Improved bounds for sparse recovery from subsampled random convolutions

Shahar Mendelson*, Holger Rauhut†, Rachel Ward‡

October 17, 2016

Abstract

We study the recovery of sparse vectors from subsampled random convolutions via \( \ell_1 \)-minimization. We consider the setup in which both the subsampling locations as well as the generating vector are chosen at random. For a subgaussian generator with independent entries, we improve previously known estimates: if the sparsity \( s \) is small enough, i.e. \( s \lesssim \sqrt{n}/\log(n) \), we show that \( m \gtrsim s \log(en/s) \) measurements are sufficient to recover \( s \)-sparse vectors in dimension \( n \) with high probability, matching the well-known condition for recovery from standard Gaussian measurements. If \( s \) is larger, then essentially \( m \geq s \log^2(s) \log(\log(s)) \log(n) \) measurements are sufficient, again improving over previous estimates. Moreover, we also provide robustness estimates for measurement errors that are bounded in \( \ell_q \) for \( q > 2 \) – in particular, allowing the case \( q = \infty \) which is important for quantized compressive sensing. All these results are shown via \( \ell_q \)-robust versions of the null space property and for \( q > 2 \) they represent the first non-trivial bounds for structured random matrices. As a crucial ingredient, our approach requires to lower bound expressions of the form \( \inf_{v \in V_s} \| \Gamma_v \xi \|_q \), where \( \Gamma_v \) is a set of matrices indexed by unit norm \( r \)-sparse vectors and \( \xi \) is a subgaussian random vector. This involves the combination of small ball estimates with chaining techniques.

1 Introduction

Compressive sensing [6, 13, 17] considers the recovery of (approximately) sparse vectors from incomplete and possibly perturbed linear measurements via efficient algorithms such as \( \ell_1 \)-minimization. Provably optimal bounds for the minimal number of required measurements in terms of the sparsity have been shown for Gaussian and, more generally, subgaussian random matrices [4, 9, 13, 14, 17, 28, 29, 39].

Practical applications demand for structure in the measurement process which is clearly not present in Gaussian random matrices with independent entries. Several types of structured random matrices have been studied, including random partial Fourier matrices [6, 7, 39, 34, 37, 5], partial random circulant matrices (subsampled random convolutions) [24, 33, 34, 36, 38],
time-frequency structured random matrices [24, 35, 32], and more [2, 20]. In this article, we improve known recovery results for partial random circulant matrices.

In mathematical terms, linear measurements of a signal (vector) \( x \in \mathbb{R}^n \) can be written as

\[
y = Ax \quad \text{with} \quad A \in \mathbb{R}^{m \times n},
\]

and we are particularly interested in the case \( m < n \). Compressive sensing predicts that this system can be solved for \( x \) using efficient algorithms if \( x \) is sparse enough, say in the sense that \( \|x\|_0 = |\{\ell : x_\ell \neq 0\}| \) is small. While \( \ell_0 \)-minimization is NP-hard [17], several tractable algorithms have been introduced as alternatives, most notably \( \ell_1 \)-minimization (basis pursuit) [6, 10, 13, 17] which produces a minimizer of

\[
\min_{z \in \mathbb{R}^n} \|z\|_1 \quad \text{subject to} \quad Az = y.
\]

If \( A \in \mathbb{R}^{m \times n} \) is a random draw of a Gaussian matrix, i.e., all entries are standard normal random variables, then with probability at least \( 1 - e^{-cm} \), any \( s \)-sparse vector \( x \in \mathbb{R}^n \), (i.e., \( \|x\|_0 \leq s \)), can be reconstructed in a stable way (see below) using \( \ell_1 \)-minimization from the given data \( y = Ax \), provided that

\[
m \geq Cs \ln(en/s) \quad (1.1)
\]

for some absolute constant \( C > 0 \). This bound is optimal [13, 16, 17] in the sense that the combination of any recovery algorithm with any measurement matrix requires at least (1.1) many measurements in order to achieve stable reconstruction, i.e., for any \( x \in \mathbb{R}^n \) (not necessarily \( s \)-sparse), the reconstruction \( x^# \) obtained from \( y = Ax \), satisfies

\[
\|x - x^#\|_1 \leq C\sigma_s(x)_1 := C\inf\{\|x - z\|_1 : \|z\|_0 \leq s\}, \quad (1.2)
\]

see [16, Theorem 2.7] for details. Moreover, exact \( s \)-sparse recovery via \( \ell_1 \)-minimization necessarily requires (1.1), see [16, Lemma 2.4].

Unfortunately, Gaussian random matrices are not suitable for many applications of compressive sensing – because of their lack of structure. In fact, structure is required in order to model realistic measurement scenarios and also to speed up the matrix-vector-multiplications that have to be applied many times in known \( \ell_1 \)-minimization algorithms.

An important example of structured random matrices are \( m \times n \) matrices that are generated from the \( n \times n \) discrete Fourier (more generally, from a Hadamard type matrix, see Definition 2.6 below), by randomly subsampling \( m \) rows. This corresponds to taking \( m \) random samples of the discrete Fourier transform of a vector. Again, \( \ell_1 \)-minimization successfully recovers \( s \)-sparse vectors with probability at least \( 1 - \varepsilon \) provided that

\[
m \geq Cs \max\{\log^2(s) \log(n), \log(\varepsilon^{-1})\},
\]

see, for example, [7, 39, 34, 5, 19].

In this article we will be concerned with subsampled random convolutions. The circular convolution on \( \mathbb{R}^n \) is defined for two vectors \( x, \xi \in \mathbb{R}^n \) as

\[
(x * \xi)_k = \sum_{j=1}^{n} x_j \xi_{k-j \mod n+1}, \quad k = 1, \ldots, n.
\]
For a subset $\Omega \subset \{1, \ldots, n\} =: \lfloor n \rfloor$ of cardinality $m$, let $P_\Omega : \mathbb{R}^n \to \mathbb{R}^m$ be the projection onto the coordinates indexed by $\Omega$, i.e., $(P_\Omega x)_j = x_j$ for $j \in \Omega$. A subsampled convolution is defined as
\begin{equation}
Bx = P_\Omega (x * \xi) \tag{1.3}
\end{equation}
and the corresponding matrix is a partial circulant matrix generated by $\xi$. Subsampled random convolutions find applications in radar and coded aperture imaging [3, 18, 38, 42], as well as in fast dimensionality reduction maps [25].

It was shown in [24] that if $\xi$ is a (standard) Gaussian vector and $\Omega$ is an arbitrary (deterministic) subset of cardinality $m$, then with probability at least $1 - \varepsilon$, every $s$-sparse vector can be reconstructed from $Bx$ via $\ell_1$-minimization if
\begin{equation}
m \geq C s \max\{ \log^2(s) \log^2(n), \log(\varepsilon^{-1}) \}. \tag{1.4}
\end{equation}
Moreover, stability in the sense of (1.2) holds for such matrices, and the results are robust when the given measurements are corrupted by noise (see more details below). Moreover, the recovery result can be extended to circulant matrices generated by a subgaussian random vector – an object of central importance to our discussion which will be defined later.

