s} \max_{l \in S} \left( \prod_{a \in S \setminus \{l\}} \prod_{t \in \mathcal{L}_a,t} q_{t,d_l} \right) \left( \prod_{b \in \mathcal{L}_a \setminus (S \setminus \{l\})} \prod_{t \in \mathcal{L}_a,t} (1 - q_{t,d_l}) \right) V_{d_l}, \quad (5)$$

where $\max_{l \in S} \left( \prod_{a \in S \setminus \{l\}} \prod_{t \in \mathcal{L}_a,t} q_{t,d_l} \right) \left( \prod_{b \in \mathcal{L}_a \setminus (S \setminus \{l\})} \prod_{t \in \mathcal{L}_a,t} (1 - q_{t,d_l}) \right) V_{d_l}$ represents the length of the coded-multicast message $\oplus_{l \in S}W_{d_l,S\{l\}}$. It is clear that the expression in (5) is a function of $\mathcal{L}_a = (\mathcal{L}_a,t)_{t \in T}$, library size $N$, file sizes $V$ and caching parameter $q$, and can be rewritten as

$$R_{\text{west}}(\mathcal{L}_a, N, V, q) \triangleq \max_{n \in \mathcal{N}^{L_a}} \sum_{s=1}^{L_a} \sum_{S \subseteq \{1,\ldots,L_a\}: |S| = s} \max_{j \in S} \left( \prod_{a \in S \setminus \{j\}} \prod_{t \in \mathcal{T}(\mathcal{L}_a)} q_{t,n_j} \right) \left( \prod_{b \in \{1,\ldots,L_a\} \setminus \mathcal{T}(\mathcal{L}_a)} \prod_{t \in \mathcal{T}(\mathcal{L}_a)} (1 - q_{t,n_j}) \right) V_{n_j}, \quad (6)$$

where $L_a = \sum_{t \in \mathcal{T}} L_{a,t}$, $I_t(\mathcal{L}_a) \triangleq \sum_{i=1}^{t} L_{a,i}$, $t \in \mathcal{T}$, $I_0(\mathcal{L}_a) \triangleq 0$, $\mathcal{T}(\mathcal{L}_a) \triangleq \{I_{t-1}(\mathcal{L}_a) + 1, I_{t-1}(\mathcal{L}_a) + 2, \ldots, I_t(\mathcal{L}_a)\}$, $t \in \mathcal{T}$, and $n \triangleq (n_1, n_2, \ldots, n_{L_a})$. Similarly, we can calculate the average load for the $L_a$ active users in $\mathcal{L}_a$ under given caching parameter $q$ and rewrite it
as:

\[ R_{\text{avg}}(\mathbf{L}_a, N, \mathbf{V}, \mathbf{q}) \triangleq \]

\[
\sum_{n \in \mathcal{N}} \left( \prod_{j=1}^{\mathbf{L}_a} p_{n_j} \right) \sum_{s=1}^{\mathbf{L}_a} \sum_{\mathcal{S} \subseteq \{1, \ldots, \mathbf{L}_a\} : |\mathcal{S}| = s} \max_{j \in \mathcal{S}} \left( \prod_{a \in \mathcal{S} \setminus \{j\}, t : a \in I_t(\mathbf{L}_a)} q_{t,n_j} \right) \left( \prod_{b \in \{1, \ldots, \mathbf{L}_a\} \setminus \mathcal{S} \setminus \{j\}} \prod_{t : b \in I_t(\mathbf{L}_a)} (1 - q_{t,n_j}) \right) V_{n_j}.
\]

We wish to optimize the caching parameter to minimize the worst-case load and average load of the shared link, both depending on \( \mathbf{L}_a \). As \( \mathbf{L}_a \) is unknown in the placement phase in a decentralized setting, we consider a carefully chosen substitute \( \mathbf{K} \triangleq (K_t)_{t \in \mathcal{T}} \) for \( \mathbf{L}_a \) based on some prior information. This parameter is referred to as the optimization parameter when formulating coded caching design optimization problems. For example, optimization parameter \( \mathbf{K} \) can be chosen as \( K_t = \lceil \mathbb{E}[L_{a,t}] \rceil \), \( t \in \mathcal{T} \), assuming that \( \mathbf{L}_a \) is random and the distribution is known. Please note that the proposed optimization framework in this paper successfully extends the parameter-based optimization framework in our previous work [2] which is for centralized coded caching in the scenario with the same file size and cache size. In addition, it is worth noting that the optimization-based frameworks for designing decentralized coded caching in [6], [8], [11] rely on the exact number of active users in the delivery phase, and hence cannot be directly applied to a decentralized setup. This problem can be appropriately handled by using a substitute for the exact number of active users in the delivery phase, as discussed above.

### IV. Worst-case Load Minimization

In this section, we first formulate a parameter-based coded caching design optimization problem over the considered class of schemes to minimize the worst-case load by optimizing the caching parameter. Next, we develop an iterative algorithm to obtain a stationary point of an equivalent problem. Finally, we obtain an approximate solution with low computational complexity and small worst-case load, and characterize its performance loss. To the best of our knowledge, this is the first work obtaining optimization-based decentralized coded caching design to reduce the worst-case load in the general scenario with arbitrary file sizes and cache sizes.
A. Problem Formulation

As the caching parameter $q$ fundamentally affects the worst-case load, we would like to optimize $q$ subject to the constraints in (3) and (4) so as to minimize $R_{wst}(K,N,V,q)$.

**Problem 1 (Caching Parameter Optimization for Reducing Worst-case Load):**

$$R^*_{wst}(K,N,V) \triangleq \min_q R_{wst}(K,N,V,q)$$

s.t. (3), (4),

where $R_{wst}(K,N,V,q)$ is given in (6).

As the objective function of Problem 1 is nonconvex and nondifferentiable, Problem 1 is a challenging problem. A classical goal for solving a nonconvex problem is to obtain a stationary point.

B. Solutions

1) Stationary Point: First, we obtain an equivalent nonconvex problem of Problem 1.