Our focus is on sparse recovery via subsampled random convolutions, where the set $\Omega$ is chosen at random via independent selectors: let $(\delta_i)_{i=1}^n$ be independent, $\{0, 1\}$-valued random variables with mean $\delta = m/n \in (0, 1]$, and set $\Omega = \{i : \delta_i = 1\}$. Then the expected size of $\Omega$ is $E|\Omega| = m$ and it follows from Bernstein’s inequality that $m/2 \leq |\Omega| \leq 3m/2$ with probability at least $1 - 2 \exp(-m/9)$.

For the sake of simplicity of this exposition, we shall first formulate our main theorem for a standard Gaussian generator, i.e., a random vector with independent, mean zero, variance one, normally distributed coordinates. However, the proof we present holds for more general $L$-subgaussian random vectors with independent coordinates and a more general type of random matrices (see Theorem 2.5).

**Theorem 1.1** Let $\xi \in \mathbb{R}^n$ be a random draw of a standard Gaussian random vector and let $\Omega \subset \lfloor n \rfloor$ be chosen at random, using independent selectors of mean $\delta = m/n$. Let $B$ be the corresponding partial random circulant matrix defined in (1.3). Let $s \leq c_1 \frac{n}{\log(n)}$ and assume that
\begin{align*}
m &\geq c_3 s \log(en/s) & \text{if } s \leq c_2 \sqrt{\frac{n}{\log(n)}} \\
m &\geq c_3 s \log(en/s) \alpha_s^2 \log(\alpha_s) & \text{if } c_2 \sqrt{\frac{n}{\log(n)}} \leq s \leq c_1 \frac{n}{\log^3(n)}, \tag{1.5}
\end{align*}
where $\alpha_s = \log\left(\frac{s^2}{n} \max\{\log(en/s), \log(s)\}\right)$. Then with probability at least
\begin{equation}
1 - 2 \exp\left(-c_0 \min\left\{\frac{n}{s}, s \log(en/s)\right\}\right)
\end{equation}
the following holds. For all $x \in \mathbb{R}^n$, all $e \in \mathbb{R}^m$ with $\|e\|_2 \leq \eta$ and $y = Bx + e$, the minimizer $x^*$ of
\begin{equation}
\min \|z\|_1 \quad \text{subject to } \|Bz - y\|_2 \leq \eta \tag{1.6}
\end{equation}
satisfies

\[ \|x - x^\sharp\|_1 \leq C\sigma_s(x) + D\frac{\sqrt{s}\eta}{\sqrt{m}} \quad \text{and} \quad (1.7) \]

\[ \|x - x^\sharp\|_2 \leq C\frac{\sigma_s(x)}{\sqrt{s}} + D\frac{\eta}{\sqrt{m}} \quad (1.8) \]

Our estimates indicate a phase-transition that occurs when \( s \) is roughly of the order of \( \sqrt{n} \). Below this level, the partial circulant matrix exhibits the same behavior as the Gaussian matrix (which is the optimal scaling of the number of measurements \( m \) as a function of the sparsity parameter \( s \)) – it requires \( Cs\log(en/s) \) measurements to recover an \( s \)-sparse vector. Above that level, more measurements are required; for example, if \( s = n^\alpha \) for \( 1/2 < \alpha < 1 \) then \( c(L, \alpha)n^\alpha \log^3 n \cdot \log \log n \) measurements are needed.

As we will see later, the phase transition at \( \sqrt{n}/\log(n) \) is not a coincidence – the analysis required in the low-sparsity case is truly different from the one needed to deal with the high-sparsity one. However, it is presently not clear whether the analysis for the high-sparsity case can be improved in order to remove the additional logarithmic factors.

In both cases (low and high sparsity) we improve the estimates from [24], though it should be noted that (1.4) applies to any set \( \Omega \subset [n] \) of cardinality \( m \), while (1.5) applies only to randomly chosen \( \Omega \). A random selection \( \Omega \) has been considered in [38], but the estimates there require \( m \geq Cs\log^6(n) \). On the other hand, [38] applies to vectors that are sparse in an arbitrary (fixed) orthonormal basis and not only in the canonical basis; our proof technique does not seem to extend to this case in a simple way.

Moreover, we stress that (1.1) provides a uniform recovery guarantee in the sense that a single random draw of the partial circulant matrix is able to recovery all \( s \)-sparse vectors simultaneously. This is in contrast to other previous so-called nonuniform results found in the literature [33, 34, 21] that only imply recovery of a fixed sparse vector from a random draw of the matrix. Moreover, these nonuniform results give no or weaker stability estimates than (1.7) and (1.8), see e.g. [17, Theorem 4.33] or [15].

Another improvement on known estimates is that our results hold for noisy measurements when the noise is bounded in \( \ell_q \) for \( q \geq 2 \) and the \( \ell_2 \)-constraint in (1.6) is replaced by an \( \ell_q \)-constraint (and the error estimates scale with the \( \ell_q \) norm of the noise), see Theorem 6.1 for details. This allows us, for example, to explore quantized compressive sensing (see, e.g., [12]), when the quantization error has a natural \( \ell_\infty \)-bound. In contrast, all the recovery results mentioned above were derived via the restricted isometry property (RIP), and applying the RIP, knowing only that the noise is bounded in \( \ell_q \) for \( q > 2 \), leads to a poor scaling of the number of required measurements in terms of the degree of sparsity (see [12] for a detailed discussion on this issue). The reason why we can handle bounded noise in \( \ell_q \) for \( q > 2 \) is that the proof we present is not based on the (two-sided) RIP, but rather on suitable versions of the null-space property, which we define in the next section. Our new bound provides the first rigorous proof of the \( \ell_q \)-robust null space for structured random matrices for \( q > 2 \) with an optimal scaling of the number of measurements in the sparsity up to possibly logarithmic factors, see Theorem 6.1 for details.

We note that for a few other constructions of structured random matrices (with fast matrix-vector multiplication), recovery results with the optimal number of measurements (1.1) have
been shown under similar size restrictions on the sparsity as in our main theorem above [1, 2]. However, it seems that our construction is the simplest one and is arguably the only one among these which models a physically realizable measurement device. In contrast to these previous results, we are able to extend our bounds to the near-linear sparsity regime at the cost of some additional logarithmic factors.

Independently of our main results themselves, we believe that our proof techniques should be of interest as well. In fact, the crucial ingredient in our proof is a probabilistic lower bound on terms of the form \( \inf_{v \in V_r} \| \Gamma_v \xi \|_q \), where \( \Gamma_v \) are matrices indexed by a set of unit norm \( r \)-sparse vectors and \( \xi \) is subgaussian random vector with independent coordinates. We use a combination small ball estimates, covering number bounds and chaining techniques. We are not aware that our proof technique was used before in a similar way and context. We remark that our main ingredient can be generalized to random vectors with heavier tails and less independence assumptions, for instance, log-concave random vectors. Details will be presented in a future contribution.

The article is structured as follows. Section 2 discusses preliminaries such as the null space property, subgaussian random vectors, states the main result and gives a brief explanation of its proof. Section 3 introduces the small ball estimates required for the proof as well as moment estimates for norms of subgaussian random vectors. It further provides some covering number estimates required in the sequel. Section 4 provides the main technical ingredient of the proof of our main results which consists in a lower bound for \( \inf_{v \in V_r} \| \Gamma_v \xi \|_2 \). Section 5 provides an upper bound over the one-sparse vectors, which is required for completing the proof of the null space property, see also Theorem 2.3. Finally, Section 6 provides the extension of our recovery result to robustness in \( \ell_q \) for \( q > 2 \).

2 Preliminaries and main result

2.1 The null space property

Our analysis is based on a robust version of the null space property which is a sufficient and necessary condition for sparse recovery via \( \ell_1 \)-minimization. This version is stable when passing to approximately sparse vectors, and is robust when the measurements are noisy. We begin with several standard facts on this.

Given \( v \in \mathbb{R}^n \) and \( S \subset [n] = \{1, \ldots, n\} \), let \( v_S \in \mathbb{R}^n \) with entries \( (v_S)_j = v_j \) for \( j \in S \) and \( (v_S)_j = 0 \) for \( j \notin S \). Further, \( S^c = [n] \setminus S \) denotes the complement of \( S \).

Definition 2.1 For \( 1 \leq q \leq \infty \), a matrix \( A \) satisfies the \( \ell_q \)-robust null-space property of order \( s \) with constants \( \nu \in (0, 1) \) and \( \tau > 0 \) if

\[
\|v_S\|_2 \leq \frac{\nu}{\sqrt{s}} \|v_{S^c}\|_1 + \tau \|Av\|_q
\]
for every $v \in \mathbb{R}^n$ and every $S \subset [n]$ of cardinality at most $s$.

The following result is standard by now (see, e.g., [17, Theorem 4.22]). It uses the notion of the error of best $s$-term approximation, defined as

$$\sigma_s(x)_1 = \min_{z: \|z\|_0 \leq s} \|x - z\|_1;$$

that is, $\sigma_s(x)_1$ is the $\ell_1$ distance between $x$ and the set of $s$-sparse vectors.

**Theorem 2.2** Let $1 \leq q \leq \infty$ and let $A$ satisfy the $\ell_q$-robust null space property of order $s$ with constants $\nu \in (0, 1)$ and $\tau > 0$. Let $\|e\|_q \leq \eta$, $x \in \mathbb{R}^n$ and put $y = Ax + e$. Then a minimizer $x^\sharp$ of

$$\min_{z \in \mathbb{R}^n} \|z\|_1 \quad \text{subject to} \quad \|Az - y\|_q \leq \eta$$

satisfies

$$\|x - x^\sharp\|_1 \leq C\sigma_s(x)_1 + D\sqrt{s}\eta \quad (2.1)$$

$$\|x - x^\sharp\|_2 \leq \frac{C}{\sqrt{s}}\sigma_s(x)_1 + D\eta, \quad (2.2)$$

where the constants are given by $C = \frac{(1 + \nu)^2}{1 - \nu}$ and $D = \frac{(3 + \nu)}{1 - \nu}\tau$.

Roughly speaking, even if $x$ is not $s$-sparse, but only approximated by an $s$-sparse vector, and if one receives linear measurements of $x$ (i.e., $Ax$) that are corrupted by the “noise” $e$, then a solution to the minimization problem still yields a good approximation of $x$ if $A$ possesses the null space property. In particular, if $x$ is $s$-sparse then $\sigma_s(x)_1 = 0$, and if $\eta = 0$ (no noise), then the reconstruction via equality constrained $\ell_1$-minimization is exact.

In order to show the $\ell_q$-robust null-space property, we will proceed in the following way. Let

$$T_{\nu, s} := \left\{ v \in \mathbb{R}^n : \|v_S\|_2 \geq \nu \sqrt{s}\|v_{S^c}\|_1 \right\}.$$ 

One may show (see, e.g., [12, 22]) that if

$$\inf_{x \in T_{\nu, s} \cap \mathbb{S}^{n-1}} \|Ax\|_q \geq \frac{1}{\tau},$$

then $A$ satisfies the $\ell_q$-robust null space property with constants $\nu$ and $\tau$. Moreover, if we set

$$V_s = \{ x \in \mathbb{R}^n : \|x\|_0 \leq s, \|x\|_2 = 1 \}$$

to be the set of $s$-sparse vectors in the unit sphere, then ([22, Lemma 3], see also [39])

$$T_{\nu, s} \cap \mathbb{S}^{n-1} \subset (2 + \nu^{-1}) \text{conv } V_s,$$ \quad (2.3)

allowing one to study conv $V_s$ instead of $T_{\nu, s}$, where conv $S$ denotes the convex hull of the set $S$, that is, the set of all convex combinations of finite subsets of $S$.

It turns out that one may replace conv $V_s$ with $V_r$ for $r$ sufficiently large by adding a condition on one-sparse vectors. This was observed for $q = 2$ in [31, Lemma 5.1] (see also [26, Theorem B]). We will extend this result to $q \geq 2$ in Theorem 6.2, which however comes with worse constants for $q = 2$ than the statement below.
Theorem 2.3 Let \( A \in \mathbb{R}^{m \times n} \) satisfy
\[
\inf_{x \in V_r} \|Ax\|_2 \geq \tau^{-1} \quad \text{and} \quad \max_{j \leq [n]} \|Ae_j\|_2 \leq M.
\] (2.4)

If \( c(\nu) = \nu^2 / (2\nu + 1)^2 \) and
\[
s \leq c(\nu) \frac{r - 1}{M^2 \tau^2 - 1},
\]
then
\[
\inf_{x \in T_{\nu,s}} \|Ax\|_2 \geq \frac{1}{\sqrt{2} \tau}.
\]

Proof. By (2.3), it suffices to show that the conditions in (2.4) imply that
\[
\inf_{x \in (2 + \nu - 1) \text{conv} V_s \cap S^n - 1} \|Ax\|_2 \geq 1 / (\sqrt{2} \tau).
\]

Applying [26, Lemma 2.6] (see also the proof of Lemma 6.2 specialized to \( q = 2 \)), it follows from (2.4) that for any \( y \in \mathbb{R}^n \)
\[
\|Ay\|_2^2 \geq \tau^{-2} \|y\|_2^2 - \frac{1}{r - 1} \left( \|y\|_1 \sum_{j=1}^n \|Ae_j\|_2^2 |y_j| - \tau^{-2} \|y\|_1^2 \right).
\]