**Problem 2 (Equivalent Complementary GP of Problem 1):**

$$\min_{q,x,w>0,u>0} u$$

s.t. $\sum_{n=1}^{N} q_{t,n} V_n \bar{M}_t^{-1} \leq 1, \quad \forall t \in T,$

$$q_{t,n} \leq 1, \quad \forall t \in T, \quad n \in \mathcal{N},$$

$$\frac{1}{q_{t,n} + x_{t,n}} \leq 1, \quad \forall t \in T, \quad n \in \mathcal{N},$$

$$\prod_{a \in \mathcal{S} \setminus \{j\}} \prod_{t : a \in \mathcal{I}_t(K)} q_{t,n_j} \left( \prod_{b \in \mathcal{K} \setminus (\mathcal{S} \setminus \{j\}) \setminus \mathcal{S} \setminus \{j\}} \prod_{t : b \in \mathcal{I}_t(K)} x_{t,n_j} \right) V_{n_j} w_{n,S}^{-1} \leq 1,$$

$$\forall n \in \mathcal{N}^K, \quad \mathcal{S} \subseteq \mathcal{K} : |\mathcal{S}| = s, \quad j \in \mathcal{S},$$

$$\sum_{s=1}^{K} \sum_{\mathcal{S} \subseteq \mathcal{K} : |\mathcal{S}| = s} w_{n,S} u^{-1} \leq 1, \quad \forall n \in \mathcal{N}^K,$$

where $x \triangleq (x_{t,n})_{t \in T, n \in \mathcal{N}}$, $w \triangleq (w_{n,S})_{n \in \mathcal{N}^K, \mathcal{S} \subseteq \mathcal{K}}$, $K \triangleq \sum_{t \in T} K_t$ and $\mathcal{K} \triangleq \{1,2,\ldots,K\}$.

Note that in this paper, $\succ$ and $\succeq$ represent componentwise inequalities. In addition, note that for ease of analysis, we consider $q, x, w > 0, u > 0$ instead of $q, x, w \succeq 0, u \geq 0$, which does not change the optimal value or affect the numerical solution.
Algorithm 2 Algorithm for Obtaining a Stationary Point of Problem 2

1: **Initialization**: choose any feasible point \((q^{(0)}, x^{(0)}, w^{(0)}, u^{(0)})\) and set \(i = 1\)

2: **repeat**

3: Compute \((q^{(i)}, x^{(i)}, w^{(i)}, u^{(i)})\) by solving Problem 3 using interior point methods

4: Set \(i = i + 1\)

5: **until** some convergence criterion is met

---

**Lemma 1 (Equivalence between Problem 1 and Problem 2):** The optimal values of Problem 1 and Problem 2 are the same.

**Proof:** Please refer to Appendix A. □

Note that Problem 2 minimizes a posynomial subject to upper bound inequality constraints on posynomials (i.e., (8), (9), (11) and (12)) and upper bound inequality constraints on the ratio between two posynomials (i.e., (10)), and hence is a Complementary GP (which is not a conventional GP). A stationary point of a Complementary GP can be obtained by solving a sequence of approximate GPs [18]. Specifically, at iteration \(i\), \((q^{(i)}, x^{(i)}, w^{(i)}, u^{(i)})\) is updated by solving the following approximate GP of Problem 2, which is parameterized by \((q^{(i-1)}, x^{(i-1)}, w^{(i-1)}, u^{(i-1)})\) obtained at iteration \(i - 1\).

**Problem 3 (Approximate GP of Problem 2 at Iteration i):**

\[
(q^{(i)}, x^{(i)}, w^{(i)}, u^{(i)}) \triangleq \arg \min_{q, x, w > 0, u > 0} \ u \\
\text{s.t.} \ (8), (9), (11), (12), \ \\
\frac{1}{(q^{(i-1)}_t + x^{(i-1)}_t)} \left( \frac{q^{(i-1)}_t}{q^{(i-1)}_t + x^{(i-1)}_t} \right)^{\alpha^{(i-1)}_{t,n}} \left( \frac{x^{(i-1)}_t}{q^{(i-1)}_t + x^{(i-1)}_t} \right)^{\beta^{(i-1)}_{t,n}} \leq 1, \ \forall t \in T, n \in N, \tag{13}
\]

where

\[
\alpha^{(i-1)}_{t,n} \triangleq \frac{q^{(i-1)}_{t,n}}{q^{(i-1)}_{t,n} + x^{(i-1)}_{t,n}}, \quad \beta^{(i-1)}_{t,n} \triangleq \frac{x^{(i-1)}_{t,n}}{q^{(i-1)}_{t,n} + x^{(i-1)}_{t,n}}.
\]

Problem 3 is a standard form GP, which can be readily converted into a convex problem and solved efficiently (e.g., using interior point methods) [19]. The details are summarized in Algorithm 2. By [20], we know that \((q^{(i)}, x^{(i)}, w^{(i)}, u^{(i)})\) is provably convergent to a stationary point of Problem 2, as \(i \to \infty\).
2) Low-complexity Approximate Solution: As the numbers of variables and constraints of Problem 3 are $O(N^K)$ and $O(N^K K)$, respectively, and Problem 3 is solved at each iteration, the computational complexity of Algorithm 2 is high for large $N$ or $K$. In this part, we aim at obtaining a low-complexity approximate solution of Problem 1 with small worst-case load, which is applicable especially for large $N$ or $K$.

First, we approximate Problem 1 with a nondifferentiable objective function by a problem with a differentiable objective function. The nondifferentiable max function can be bounded from above and below by the following differentiable functions:

\[
\max\{x_1, x_2, \ldots, x_n\} \leq \frac{\ln(e^{cx_1} + \cdots + e^{cx_n})}{c},
\]

\[
\max\{x_1, x_2, \ldots, x_n\} \geq \frac{\ln(e^{cx_1} + \cdots + e^{cx_n})}{c} - \frac{\ln(n)}{c},
\]

where $c \geq 1$. It is clear that the upper and lower bounds are asymptotically tight as $c \to \infty$, and the equality in (15) holds when $x_1 = \cdots = x_n$. In addition, the upper bound in (14) is tighter when the deviation of $x_1, \ldots, x_n$ is larger, and the lower bound in (15) is tighter when the deviation is smaller. By (14), we can obtain an upper bound of $R_{wst}(K, N, V, q)$, denoted by

\[
R_{wst}^{\text{up}}(K, N, V, q) \triangleq \frac{1}{c} \ln \left( \sum_{n \in \mathcal{N}^K} \exp \left( c \sum_{s=1}^{K} \sum_{S \subseteq K, |S|=s} \frac{1}{c} \ln \left( \sum_{j \in S} \exp \left( c \prod_{a \in S \backslash \{j\}} \prod_{t : a \in I_t(K)} q_{t,n} \right) \right) V_{n,j} \right) \right).
\]

Therefore, we can approximate Problem 1 by minimizing the upper bound in (16).

Problem 4 (Approximate Problem of Problem 1):

\[
P_{wst}^{\text{ub}*}(K, N, V) \triangleq \min_q P_{wst}^{\text{ub}}(K, N, V, q)
\]

s.t. (3), (4).

Let $q_{wst}^{\dagger}$ denote an optimal solution of Problem 4.

Problem 4 is a nonconvex problem with a differentiable objective function and linear constraint functions. A stationary point of Problem 4 can be obtained efficiently (e.g., using gradient projection methods [19]). As the numbers of variables and constraints are both $O(NK)$, which are much smaller than those of Problem 3, the computational complexity for obtaining a stationary
point of Problem 4 is much lower than the computational complexity of Algorithm 2. Note that we can run a gradient projection algorithm multiple times, each with a random initial point, and select the stationary point which achieves the minimum objective value for Problem 4. Extensive numerical results show that this selected stationary point of Problem 4 is usually an optimal solution of Problem 4.