Let \( B_1^n \) be the unit ball in \( \ell_1^n \) and observe that \( \text{conv} V_s \subset \sqrt{s}B_1^n \). Thus, if \( c_1(\nu) = 2 + 1/\nu \) and \( y \in S^n - 1 \cap c_1(\nu) \text{ conv } V_s \),
\[
\|y\|_2 = 1 \quad \text{and} \quad \|y\|_1 \leq c_1(\nu) \sqrt{s}.
\]

Therefore,
\[
\|Ay\|_2^2 \geq \tau^{-2} \left( 1 - \frac{\|y\|_2^2}{r - 1} \left( \tau^2 \max_{1 \leq j \leq n} \|Ae_j\|_2 - 1 \right) \right) \geq \tau^{-2} \left( 1 - \frac{c_1^2(\nu) s}{r - 1} (\tau^2 M^2 - 1) \right) \geq \frac{1}{2\tau^2}
\]
by our choice of \( s \).

With Theorem 2.3 at hand, we will take the following course of action: we will show that
\[
\inf_{x \in V_r} \|P_\Omega Ax\|_2 \gtrsim \sqrt{m} \quad \text{and} \quad \max_{j \leq [n]} \|P_\Omega Ae_j\|_2 \lesssim \sqrt{m}
\] (2.5)
for a partial circulant matrix \( P_\Omega A \), whose rows are chosen using iid selectors.

2.2 Subgaussian random vectors

Just as in [24] we will focus on generators \( \xi \) that are isotropic, \( L \)-subgaussian and have independent coordinates.

Definition 2.4 A centered random vector \( \xi = (\xi_i)_{i=1}^n \) is \( L \)-subgaussian if for every \( x \in \mathbb{R}^n \),
\[
\|\langle \xi, x \rangle\|_{L_p} \leq L \sqrt{p} \|\langle \xi, x \rangle\|_{L_2}.
\]
Assume that $\xi_1, \ldots, \xi_n$ are independent, mean-zero, variance 1, $L$-subgaussian random variables. In other words, for every $p \geq 1$,

$$\|\xi_i\|_{L^p} \leq L\sqrt{p}\|\xi_i\|_{L^2} = L\sqrt{p}.$$ 

Then $\xi$ is an isotropic random vector on $\mathbb{R}^n$: for every $x \in \mathbb{R}^n$, $E \langle \xi, x \rangle^2 = \|x\|_2^2$, and it is standard to verify that it is $L$-subgaussian as well (see, e.g., [43]). Is it straightforward to show that if $\xi$ is an $L$-subgaussian random vector, then for every $x \in \mathbb{R}^n$ and $u \geq 1$,

$$Pr \left( |\langle \xi, x \rangle| \geq uL\|\langle \xi, x \rangle\|_{L^2} \right) \leq 2 \exp(-cu^2),$$

for a suitable absolute constant $c$. If, in addition, $\xi$ is isotropic, then

$$Pr \left( |\langle \xi, x \rangle| \geq uL\|x\|_2 \right) \leq 2 \exp(-cu^2).$$

### 2.3 Main result

Our main result provides a bound for the null-space property of partial random circulant matrices. It implies Theorem 1.1 via Theorem 2.2.

Recall that

- $\xi$ is a random vector whose coordinates are independent, mean-zero, variance 1, $L$-subgaussian random variables;
- $A$ is the complete circulant matrix generated by $\xi$;
- $(\delta_i)_{i=1}^n$ are independent selectors of mean $\delta = m/n$, and $\Omega = \{i : \delta_i = 1\}$.

**Theorem 2.5** There exist constants $c_0, \ldots, c_6$ that depend only on $L$, $\rho$ and $\tau$ for which the following holds. With probability at least

$$1 - 2 \exp \left( -c_0 \min \left\{ \frac{n}{\rho}, r \log \left( \frac{en}{r} \right) \right\} \right),$$

the partial circulant matrix $P_{\Omega}A$ satisfies the $\ell_2$-robust null-space property of order $r$ with constants $\rho \in (0, 1)$ and $\tau/\sqrt{m}$, where

$$\delta n = c_3 r \log \left( \frac{en}{r} \right) \quad \text{if} \quad r \leq c_4 \sqrt{\frac{n}{\log n}},$$

and

$$\delta n = c_3 r \log \left( \frac{en}{r} \right) \cdot \alpha_r^2 \log \alpha_r \quad \text{if} \quad c_4 \sqrt{\frac{n}{\log n}} < r \leq c_5 \frac{n}{\log^4 n}.$$ 

The constant $\alpha_r$ satisfies

$$\alpha_r \leq \log \left( c_6 \frac{r^2}{n} \max \left\{ \log \left( \frac{en}{r} \right), \log(e^r) \right\} \right).$$

The result will actually be shown for a more general class of random matrices, see Definition (2.6) and the remarks following it.
2.4 The heart of the argument

The proof of Theorem 2.5 has two main components. We will begin by analyzing the way a complete circulant matrix $A : \mathbb{R}^n \rightarrow \mathbb{R}^n$ generated by $\xi$ acts on $V_r$, and then apply a random “selector projection” $P_\Omega$ to the image $AV_r$. Our primary goal is to obtain a lower bound on

$$\inf_{v \in V_r} \|P_\Omega Av\|_2^2 = \inf_{v \in V_r} \sum_{i=1}^n \delta_i \langle Av, e_i \rangle^2. \quad (2.6)$$

Thanks to the nature of circulant matrices, there is a standard representation of $\{Av : v \in V_r\}$ via the Fourier transform. Let $F$ be the (un-normalized) Fourier transform, i.e., $F_{j,k} = e^{-2\pi i jk/n}$, (which we treat as a “real operator” from $\mathbb{R}^n$ onto the image of $\mathbb{R}^n$ in order to avoid working with $\mathbb{C}^n$) and set $\hat{v} = Fv$. If $D_x = \text{diag}((\langle W_i, x \rangle)_{i=1}^n)$ then

$$Av = F^{-1} D_\hat{v} F \xi.$$

We will consider a more general set of matrices:

**Definition 2.6** An orthogonal matrix $O$ is of Hadamard type with constant $\beta$ if for every $i,j \in [n]$, $|O_{i,j}| \leq \beta/\sqrt{n}$.

In what follows we will fix three matrices, $U, W$ and $O$, all of which are of Hadamard type with constant $\beta$, and for $x \in \mathbb{R}^n$ we set

$$\Gamma_x = \sqrt{n} UD_{Wx} O,$$

where $D_{Wx} = \text{diag}((\langle W_i, x \rangle)_{i=1}^n)$. Clearly, the representation of $Av$ is precisely of this form: if $A$ is the complete circulant matrix with the generator $\xi$ then for every $v \in \mathbb{R}^n$, $Av = \sqrt{n} UD_{Wv} O \xi$ for the choice of $U = n^{-1/2} F^{-1}$ and $W = O = n^{-1/2} F$; in this case $\beta = 1$.

From here on, for $V \subset \mathbb{R}^n$ set

$$\Gamma_V = \{\sqrt{n} UD_{Wv} O : v \in V\};$$

naturally, the set of matrices we will be interested in is $\Gamma_{V_r}$.

Observe that if $\xi$ is an isotropic random vector then for every $v \in S^{n-1}$, $E\|\Gamma_v \xi\|_2^2 = n$, and at least on average, for a single vector $v \in V_r$, one expects to have $\|\Gamma_v \xi\|_2 \sim \sqrt{n}$.

Unfortunately, showing that $\inf_{v \in V_r} \|\Gamma_v \xi\|_2 \geq c\sqrt{n}$ does not lead to a nontrivial lower bound on (2.6). To see why, set

$$x^1 = (\sqrt{n}, 0, \ldots, 0) \quad \text{and} \quad x^2 = (1, \ldots, 1).$$

Both $x^1$ and $x^2$ have a Euclidean norm of $\sqrt{n}$, but any attempt of selecting a random subset of coordinates of cardinality $m \ll n$ fails miserably for $x^1$ and succeeds for $x^2$: typically, $P_\Omega x^1 = 0$ while $\|P_\Omega x^2\|_2 = \sqrt{m}$. We will be looking at this type of “good behavior”, exhibiting a (one sided) standard shrinking phenomenon. The term “one-sided standard shrinking” used in this context usually refers to a random projection operator $T$ of rank $m$, for which, with high probability,

$$\|Tv\|_2 \geq c\sqrt{m/n} \|v\|_2 \quad \text{for all vectors of interest.}$$
The operator we are interested in is indeed random, and of the form \( T = P_\Omega \) – a random coordinate projection – but as the example of \( x^i \) shows, \( P_\Omega \) may map \( x \) to 0 even if \( x \) has a large norm – unless one imposes some additional condition on \( x \).

The condition we will focus on here is that \( x \) has a regular coordinate structure, that is, for suitable constants \( \alpha \) and \( \theta \),

\[
\left\{ i : |x_i| \geq \|x\|_2 \frac{\alpha}{\sqrt{n}} \right\} \geq \theta n. \tag{2.8}
\]

The notion of regularity in (2.8) implies that \( |x_i| \) is at least \( \|x\|_2 / \sqrt{n} \) for a large subset of coordinates – of cardinality that is proportional to the dimension \( n \). That set of coordinates contributes at least a proportion of the Euclidean norm of \( x \), and moreover, for a random choice of \( \Omega \subset [n] \), \( \|P_\Omega x\|_2 \geq c\|x\|_2 \cdot \sqrt{|\Omega|/n} \) with high probability.

Thus, in addition to showing that \( \inf_{v \in \mathcal{V}_r} \|\Gamma_v \xi\|_2 \geq c\sqrt{n} \), we will prove that each of the vectors \( \Gamma_v \xi \) is regular in the sense of (2.8). We will do so by representing a typical realization of the set \( \{\Gamma_v \xi : v \in \mathcal{V}_r\} \) as a subset of the Minkowski sum of two (random) sets \( T_1 + T_2 \) defined in the following way: Let \( H \subset \mathcal{V}_r \) be a fine enough net with respect to the Euclidean distance and set \( T_1 = \{ \Gamma_x \xi : x \in H \} \). For each \( v \in \mathcal{V}_r \), choose \( x = \pi(v) \in H \) minimizing \( \|x-v\|_2 \). Then \( T_2 = \{ \Gamma_{v-\pi(v)} \xi : v \in \mathcal{V}_r \} \). We will show the following properties of the sets \( T_1, T_2 \):

- Every \( t \in T_1 \) satisfies \( \|t\|_2 \gtrsim \sqrt{n} \) and has regular coordinate structure in the sense of (2.8). As a consequence, a random coordinate projection \( P_\Omega \) will not shrink the \( \ell_2 \)-norm of elements in \( T_1 \) by more than a factor of \( \sim \sqrt{\delta} \), and therefore, with high probability,

\[
\inf_{x \in H} \|P_\Omega \Gamma_x \xi\|_2 \geq c\sqrt{\delta n}.
\]

- The set of “random oscillations” \( T_2 \) has Euclidean diameter smaller than \( (c/2)\sqrt{n} \). Thus, its effect is negligible.

What may still appear mysterious is the claim that there is a phase transition in the choice of \( \delta \) – and thus in the required number of measurements. The origin of the phase transition lies in a gap between the cardinality of the net \( H \) and the probability estimate one is likely to have for each \( \Gamma_v \). Indeed, for reasons that will be clarified later, the probability that \( \Gamma_v \xi \) is “well behaved” can be estimated by \( \exp(-cn/r) \). In contrast, as a nontrivial Euclidean net in \( \mathcal{V}_r \), \( |H| \gtrsim \exp(c_1 r \log(\|\Gamma_v \|_2)) \). In the low-sparsity case, when \( n/r \gtrsim r \log(\|\Gamma_v \|_2) \), the individual probability estimate is strong enough to allow uniform control on all the vectors in the net \( H \). In the high-sparsity case that is no longer true, and an additional argument is required to bridge the gap between \( n/r \) and \( r \log(\|\Gamma_v \|_2) \). Specifically, we will show how one may “transfer information” from a set of cardinality \( \exp(cn/r) \) to the net \( H \) whose cardinality is much larger – of the order of \( \exp(cr \log(\|\Gamma_v \|_2)) \).

2.5 Notation

Throughout this article, absolute constants are denoted by \( c, c_1, C, \) etc. The notation \( c(L) \) refers to a constant that depends only on the parameter \( L \); \( a \sim b \) implies that there are absolute constants \( c \) and \( C \) for which \( ca \leq b \leq Ca \); and \( a \sim_L b \) means that the constants \( c \) and \( C \) depend only on \( L \). The analogous one-sided notation is \( a \lesssim b \) and \( a \lesssim_L b \). Constants whose values remain unchanged throughout the article are denoted by \( \kappa_1, \kappa_2, \) etc.
For $1 \leq p \leq \infty$ let $\ell^p_n$ be the normed space $(\mathbb{R}^n, \| \cdot \|_p)$ and set $B^n_p$ to be its unit ball. $S^{n-1}$ is the Euclidean unit sphere in $\mathbb{R}^n$. The expectation is denoted by $\mathbb{E}$ and $\text{Pr}$ denotes the probability of an event. The $L_p$-norm of a random variable $X$ is denoted $\|X\|_{L_p} = (\mathbb{E}|X|^p)^{1/p}$.

We also recall that $[n] = \{1, \ldots, n\}$.