Next, based on the upper and lower bounds in (14) and (15), we characterize the worst-case load increment caused by the approximation, defined as \( L_{wst}(K, N, V) \equiv R_{wst}(K, N, V, q_{wst}^\dagger) - R^*_wst(K, N, V) \), where \( q_{wst}^\dagger \) is an optimal solution of Problem 4.

**Theorem 1 (Worst-case Load Increment):** For all \( c \geq 1 \),

\[
L_{wst}(K, N, V) \leq \frac{1}{c} \left( \sum_{i=1}^{K} \binom{K}{i} \ln i + K \ln N \right),
\]

\[
L_{wst}(K, N, V) = \frac{1}{c} O(2^K \ln K + K \ln N), \text{ as } K, N \to \infty.
\]

**Proof:** Please refer to Appendix B.

From Theorem 1, we know that the worst-case load increment can be made arbitrarily small by choosing a sufficiently large \( c \), for any fixed \( N \) and \( K \). However, in numerical experiments, the value of \( c \) has to be kept modest in order not to exceed the maximum allowed value. In addition, for all \( c \geq 1 \), the upper bound on the worst-case load increment increases with \( N \) and \( K \). Whereas, it will be seen in Section VII that the worst-case load of the low-complexity approximate solution is still very promising for large \( N \) or \( K \).

V. AVERAGE LOAD MINIMIZATION

In this section, we first formulate a parameter-based coded caching design optimization problem over the considered class of schemes to minimize the average load by optimizing the caching parameter. Then, we obtain a stationary point of an equivalent problem and a low-complexity approximate solution, using methods similar to those in Section IV for the worst-case load minimization. We present the main results for completeness. To the best of our knowledge, this is the first time that optimization-based decentralized coded caching design is obtained for reducing the average load in the general scenario with arbitrary file sizes and cache sizes.
A. Problem Formulation

We would like to optimize $q$ subject to the constraints in (3) and (4) so as to minimize $R_{\text{avg}}(K, N, V, q)$.

**Problem 5 (Caching Parameter Optimization for Reducing Average Load):**

$$R^*_{\text{avg}}(K, N, V) \triangleq \min_{q} R_{\text{avg}}(K, N, V, q)$$

s.t. (3), (4),

where $R_{\text{avg}}(K, N, V, q)$ is given in (7).

Problem 5 is a challenging problem due to the nonconvexity and nondifferentiability of the objective function.

B. Solutions

1) Stationary Point: First, we obtain an equivalent nonconvex problem of Problem 5 using a method similar to the one in Section IV-B1.

**Problem 6 (Equivalent Complementary GP of Problem 5):**

$$\min_{q, x, w > 0} \sum_{n \in \mathcal{N}} \left( \prod_{j=1}^{K} p_{n_j} \right) \sum_{j=1}^{K} \sum_{S \subseteq \mathcal{K} : |S| = s} w_{n, S}$$

s.t. (8), (9), (10), (11). (19)

**Lemma 2 (Equivalence between Problem 5 and Problem 6):** The optimal values of Problem 5 and Problem 6 are the same.

**Proof:** The proof is similar to that of Lemma 1 and is omitted due to page limitation.

It is clear that Problem 6 is a Complementary GP. We can obtain a stationary point by solving a sequence of approximate GPs [18]. Specifically, at iteration $i$, $(q^{(i)}, x^{(i)}, w^{(i)})$ is updated by solving the following approximate GP of Problem 6, which is parameterized by $(q^{(i-1)}, x^{(i-1)}, w^{(i-1)})$ obtained at iteration $i - 1$.

**Problem 7 (Approximate GP of Problem 6 at Iteration i):**

$$\left( q^{(i)}, x^{(i)}, w^{(i)} \right) \triangleq \arg \min_{q, x, w > 0} \sum_{n \in \mathcal{N}} \left( \prod_{j=1}^{K} p_{n_j} \right) \sum_{j=1}^{K} \sum_{S \subseteq \mathcal{K} : |S| = s} w_{n, S}$$

s.t. (8), (9), (11), (13).
Algorithm 3 Algorithm for Obtaining a Stationary Point of Problem 6

1: Initialization: choose any feasible point \((q^{(0)}, x^{(0)}, w^{(0)})\) and set \(i = 1\)
2: repeat
   3: Compute \((q^{(i)}, x^{(i)}, w^{(i)})\) by solving Problem 7 using interior point methods
   4: Set \(i = i + 1\)
5: until some convergence criterion is met

The details are summarized in Algorithm 3. By [20], we know that \((q^{(i)}, x^{(i)}, w^{(i)})\) is provably convergent to a stationary point of Problem 6, as \(i \to \infty\).

2) Low-complexity Approximate Solution: As the numbers of variables and constraints of Problem 7 are \(O(N^K)\) and \(O(N^K K')\), respectively, and Problem 7 is solved at each iteration, the computational complexity of Algorithm 3 is high for large \(N\) or \(K\). In this part, we obtain a low-complexity approximate solution of Problem 5, which is applicable especially for large \(N\) or \(K\).

First, we approximate Problem 5 which has a nondifferentiable objective function \(R_{\text{avg}}(K, N, V, q)\) by a problem whose objective function is a differentiable upper bound of \(R_{\text{avg}}(K, N, V, q)\), given by

\[
P_{\text{avg}}^{\text{ub}}(K, N, V, q) \triangleq \sum_{n \in K^K} \left( \prod_{j=1}^{K} p_{n_j} \right) \sum_{s=1}^{K} \sum_{S \subseteq K : |S| = s} \frac{1}{c} \ln \left( \sum_{j \in S} \exp \left( c \left( \prod_{a \in S \setminus \{j\}} \prod_{t : a \in I_t(K)} q_{t,n_j} \right) \right) \right)
\times \left( \prod_{b \in K \setminus (S\{j\})} \prod_{t : b \in I_t(K)} (1 - q_{t,n_j}) \right) V_{n_j}.
\]  

(20)

Problem 8 (Approximate Problem of Problem 5):

\[
P_{\text{avg}}^{\text{ub}*}(K, N, M) \triangleq \min_{q} P_{\text{avg}}^{\text{ub}}(K, N, V, q)
\]

s.t. \((3), (4)\).

Let \(q_{\text{avg}}^{\dagger}\) denote an optimal solution of Problem 8.

The numbers of variables and constraints of Problem 8 are both \(O(NK)\), which is much smaller than those of Problem 7. Thus, the computational complexity for obtaining a stationary point of Problem 8 (e.g., using gradient projection methods [19]) is much lower than that of Algorithm 3.
Next, we characterize the average load increment caused by the approximation, defined as $L_{\text{avg}}(K, N, V) \triangleq R_{\text{avg}}(K, N, V, q_{\text{avg}}) - R_{\text{avg}}^*(K, N, V)$, where $q_{\text{avg}}$ is an optimal solution of Problem 8.