3 Small ball estimates and chaining

3.1 The random generator

Recall that the random vector $\xi$ we are interested in has independent coordinates $(\xi_i)_{i=1}^n$ that are mean-zero, variance 1 and $L$-subgaussian. In particular, $\xi$ is an isotropic, $L$-subgaussian random vector.

A simple observation is that the $\xi_i$'s satisfy a small-ball property: there are positive constants $c_1$ and $c_2$ that depend only on $L$ for which

$$
\sup_{u \in \mathbb{R}} \text{Pr}(|\xi_i - u| \geq c_1) \geq c_2.
$$

(3.1)

Indeed, for any $u \in \mathbb{R}$, $\|\xi_i - u\|_{L_2} \sim \max\{\|\xi_i\|_{L_2}, |u|\}$, and thus $\|\xi_i - u\|_{L_4} \leq c_3 L \|\xi_i - u\|_{L_2}$ for a suitable absolute constant $c_3$. The small-ball property (3.1) is an immediate outcome of the Paley-Zygmund inequality (see, e.g., [17, Lemma 7.16]) applied to each $X_u = |\xi_i - u|$.

The small-ball property (3.1) tensorizes, leading to a vector small-ball property for $\xi = (\xi_i)_{i=1}^n$. To formulate this property, let $\|\Gamma\|_{HS}$ and $\|\Gamma\|_{2 \to 2}$ denote the Hilbert-Schmidt (Frobenius) and operator norms of a matrix $\Gamma$, respectively, and set

$$
d_\Gamma = \left( \frac{\|\Gamma\|_{HS}}{\|\Gamma\|_{2 \to 2}} \right)^2.
$$

Theorem 3.1 [40] There exists an absolute constant $c$ for which the following holds. Let $X_1, \ldots, X_n$ be independent random variables that satisfy for some $t > 0$ and $0 < p < 1$

$$
\sup_{u \in \mathbb{R}} \text{Pr}(|X_i - u| \leq t) \leq p.
$$

Then, for $X = (X_1, \ldots, X_n)$ and every matrix $\Gamma : \mathbb{R}^n \to \mathbb{R}^m$,

$$
\text{Pr}(\|\Gamma X\|_2 \leq t \|\Gamma\|_{HS}) \leq \left( \frac{1}{2} \right)^{cd_\Gamma}.
$$

The small-ball property for individual $\xi_i$'s from (3.1) and Theorem 3.1 imply that the random vector $\xi$ satisfies a small-ball estimate.

Corollary 3.2 There exist constants $\kappa_1$ and $\kappa_2$ that depend only on $L$ such that, for any matrix $\Gamma : \mathbb{R}^n \to \mathbb{R}^m$,

$$
\text{Pr}(\|\Gamma \xi\|_2 \leq \kappa_1 \|\Gamma\|_{HS}) \leq \left( \frac{1}{2} \right)^{\kappa_2 d_\Gamma}.
$$

(3.2)
It should be noted that a subgaussian vector with independent coordinates is not the only random vector that satisfies a small-ball estimate like (3.2). Moreover, such small-ball estimates can be used to extend our main result to a larger class of generators – a direction we will not explore further in this work.

The other type of bound we require deals with the way the moments of \( \|\xi\| \) grow, for an arbitrary norm \( \|\| \) on \( \mathbb{R}^n \). Unlike Corollary 3.2, this feature does not require \( \xi \) to have independent coordinates, and it holds for any (isotropic) subgaussian random vector (see, for example, [24, Theorem 2.3]).

**Theorem 3.3** There exists an absolute constant \( c \) for which the following holds. Let \( \xi \) be an isotropic, \( L \)-subgaussian random vector in \( \mathbb{R}^n \) and set \( G = (g_1, \ldots, g_n) \) to be the standard gaussian vector in \( \mathbb{R}^n \). Let \( \|\| \) be a norm on \( \mathbb{R}^n \) and set \( B^o \) to be the unit ball of its dual norm. Then for every \( p \ge 1 \),

\[
(\mathbb{E}\|\xi\|^p)^{1/p} \le cL(\mathbb{E}\|G\| + \sqrt{p} \sup_{t \in B^o} \|t\|_2).
\]

We will consider two families of norms associated with the non-increasing rearrangement of the coordinates of a vector.

**Definition 3.4** Let \((x^*_i)_{i=1}^n\) denote the non-increasing rearrangement of \((|x_i|)_{i=1}^n\). For \( k \in [n] \), set

\[
\|x\|_{[k]} = \max_{|I|=k} \left( \sum_{i \in I} x_i^2 \right)^{1/2} = \left( \sum_{i=1}^k (x_i^*)^2 \right)^{1/2}.
\]

When \( k = n \), the norm \( \|\|_{[k]} \) is simply the Euclidean norm, and the unit ball of the dual norm is just the standard Euclidean unit ball. When \( 1 \le k < n \), the dual unit ball consists of the set of unit-\( \ell_2 \)-norm \( k \)-sparse vectors, that is:

\[
V_k = \{ v \in S^{n-1} : \|v\|_0 \le k \}.
\]

To apply Theorem 3.3 to \( \|\|_{[k]} \) one has to control \( \mathbb{E}\|G\|_{[k]} = \mathbb{E}(\sum_{i=1}^k (g_i^*)^2)^{1/2} \). The following result for subgaussian random variables does not require independence.

**Lemma 3.5** [23] Let \( Z_1, \ldots, Z_n \) be mean-zero and \( L \)-subgaussian random variables such that \( \max_{i \in [n]} \|Z_i\|_{L_2} \le M \). Then

\[
\mathbb{E}(\sum_{i=1}^k (Z_i^*)^2)^{1/2} \le cLM \sqrt{k \log(en/k)}.
\]

**Proof.** Since the proof of this result is not provided in [23], we give it here for convenience. Since the \( Z_i \) are \( L \)-subgaussian, there exist constants \( c_0, c_1 > 0 \) such that (see e.g. [17, Proposition 7.23])

\[
\mathbb{E}\exp\left( c_0 \frac{Z_i^2}{L^2\|Z_i\|_{L_2}^2} \right) \le c_1.
\]
By Jensen’s inequality and concavity of the logarithm

\[
\left[ \mathbb{E}\left( \frac{1}{k} \sum_{i=1}^{k} (Z_i^*)^2 \right)^{1/2} \right] ^2 \leq \mathbb{E}\left( \frac{1}{k} \sum_{i=1}^{k} (Z_i^*)^2 \right) \leq c_0^{-1} M^2 L^2 \mathbb{E}\left( \frac{1}{k} \sum_{i=1}^{k} \log(\exp(c_0 (Z_i^*)^2 / (L\|Z_i^*\|_2)^2)) \right)
\]

\[
\leq c_0^{-1} M^2 L^2 \log \left( \frac{1}{k} \sum_{i=1}^{k} \mathbb{E} \exp \left( c_0 \frac{(Z_i^*)^2}{L^2\|Z_i^*\|_2^2} \right) \right) \leq c_0^{-1} M^2 L^2 \log \left( \frac{1}{k} \sum_{i=1}^{n} \mathbb{E} \exp \left( c_0 \frac{Z_i^2}{L^2\|Z_i\|_2^2} \right) \right)
\]

\[
\leq c_0^{-1} M^2 L^2 \log(c_1 n/k).
\]

Rearranging this inequality and adjusting constants yields the claim.