Theorem 2 (Average Load Increment): For all $c \geq 1$,

$$ L_{\text{avg}}(K, N, V, M) \leq \frac{1}{c} \sum_{i=1}^{K} \left( \frac{K}{i} \right) \ln i, $$

$$ L_{\text{avg}}(K, N, V, M) = \frac{1}{c} O(2^K \ln K), \text{ as } K, N \to \infty. $$

Proof: Please refer to Appendix C.

From Theorem 2, we know that the average load increment can be made arbitrarily small by choosing a sufficiently large $c$, for any fixed $N$ and $K$. It will be seen in Section VII that the average load of the low-complexity approximate solution is still very promising for large $N$ or $K$.

VI. CONVERSE BOUND

In this section, we present information-theoretic converse bounds on the minimum worst-case load and average load (under an arbitrary file popularity) in the general scenario, respectively. Both converse bounds belong to the second class of converse bounds stated in Section I (applicable to both uncoded placement and coded placement). To our knowledge, this is the first work providing information-theoretic converse bounds on the minimum worst-case load and average load in the general scenario.

Given $S \subseteq L$, $|S| = s$, let $M_{[S,1]} \leq M_{[S,2]} \leq \cdots \leq M_{[S,s-1]} \leq M_{[S,s]}$ be $M_l$, $l \in S$ arranged in increasing order, so that $M_{[S,i]}$ is the $i$-th smallest. Extending the proof for the converse bound on the minimum worst-case load in the scenario with the same file size and cache size in [17], we obtain a converse bound on that in the scenario with arbitrary file sizes and cache sizes.

Lemma 3 (Converse Bound on Worst-case Load): The minimum worst-case load $R_{\text{wat}}^*(\mathcal{L}_a, N, V, M)$ for the shared, error-free link caching network with active users in $\mathcal{L}_a$, library size $N \in \mathbb{N}$, file sizes $V$ and cache sizes $M$ satisfies

$$ R_{\text{wat}}^*(\mathcal{L}_a, N, V, M) \geq \max_{m \in \{1, \ldots, \min\{N, M\}\}} \left\{ \frac{m}{N} \sum_{i=1}^{N} V_i - \min \left\{ \sum_{l=1}^{m} \frac{\sum_{i=1}^{l} M_{[L,a,i]}}{N-l+1}, \frac{m}{N} \sum_{i=1}^{m} M_{[L,a,i]} \right\} \right\}. $$

(23)
Proof: Please refer to Appendix D.

It is clear that the converse bound on the minimum worst-case load for arbitrary file sizes and cache sizes reduces to the one in [17] when $V_n, n \in \mathcal{N}$ are the same and $M_l, l \in \mathcal{L}_a$ are the same.

In addition, extending the proof for the converse bound on the minimum average load in the scenario with the same file size and cache size in [2], which rests on the genie-aided approach in [6] and the proof of Theorem 3 in [17], we have the following result.

**Lemma 4 (Converse Bound on Average Load):** The minimum average load $R^*_\text{avg}(\mathcal{L}_a, N, V, M)$ for the shared, error-free link caching network with active users in $\mathcal{L}_a$, library size $N \in \mathbb{N}$, file sizes $V$ and cache sizes $M$ under arbitrary file popularity distribution $p$ satisfies

$$R^*_\text{avg}(\mathcal{L}_a, N, V, M) \geq \max_{N' \in \{1, \ldots, N\}} \sum_{i=1}^{\mathcal{L}_a} \left( N' p_{N'} \right)^i \left( 1 - N' p_{N'} \right)^{\mathcal{L}_a-i} \sum_{S \subseteq \mathcal{L}_a : |S| = i} R^\text{lb, unif}_{\text{avg}}(S, N', V, M),$$

where

$$R^\text{lb, unif}_{\text{avg}}(S, N', V, M) \triangleq \max_{m \in \{1, \ldots, \min\{N', \mathcal{L}_a\}\}} \left\{ \sum_{j=1}^{m} \binom{N'-1}{j-1} \binom{m}{j} \sum_{i=1}^{N'} V_i - \min \left\{ \sum_{l=1}^{m} \sum_{i=1}^{f} M_{[S,i]} N', \left( 1 - \left( 1 - \frac{1}{N'} \right)^m \right) \sum_{i=1}^{m} M_{[S,i]} \right\} \right\}.$$  

(24)

Here $\{ \binom{m}{j} \}$ denotes the Stirling number of the second kind.

Proof: Please refer to Appendix E.

In Lemma 4, $R^\text{lb, unif}_{\text{avg}}(\mathcal{L}_a, N, V, M)$ and $R^\text{lb, unif}_{\text{avg}}(\mathcal{L}_a, N, V, M)$ represent the converse bounds on the average load under an arbitrary file popularity and the uniform file popularity, respectively. It is clear that the converse bound on the minimum average load for arbitrary file sizes and cache sizes under an arbitrary file popularity reduces to the one in [2] when $V_n, n \in \mathcal{N}$ are the same and $M_l, l \in \mathcal{L}_a$ are the same, and reduces to the one in [17] when $V_n, n \in \mathcal{N}$ are the same, $M_l, l \in \mathcal{L}_a$ are the same and the file popularity is uniform.

**VII. Numerical Results**

In this section, we compare the proposed solutions in Section IV and Section V with the existing ones [4]–[11] and the derived converse bounds in Section VI. As the computational complexities for the proposed stationary points are high for large $N$ or $K$, their performances
are evaluated only at $N \leq 4$ or $K \leq 4$. When obtaining the low-complexity approximate solutions, we choose $c = 1$. In addition, we adopt the existing solutions in [4]–[9] under the file size $\max_{n \in N} \{V_n\}$, and the existing solutions in [4]–[8], [10], [11] under the cache size $\min_{t \in T} \{M_t\}$, as they are originally proposed for the scenarios with the same file size ($V_n, n \in N$ are the same) and the same cache size ($M_t, t \in T$ are the same), respectively.

In the simulation, for ease of illustration, we assume file sizes (in $10^3$ data units) and cache sizes (in $10^3$ data units) are arithmetic sequences, i.e., $V_n = V_1 + (n - 1)\Delta V, n \in N$ and $M_t = M_1 + (k - 1)\Delta M, t \in T$, where $\Delta V$ and $\Delta M$ represent the common differences of the two sequences, respectively. In addition, in the average case, we assume that the file popularity follows Zipf distribution, i.e., $p_n = \frac{n^{-\gamma}}{\sum_{n \in N} n^{-\gamma}}$ for all $n \in N$, where $\gamma$ is the Zipf parameter [5]–[8]. We also consider different choices for parameter $K$ for the proposed solutions and those in [6], [8] and [11].

A. Comparison of Worst-case Loads

In this part, we compare the worst-case loads of the proposed stationary point and low-complexity approximate solution in Section IV with those of the existing solutions in [4], [9]–[11] and the converse bound in Lemma 3.

Fig. 2 (a) and Fig. 2 (b) illustrate the worst-case loads of the six schemes versus $N$ and $T$ (which is the same as $K$ in Fig. 2), respectively. From Fig. 2, we can see that the performance
Fig. 3: Worst-case load versus $\Delta V$ and $\Delta M$ when $N = 50$, $T = 4$, $L_a = (L_{a,t})_{t \in T}$ with $L_{a,t} = 1$, $t \in T$ and $K = L_a$.

(a) $V_1 = 25.5 - 24.5\Delta V$, $M_1 = 140$ and $\Delta M = 120$.

(b) $V_1 = 1$, $\Delta V = 1$ and $M_1 = 318.75 - 1.5\Delta M$.

Fig. 4: Worst-case load versus cache size parameter $\overline{M}_0$.

(a) $N = 50$, $V_1 = 1$, $\Delta V = 1$, $T = 4$, $M_1 = 80\overline{M}_0$, $\Delta M = 160\overline{M}_0$, $L_a = (L_{a,t})_{t \in T}$ with $L_{a,t} = 1$, $t \in T$ and $K = L_a$.

(b) $N = 10$, $V_1 = 10$, $\Delta V = -1$, $T = 2$, $M_1 = 5\overline{M}_0$, $\overline{M}_2 = 20\overline{M}_0$, $L_1 = 4$, $L_2 = 2$ and $K = (K_t)_{t \in T}$ with $K_t = 0.5L_2$, $t \in T$. Note that we assume that each user is active with probability 0.5, and show the average (over random $L_a$) of the worst-case load of each scheme and the average of the converse bound in Lemma 3.

gap between the proposed stationary point and low-complexity approximate solution is rather small, which shows a promising prospect of our low-complexity approximate solution.

Fig. 3 (a) and Fig. 3 (b) illustrate the worst-case loads of the proposed low-complexity approximate solution and the four baseline schemes versus $\Delta V$ and $\Delta M$, respectively. From Fig. 3, we can see that the worst-case load of the decentralized coded caching scheme in [4]
increases rapidly with both $\Delta V$ and $\Delta \overline{M}$. The worst-case load of the decentralized coded caching scheme in [9] increases rapidly with $\Delta V$, but increases slowly with $\Delta \overline{M}$. In contrast, the worst-case loads of the decentralized coded caching schemes in [10] and [11] increase slowly with $\Delta V$, but increase rapidly with $\Delta \overline{M}$. Note that the worst-case load of the proposed low-complexity approximate solution increases slowly with both $\Delta V$ and $\Delta \overline{M}$, indicating that it well adapts to the changes of file sizes and cache sizes.

Fig. 4 (a) and Fig. 4 (b) illustrate the worst-case loads of the proposed low-complexity approximate solution and the four baseline schemes, and the converse bound in Lemma 3 versus $\overline{M}_0$, which determines $(\overline{M}_t)_{t \in \mathcal{T}}$ as illustrated in the caption of Fig. 4. From Fig. 4, we can see that the worst-case load of the low-complexity approximate solution is close to the converse bound in Lemma 3, implying that it is close to optimal.

From Fig. 2, Fig. 3 and Fig. 4, we can see that, the two proposed solutions outperform the four baseline schemes in [4], [9]–[11] at the system parameters considered in the simulation. Their gains over the one in [4] are due to the adaptation to arbitrary file sizes and cache sizes; their gains over the one in [9] follow by the consideration of arbitrary file sizes; and their gains over the schemes in [10] and [11] follow by the consideration of arbitrary cache sizes.
B. Comparison of Average Loads

In this part, we compare the average loads of the proposed stationary points and low-complexity approximate solution in Section V with the existing solutions in [5]–[8] and the converse bound in Lemma 4. Fig. 5 (a) and Fig. 5 (b) illustrate the average loads of the six schemes versus $N$ and $T$ (which is the same as $K$ in Fig. 5), respectively. Fig. 6 (a) and Fig. 6 (b) illustrate the average loads of the proposed low-complexity approximate solution and the four baseline schemes versus $\Delta V$ and $\Delta M$, respectively. Fig. 8 (a) and Fig. 8 (b) illustrate the average loads of the proposed
low-complexity approximate solution and the four baseline schemes, and the converse bound in Lemma 4 versus cache size parameter $M_0$, which determines $(M_t)_{t \in T}$ as illustrated in the caption of Fig. 8. Similar observations can be made from Fig. 2, Fig. 3 and Fig. 4. Note that the average loads of the existing solutions in [5]–[7] do not change smoothly with some system parameters, as their design parameters are heuristically chosen. Fig. 7 illustrates the average loads of the proposed low-complexity approximate solution and the four baseline schemes versus $\gamma$. From Fig. 7, we can see that among all values of $\gamma$ considered in the simulation, the average load of the proposed low-complexity approximate solution is smaller than those of the decentralized coded caching schemes in [5]–[8], indicating that it well adapts to the changes of file popularity.

From Fig. 5, Fig. 6, Fig. 7 and Fig. 8, we can see that, the two proposed solutions outperform the four baseline schemes in [5]–[8] at the system parameters considered in the simulation, owing to their adaptions to file sizes and cache sizes.

VIII. CONCLUSION

In this paper, we proposed an optimization framework for decentralized coded caching in the general scenario with arbitrary file sizes and cache sizes to minimize the worst-case load and
average load. Specifically, we first proposed a class of decentralized coded caching schemes which are specified by a general caching parameter and include several known schemes as special cases. Then, we formulated two coded caching design optimization problems over the considered class of schemes to minimize the worst-case load and average load, respectively, with respect to the caching parameter. For each challenging nonconvex optimization problem, we developed an iterative algorithm to obtain a stationary point and proposed a low-complexity approximate solution with performance guarantee. In addition, we presented two information-theoretic converse bounds on the worst-case load and average load (under an arbitrary file popularity) in the general scenario, respectively. To the best of our knowledge, this is the first work that provides optimization-based decentralized coded caching schemes and information-theoretic converse bounds in the general scenario. Finally, numerical results showed that the proposed solutions outperform the existing schemes in the general scenario and highlighted the importance of designing optimization-based decentralized coded caching schemes for the general scenario.