For the choice \( Z_i = \xi_i \), it follows from Lemma 3.5 and Theorem 3.3 that for every \( p \geq 1 \) and \( k \in [n] \),

\[
(\mathbb{E}\|\xi\|_{[k]}^p)^{1/p} \leq cL \left( \sqrt{k \log(en/k)} + \sqrt{p} \right). \tag{3.3}
\]

The second family of norms we require is a generalization of the first one. Let \( \Gamma \) be a matrix and set

\[
\|x\| = \|\Gamma x\|_{[k]} = \left( \sum_{i=1}^{k} (\langle \Gamma x, e_i \rangle^*)^2 \right)^{1/2} = \sup_{t \in \Gamma^* V_k} \langle x, t \rangle,
\]

where the last equality follows from \( \|z\|_{[k]} = \sup_{t \in V_k} \langle z, t \rangle \).

**Lemma 3.6** Let \( \xi \) be an isotropic, \( L \)-sugaussian random vector. Then for every matrix \( \Gamma \) and any \( p \geq 1 \),

\[
(\mathbb{E}\|\Gamma \xi\|_{[k]}^p)^{1/p} \leq cL \left( \sqrt{k \log(en/k)} \max_{1 \leq i \leq n} \|\Gamma^* e_i\|_2 + \sqrt{p} \sup_{t \in V_k} \|\Gamma^* t\|_2 \right)
\]

**Proof.** By Theorem 3.3, it suffices to estimate \( \mathbb{E}\sup_{t \in \Gamma^* V_k} \langle x, t \rangle = \mathbb{E}\left( \sum_{i=1}^{k} (\langle G, \Gamma^* e_i \rangle^*)^2 \right)^{1/2} \) for the standard gaussian vector \( G \). This expectation may be controlled using Lemma 3.5 for the choice of \( Z_i = \langle G, \Gamma^* e_i \rangle \) and that fact that \( M = \max_{i \in [n]} \|Z_i\|_{L_2} = \max_{i \in [n]} \|\Gamma^* e_i\|_2 \). ■

The following standard relation between moments and tails is recorded for convenience as it will be used frequently in the sequel. Its proof is follows immediately from Markov’s inequality.

**Lemma 3.7** Assume that a random variable \( Z \) satisfies \( (\mathbb{E}|Z|^p)^{1/p} \leq A \) for some \( p > 0 \) and \( A > 0 \). Then

\[
Pr(|Z| \geq eA) \leq e^{-p} \quad \text{and} \quad Pr(|Z| \geq 2A) \leq 2^{-p}.
\]

As noted above, the matrices we will be interested in are of the form

\[
\Gamma_v = \sqrt{n} U D W_v O,
\]

where \( U, W \) and \( O \) are Hadamard type matrices with constant \( \beta \) and \( v \in \mathbb{R}^n \). Thus,

\[
\|\Gamma_v\|_{HS} = \sqrt{n}\|v\|_2, \quad \|\Gamma_v\|_{2-2} \leq \sqrt{n}\|W_v\|_\infty \leq \beta\|v\|_0^{1/2},
\]

13
and for every $i \in [n]$,

$$
\| \Gamma^*_i e_i \|_2 = \sqrt{n} \left( \sum_{\ell=1}^n \langle W_\ell, v \rangle^2 \cdot U_{i,\ell}^2 \right)^{1/2} \leq \beta \| v \|_2.
$$

Combining Corollary 3.2, Lemma 3.6 and Lemma 3.7, one has the following:

**Corollary 3.8** There exist constants $\kappa_1$, $\kappa_2$ and $\kappa_3$ that depend only on $L$ and $\beta$ for which the following holds. If $v \in V_r$ then

$$
Pr(\| \Gamma v \xi \|_2 \leq \kappa_1 \sqrt{n} \| v \|_2) \leq \left( \frac{1}{2} \right)^{\kappa_2 n / \beta^2 r},
$$

(3.4)

and if $v \in \mathbb{R}^n$ and then with probability at least $1 - \exp(-p)$,

$$
\| \Gamma v \xi \|_[k] \leq \kappa_3 (\| v \|_2 \sqrt{k \log(en/k)} + \sqrt{\beta} \cdot \sqrt{n} \| Wv \|_\infty).
$$

(3.5)

**Remark 3.9** In what follows, (3.4) and (3.5) are the key features of $\xi$ that we will use. To establish those two facts we used rather special properties of $\xi$, but while those special properties (for example, that $\xi$ is stochastically dominated by a gaussian vector) are highly restrictive, (3.4) and (3.5), or even further relaxations of the two, actually hold for a wider variety of random vectors. We will pursue this direction in a future contribution.

### 3.2 Definitions and basic facts

Let $(T, d)$ be a metric space. A subset $T' \subset T$ is called $\varepsilon$-separated if for every $x, y \in T'$, $d(x, y) \geq \varepsilon$. By a standard comparison of packing and covering numbers, see e.g. [17, Lemma C.2], if $T'$ is a maximal $\varepsilon$-separated subset of $T$, it is also an $\varepsilon$-cover: that is, for every $x \in T$ there is some $y \in T'$ for which $d(x, y) \leq \varepsilon$.

In what follows we denote by $N(T, d, \varepsilon)$ the cardinality of a minimal $\varepsilon$-cover of $T$. Note that if $T \subset \mathbb{R}^n$ and $d$ is a norm on $\mathbb{R}^n$ whose unit ball is $B$, then $N(T, d, \varepsilon)$ is the minimal number of translates of $\varepsilon B$ needed to cover $T$. Therefore, we will sometimes abuse notation and write $N(T, \varepsilon B)$ instead of $N(T, d, \varepsilon)$.

We will also use the language of Generic Chaining [41] extensively.

**Definition 3.10** Given a metric space $(T, d)$, an admissible sequence $(T_s)_{s \geq 0}$ is a sequence of subsets of $T$, with $|T_0| = 1$ and $|T_s| \leq 2^{2^s}$. Together with an admissible sequence one defines a collection of maps $\pi_s : T \to T_s$. Usually, $\pi_s t$ is chosen as a nearest point to $t$ in $T_s$ with respect to the metric $d$. For $s \geq 0$ set

$$
\Delta_s t = \pi_{s+1} t - \pi_s t.
$$

Let us define several parameters that will be used throughout the proof of Theorem 2.5.