APPENDIX A: PROOF OF LEMMA 1

First, for all \( t \in T \) and \( n \in N \), we introduce an auxiliary variable \( x_{t,n} \geq 0 \), replace \( 1 - q_{t,n} \) in \( R_{\text{wst}}(K, N, V, q) \) with \( x_{t,n} \), and add the inequality constraint
\[
1 - q_{t,n} \leq x_{t,n}, \quad \forall t \in T, \ n \in N.
\]
(26)

Next, for all \( n \in N^K \), \( S \subseteq K \), we introduce an auxiliary variable \( w_{n,S} \geq 0 \), replace
\[
\max_{n \in N^K} \left( \prod_{a \in S \setminus \{j\}} \prod_{t : a \in I_t(K)} q_{t,n_j} \right) \left( \prod_{b \notin K \setminus (S \setminus \{j\}) \setminus a \in I_t(K)} (1 - q_{t,n_j}) \right) V_{n_j}
\]
with \( w_{n,S} \), and add the inequality constraint
\[
\max_{n \in N^K} \left( \prod_{a \in S \setminus \{j\}} \prod_{t : a \in I_t(K)} q_{t,n_j} \right) \left( \prod_{b \notin K \setminus (S \setminus \{j\}) \setminus a \in I_t(K)} (1 - q_{t,n_j}) \right) V_{n_j} \leq w_{n,S}, \quad \forall n \in N^K, \ S \subseteq K.
\]
(27)

Finally, we introduce an auxiliary variable \( u \geq 0 \), replace \( \max_{n \in N^K} \sum_{s=1}^{K} \sum_{S \subseteq K : |S| = s} w_{n,S} \) with \( u \), and add the inequality constraint
\[
\max_{n \in N^K} \sum_{s=1}^{K} \sum_{S \subseteq K : |S| = s} w_{n,S} \leq u.
\]
(28)

Thus, we can equivalently convert Problem 1 to Problem 2. Therefore, we complete the proof.
APPENDIX B: PROOF OF THEOREM 1

We first prove (17). For notation simplicity, denote \( V_{n,S,j} \equiv \left( \prod_{a \in S \setminus \{j\}} \prod_{t:a \in I_t(K)} q_{t,n_j} \right) \times \left( \prod_{b \in K} (1 - q_{t,n_j}) \right) V_{n,j} \). By (6), we have

\[
R_{w^{st}}(K, N, V, q) \geq \max_{n \in \mathcal{N}} \sum_{s=1}^{K} \sum_{S \subseteq K, |S| = s} \left( \frac{1}{c} \ln \left( \sum_{j \in S} e^{V_{n,S,j}} \right) - \frac{1}{c} \ln s \right)
\]

\[
= \max_{n \in \mathcal{N}} \sum_{s=1}^{K} \sum_{S \subseteq K, |S| = s} \frac{1}{c} \ln \left( \sum_{j \in S} e^{V_{n,S,j}} \right) - \frac{1}{c} \ln s - \frac{1}{c} \ln N^K - \sum_{s=1}^{K} \sum_{S \subseteq K, |S| = s} \frac{1}{c} \ln s
\]

\[
= R_{w^{st}}^{ub}(K, N, V, q) - \frac{1}{c} \left( \sum_{s=1}^{K} \sum_{S \subseteq K, |S| = s} \ln s + K \ln N \right)
\]

\[
= R_{w^{st}}^{ub}(K, N, V, q) - \frac{1}{c} \left( \sum_{i=1}^{K} \binom{K}{i} \ln i + K \ln N \right) \equiv R_{w^{st}}^{ub}(K, N, V, q),
\]

where (a) and (b) are due to (15), and (c) is due to (16). Let \( q^*_{w^{st}} \) denote an optimal solution of Problem 1. We have

\[
L_{w^{st}}(K, N, V) = R_{w^{st}}(K, N, V, q^*_{w^{st}}) - R_{w^{st}}(K, N, V, q_{w^{st}})
\]

\[
\leq R_{w^{st}}^{ub}(K, N, V, q^*_{w^{st}}) - R_{w^{st}}(K, N, V, q_{w^{st}}) \leq R_{w^{st}}^{ub}(K, N, V, q^*_{w^{st}}) - R_{w^{st}}(K, N, V, q^*_{w^{st}})
\]

\[
\leq R_{w^{st}}^{ub}(K, N, V, q^*_{w^{st}}) - R_{w^{st}}^{ub}(K, N, V, q^*_{w^{st}}) \equiv \frac{1}{c} \left( \sum_{i=1}^{K} \binom{K}{i} \ln i + K \ln N \right),
\]

where (d) is due to (16), (e) is due to the optimality of \( q^*_{w^{st}} \) for Problem 4, and (f) and (g) are due to (29).

Next, we prove (18). Denote \( G_{w^{st}}(K, N) \equiv \frac{1}{c} \left( \sum_{i=1}^{K} \binom{K}{i} \ln i + K \ln N \right) \). We derive two upper bounds on \( G_{w^{st}}(K, N) \) as follows:

\[
G_{w^{st}}(K, N) \leq \frac{1}{c} \left( \sum_{i=1}^{K} \binom{K}{i} (i - 1) + K \ln N \right) \equiv \frac{1}{c} \left( K 2^{K-1} - 2^K + 1 + K \ln N \right),
\]

\[
G_{w^{st}}(K, N) \leq \frac{1}{c} \left( \sum_{i=1}^{K} \binom{K}{i} \ln K + K \ln N \right) = \frac{1}{c} \left( (2^K - 1) \ln K + K \ln N \right),
\]
where (h) is due to \( \ln x \leq x - 1 \), (i) is due to \( \sum_{i=1}^{K} i^2 = K^2 - 1 \), and (j) is due to \( \ln i \leq \ln K \), \( 1 \leq i \leq K \). By (30), (31) and (32), we have

\[
L_{\text{wst}}(K, N, V) \leq \min \left\{ \frac{1}{c} \left( K^2 - 1 - 2^K + 1 + K \ln N \right), \frac{1}{c} \left( (2^K - 1) \ln K + K \ln N \right) \right\}
\]

\[
= \frac{1}{c} \min \left\{ \left( \frac{K}{2} - 1 \right) 2^K + 1, (2^K - 1) \ln K \right\} + K \ln N = \frac{1}{c} O \left( 2^K \ln K + K \ln N \right).
\]

(33)

Thus, \( L_{\text{wst}}(K, N, V) = \frac{1}{c} O \left( 2^K \ln K + K \ln N \right) \).

Therefore, we complete the proof of Theorem 1.

**APPENDIX C: PROOF OF THEOREM 2**

We first prove (21). Similar to the proof for (29) in Appendix B, we have

\[
R_{\text{avg}}(K, N, V, q) \geq R_{\text{lb}}(K, N, V, q) = \frac{1}{c} \sum_{s=1}^{K} \left( \begin{array}{c} K \\ s \end{array} \right) \ln s \equiv R_{\text{lb}}(K, N, V, q).
\]

(34)

Let \( q_{\text{avg}} \) denote an optimal solution of Problem 5. Similar to the proof for (30) in Appendix B, we have

\[
L_{\text{avg}}(K, N, V) \leq R_{\text{avg}}(K, N, V, q_{\text{avg}}) - R_{\text{avg}}(K, N, V, q_{\text{avg}}) = \frac{1}{c} \sum_{i=1}^{K} \left( \begin{array}{c} K \\ i \end{array} \right) \ln i,
\]

(35)

where (a) is due to (34). Next, we prove (22). Similar to the proof for (33) in Appendix B, we have

\[
L_{\text{avg}}(K, N, V) \leq \min \left\{ \frac{1}{c} \left( K^2 - 1 - 2^K + 1 \right), \frac{1}{c} \left( (2^K - 1) \ln K \right) \right\}
\]

\[
= \frac{1}{c} \min \left\{ \left( \frac{K}{2} - 1 \right) 2^K + 1, (2^K - 1) \ln K \right\} = \frac{1}{c} O \left( 2^K \ln K \right).
\]

(36)

Thus, \( L_{\text{avg}}(K, N, V) = \frac{1}{c} O \left( 2^K \ln K \right) \). Therefore, we complete the proof of Theorem 2.

**APPENDIX D: PROOF OF LEMMA 3**

For notation simplicity, we assume that \( \mathcal{L}_a = \{1, 2, \ldots, L_a\} \) and \( M_1 \leq M_2 \leq \cdots \leq M_{L_a} \)

(i.e., \( M_{[\mathcal{L}_a, i]} = M_i, 1 \leq i \leq L_a \)) in the proof. By the proof of Lemma 1 in [17], for any \( m \in \{1, \ldots, \min \{L_a, N\}\} \), we have

\[
R(\mathcal{L}_a, N, V, M, d_a) \geq \sum_{i=1}^{m} H(W_{d_i}) \cdot \mathbb{1}\{d_i \notin \{d_1, \ldots, d_{i-1}\}\}
\]

\[
- \sum_{i=1}^{m} I(W_{d_i}; Z_1, \ldots, Z_i|W_{d_1}, \ldots, W_{d_{i-1}}),
\]

(37)
where \( \mathbb{1}\{d_l \notin \{d_1, \ldots, d_{l-1}\}\} \) denotes the indicator function that is 1 if \( d_l \) is not in \( \{d_1, \ldots, d_{l-1}\} \) and is 0 otherwise. Let \( Q_{m}^{\text{dist}} \) denote the set of all ordered \( m \)-dimensional demand vectors \((d_1, \ldots, d_m)\) with all distinct entries. Hence, \( |Q_{m}^{\text{dist}}| = \binom{N}{m}m! \). Averaging (37) over all demand vectors \( d \in Q_{m}^{\text{dist}} \) yields:

\[
R^*_\text{wat}(\mathcal{L}_a, \mathcal{N}, \mathbf{V}, \mathbf{M}) \geq \frac{1}{\binom{N}{m}m!} \sum_{d \in Q_{m}^{\text{dist}}} \sum_{l=1}^{m} H(W_{d_l}) \cdot \mathbb{1}\{d_l \notin \{d_1, \ldots, d_{l-1}\}\} - \sum_{l=1}^{m} \alpha_l, \quad (38)
\]

where \( \alpha_l \triangleq \frac{1}{\binom{N}{m}m!} \sum_{d \in Q_{m}^{\text{dist}}} I(W_{d_l}; Z_1) \), and \( \alpha_l \triangleq \frac{1}{\binom{N}{m}m!} \sum_{d \in Q_{m}^{\text{dist}}} I(W_{d_l}; Z_1, \ldots, Z_l|W_{d_1}, \ldots, W_{d_{l-1}}) \), \( l = 2, \ldots, m \). In the following, we derive an lower bound of the lower bound in (38) by analyzing its two terms, respectively. First, we simplify the first term of the lower bound in (38) as follows:

\[
= \frac{1}{\binom{N}{m}m!} \sum_{d \in Q_{m}^{\text{dist}}} \sum_{l=1}^{m} H(W_{d_l}) \cdot \mathbb{1}\{d_l \notin \{d_1, \ldots, d_{l-1}\}\} = \frac{1}{\binom{N}{m}m!} \sum_{S \subseteq \mathcal{N}^l, |S| = m} \sum_{i=1}^{N} V_i \quad (39)
\]

Next, we derive an upper bound of the second term of the lower bound in (38). For all \( 1 \leq l \leq m \), let \( \tilde{d} \triangleq (d_1, \ldots, d_{l-1}) \) and \( W_{\tilde{d}} \triangleq \{W_{d_1}, \ldots, W_{d_{l-1}}\} \). By the definition of \( \alpha_l \), \( 2 \leq l \leq m \), we have

\[
\alpha_l \overset{(a)}{\leq} \frac{1}{l!\binom{N}{l}} \sum_{d \in Q_{m-1}^{\text{dist}}} I(\{W_j : j \in \mathcal{N}\setminus\tilde{d}\}; Z_1, \ldots, Z_l|W_{\tilde{d}}) \overset{(b)}{\leq} \frac{1}{l!\binom{N}{l}} \sum_{d \in Q_{m-1}^{\text{dist}}} \sum_{i=1}^{l} M_i = \frac{\sum_{i=1}^{l} M_i}{N - l + 1},
\]

where (a) is due to (88) in the proof of Lemma 3 in [17] and (b) is due to \( I(\{W_j : j \in \mathcal{N}\setminus\tilde{d}\}; Z_1, \ldots, Z_l|W_{\tilde{d}}) \leq \sum_{i=1}^{l} H(Z_i) \), \( \tilde{d} \in Q_{m-1}^{\text{dist}} \) and \( H(Z_i) \leq M_i \), \( 1 \leq i \leq l \). Similarly, we have \( \alpha_1 \leq \frac{M_1}{N} \). Thus, we have

\[
\sum_{l=1}^{m} \alpha_l \leq \frac{1}{N - l + 1} \sum_{l=1}^{m} \sum_{i=1}^{l} M_i. \quad (40)
\]

In addition, by the definition of \( \alpha_l \), \( 1 \leq l \leq m \), we have

\[
\sum_{l=1}^{m} \alpha_l \leq m! \binom{N}{m} \sum_{l=1}^{m} \left( \frac{m}{N} \right) I(W_1, \ldots, W_N; Z_1, \ldots, Z_m) \overset{(d)}{\leq} m! \binom{N}{m} \sum_{i=1}^{m} M_i, \quad (41)
\]

where (c) is due to (91) in the proof of Lemma 3 in [17] and (d) is due to \( I(W_1, \ldots, W_N; Z_1, \ldots, Z_m) \leq \sum_{i=1}^{m} H(Z_i) \) and \( H(Z_i) \leq M_i \), \( 1 \leq i \leq m \). By (40) and (41), we have

\[
\sum_{l=1}^{m} \alpha_l \leq \min \left\{ \sum_{l=1}^{m} \frac{\sum_{i=1}^{l} M_i}{N - l + 1}, \frac{m}{N} \sum_{i=1}^{m} M_i \right\}. \quad (42)
\]

Finally, by (38), (39), (42) and optimizing over all possible choices of \( m \in \{1, \ldots, \min\{L_a, N\}\} \), we can show Lemma 3.
APPENDIX E: PROOF OF LEMMA 4

Let $R_{\text{avg,unif}}^*(S, N', V, M)$ denote the minimum average load of the shared link for the active users in $S$ when the library size is $N'$, file sizes are $(V_n)_{n=1}^{N'}$ and cache sizes are $M$ and the file popularity distribution follows the uniform distribution. Following the proof of Theorem 2 in [6], we have

$$R_{\text{avg,unif}}^*(L_a, N, V, M) \geq \max_{N' \in \{1, \ldots, N\}} \left\{ \sum_{i=1}^{L_a} \sum_{S \subseteq L_a, |S| = i} \left( N' p_{N'} \right)^i \left( 1 - N' p_{N'} \right)^{L_a-i} R_{\text{avg,unif}}^*(S, N', V, M) \right\}$$

$$= \max_{N' \in \{1, \ldots, N\}} \left\{ \sum_{i=1}^{L_a} \left( N' p_{N'} \right)^i \left( 1 - N' p_{N'} \right)^{L_a-i} \sum_{S \subseteq L_a, |S| = i} R_{\text{avg,unif}}^*(S, N', V, M) \right\} \quad (43)$$

Next, we derive a lower bound on $R_{\text{avg,unif}}^*(L_a, N, V, M)$. Without loss of generality, we assume that $L_a = \{1, 2, \ldots, L_a\}$ and $M_1 \leq M_2 \leq \cdots \leq M_{L_a}$ (i.e., $M_{[L_a,i]} = M_i, 1 \leq i \leq L_a$). Fix $m \in \{1, \ldots, \min\{L_a, N\}\}$. Let $Q_{\text{rep}}^m$ denote the set of all ordered $m$-dimensional demand vectors, where repetitions are allowed. Hence, $|Q_{\text{rep}}^m| = N^m$. Assume that the random requests of all $L_a$ users, i.e., $D_a \triangleq (D_1, \ldots, D_{L_a})$, follow the uniform distribution. Averaging (37) over all demand vectors $d \in Q_{\text{rep}}^m$ yields:

$$R_{\text{avg,unif}}^*(L_a, N, V, M) \geq \mathbb{E} \left[ \sum_{l=1}^{m} H(W_{D_l}) \cdot 1\{D_l \notin \{D_1, \ldots, D_{l-1}\}\} \right] - \sum_{l=1}^{m} \beta_l \quad (44)$$

where the expectation is with respect to $D_a$, $\beta_1 \triangleq I(W_{D_1}; Z_1|D_a)$ and $\beta_l \triangleq I(W_{D_l}; Z_1, \ldots, Z_l|W_{D_1}, \ldots, W_{D_{l-1}}, D_a), l = 2, \ldots, m$. In the following, we derive a lower bound of the lower bound on (44) by analyzing its two terms, respectively. First, we simplify the first term of the lower bound derived in (44) as follows:

$$\mathbb{E} \left[ \sum_{l=1}^{m} H(W_{D_l}) \cdot 1\{D_l \notin \{D_1, \ldots, D_{l-1}\}\} \right]$$

$$= \sum_{j=1}^{m} \sum_{S \subseteq N: |S| = j} \Pr \left( \sum_{l=1}^{j} H(W_{D_l}) \cdot 1\{D_l \notin \{D_1, \ldots, D_{l-1}\}\} = \sum_{i \in S} V_i \right) \sum_{i \in S} V_i$$

$$= \sum_{j=1}^{m} \sum_{S \subseteq N: |S| = j} j! \binom{m}{j} \binom{N}{j} \sum_{i \in S} V_i = \sum_{j=1}^{m} j! \binom{m}{j} \binom{N}{j} (N - 1)^{N-j-1} \sum_{i=1}^{N} V_i, \quad (45)$$
Next, we derive an upper bound on the second term of the lower bound derived in (44). By the definition of $\beta_l$, $2 \leq l \leq m$, we have

$$\beta_l \leq \frac{1}{N} \sum_{d \in \mathcal{Q}_{l-1}^{\text{rep}}} I(W_1, \ldots, W_N; Z_1, \ldots, Z_l|W_d) \leq \frac{1}{N} \sum_{i=1}^l M_i = \frac{\sum_{i=1}^l M_i}{N},$$

where (a) is due to (94) in the proof of Lemma 5 in [17] and (b) is due to $I(W_1, \ldots, W_N; Z_1, \ldots, Z_l|W_d) \leq \sum_{i=1}^l H(Z_i)$, $d \in \mathcal{Q}_{l-1}^{\text{rep}}$ and $H(Z_i) \leq M_i$, $1 \leq i \leq l$. Similarly, we have $\beta_1 \leq \frac{M_1}{N}$. Thus, we have

$$\sum_{l=1}^m \beta_l \leq \sum_{l=1}^m \frac{\sum_{i=1}^l M_i}{N}. \quad (46)$$

In addition, by the definition of $\beta_l$, $1 \leq l \leq m$,

$$\sum_{l=1}^m \beta_l \leq \sum_{i=1}^m \Pr\left(\kappa_{D_a}(m) = i\right) \frac{i}{N} I(W_1, \ldots, W_N; Z_1, \ldots, Z_m) \leq \sum_{i=1}^m \Pr\left(\kappa_{D_a}(m) = i\right) \cdot i \cdot \frac{\sum_{i=1}^m M_i}{N} = \mathbb{E}[\kappa_{D_a}(m)] \sum_{i=1}^m M_i, \quad (47)$$

where (c) is due to (96) in the proof of Lemma 5 in [17] and (d) is due to $I(W_1, \ldots, W_N; Z_1, \ldots, Z_m) \leq \sum_{i=1}^m H(Z_i)$ and $H(Z_i) \leq M_i$, $1 \leq i \leq m$. Here $\kappa_{D_a}(m)$ denotes the number of distinct demands for users $1, \ldots, m$. By (46) and (47), we have

$$\sum_{l=1}^m \beta_l \leq \min\left\{ \sum_{l=1}^m \frac{\sum_{i=1}^l M_i}{N}, \mathbb{E}[\kappa_{D_a}(m)] \sum_{i=1}^m M_i \right\}. \quad (48)$$

By Lemma 4 in [17], we have

$$\mathbb{E}[\kappa_{D_a}(m)] = N \left(1 - \left(1 - \frac{1}{N}\right)^m\right). \quad (49)$$

Finally, by (44), (45), (48), (49) and optimizing over all possible choices of $m \in \{1, \ldots, \min\{L_a, N\}\}$, we have

$$R_{\text{avg}, \text{unif}}^*(\mathcal{L}_a, N, V, M) \geq R_{\text{avg}, \text{unif}}^\text{lb}(\mathcal{L}_a, N, V, M). \quad (50)$$

Therefore, by (43) and (50), we can show Lemma 4.