**Definition 3.11** For $r \in [n]$ set

$$
\rho = 10 \log_2 e \cdot \max \left\{ 1, \frac{\log(ek)}{\log(en/r)} \right\}.
$$

(3.6)
Using the notation introduced earlier, put
\[ \kappa_4 = \min \left\{ \kappa_2^2, \frac{\kappa_1^2}{64 \kappa_2^2 L^2 \beta^2} \right\}, \] (3.7)
and observe that \( \kappa_4 \) depends only on \( L \) and \( \beta \). Moreover, without loss of generality, \( \kappa_1 \leq 1 \), and \( \kappa_3, L, \beta \geq 1 \).

Set \( s_0 \) and \( s_1 \) to satisfy
\[ 2^{s_0} = \frac{\kappa_4 n}{r} \quad \text{and} \quad 2^{s_1} = pr \log(en/r) \]
and without loss of generality we will assume that \( s_0 \) and \( s_1 \) are integers. Finally, let
\[ \alpha_r = \max \left\{ 1, \log \left( \frac{pr \log(en/r)}{\kappa_4 (n/r)} \right) \right\} = \max \{1, \log(2^{s_1 - s_0})\}. \]

A key part in the proof of Theorem 2.5 requires a different argument when \( 2^{s_0} \geq 2^{s_1} \) and when the reverse inequality holds. As we indicated earlier, we will call the former the “low-sparsity” case, and the latter the “high-sparsity” case. It is straightforward to verify that in the low-sparsity case \( (2^{s_0} \geq 2^{s_1}) \), this corresponds to
\[ r \leq c \kappa_4^{1/2} \sqrt{\frac{n}{\log(cn/\kappa_4)}}, \quad \rho = 10 \log_2 e, \quad \text{and} \quad \alpha_r = 1, \]
while in the “high-sparsity” case,
\[ r \geq c \kappa_4^{1/2} \sqrt{\frac{n}{\log(cn/\kappa_4)}}, \]
if \( r \leq \sqrt{n} \) then \( \rho = 10 \log_2 e \), and otherwise, \( \rho = 10 \log_2 e \cdot \frac{\log(er)}{\log(en/r)} \). Thus,
\[ \alpha_r = \log \left( \frac{cr^2}{\kappa_4 n} \cdot \log \left( \frac{en}{r} \right) \right) \quad \text{if} \quad r \leq \sqrt{n}, \]
and
\[ \alpha_r = \log \left( \frac{cr^2}{\kappa_4 n} \cdot \log(er) \right) \quad \text{otherwise}. \]

Let us mention that \( \kappa_1, \kappa_2, \kappa_3 \) and \( \kappa_4 \) are all constants that depend only on \( L \) and \( \beta \) – an observation that will be used throughout this article.

### 3.3 Covering of \( V_r \)

Let us begin by constructing (a part of) an admissible sequence for \( V_r \).

**Lemma 3.12** Let \( 1 \leq r \leq n/2 \) and \( s_1 \) as above. There exists an admissible sequence \((V_{r,s})_{s \geq s_1}\) for which
\[ \sup_{v \in V_r} \sum_{s \geq s_1} (\sqrt{n} + \sqrt{r} 2^{s/2}) \| \Delta_s v \|_2 \leq \frac{c}{n^{3/2}}, \]
where \( \pi_s v \) is the nearest point to \( v \) in \( V_{r,s} \) with respect to the Euclidean norm, \( \Delta_s v = \pi_{s+1} v - \pi_s v \) and \( c \) is an absolute constant.
We note that the exponent $3/2$ above is rather arbitrary. We could easily replace it by a larger one by adjusting constants.

**Proof.** Let $V_{r,s}$ be a maximal $\varepsilon_s$ separated subset of $V_r$ with respect to the Euclidean norm and of cardinality $2^{2s}$. Thus it is also an $\varepsilon_s$-cover of $V_r$ and

$$\|\Delta_s v\|_2 \leq \|\pi_{s+1} v - v\|_2 + \|\pi_s v - v\|_2 \leq 2\varepsilon_s.$$ 

To estimate $\varepsilon_s$, observe that by a standard volumetric estimate, see e.g. [17, Proposition C.3], and summing over all $\binom{n}{r}$ possible support subsets of $[n]$ of cardinality $r$, for any $0 < \varepsilon < 1/2$, the cardinality of a maximal $\varepsilon$-separated subset of $V_r$ is at most

$$\binom{n}{r} \left( 1 + \frac{2}{\varepsilon} \right)^n \leq \left( \frac{3en}{r\varepsilon} \right)^r.$$ 

Hence,

$$\varepsilon_s \leq 2^{-2s/r} \left( \frac{3en}{r} \right),$$

and

$$\sup_{v \in V_r} \sum_{s \geq s_1} 2^{s/2}\|\Delta_s v\|_2 \leq 2 \sum_{s \geq s_1} 2^{s/2}\varepsilon_s \leq c_0 \left( \frac{n}{r} \right) \cdot \sum_{s \geq s_1} 2^{s/2-2s/r}.$$ 

It is straightforward to verify that for every $s \geq s_1$,

$$2^s/r \geq 2(s/2). \tag{3.8}$$

This follows for $s_1$ because $2^{s_1} = \rho r \log(en/r)$ and

$$\frac{2^{s_1}}{r} = (10 \log_2 e) \cdot \max \left\{ \log \left( \frac{en}{r} \right), \log(er) \right\} \geq s_1,$$

and for $s > s_1$ because $s \mapsto 2^s/s$ is increasing. Therefore,

$$\sup_{v \in V_r} \sum_{s \geq s_1} 2^{s/2}\|\Delta_s v\|_2 \leq c_0 \frac{n}{r} \cdot \sum_{s \geq s_1} 2^{-2s/(2r)},$$

which is dominated by a geometric series with power $2^{-(s_1 + 1)/2r} = 2^{-(\rho/2)\log(en/r)} \leq 1/4$. Therefore,

$$\frac{n}{r} \sum_{s \geq s_1} 2^{-2s/2r} \sim \frac{n}{r} \cdot 2^{-2s_1/(2r)} \leq e^{-1} \left( \frac{r}{en} \right)^{\rho/2\log_2 e - 1}.$$ 

Note that

$$\left( \frac{r}{en} \right)^{\rho/2\log_2 e - 1} \leq \frac{1}{(en)^2}. \tag{3.9}$$

Indeed, if $r \leq n/r$, i.e., if $r \leq \sqrt{n}$, then $\rho/\log_2 e \geq 10$ and

$$\left( \frac{r}{en} \right)^{(\rho/2\log_2 e)-1} \leq \left( \frac{1}{\sqrt{en}} \right)^4 \leq \frac{1}{(en)^2};$$

16
otherwise, \( \sqrt{n} \leq r \leq n/2 \) and \( \rho/\log_2 e = 10 \log(er)/\log(en/r) \) so that
\[
\log \left( \left( \frac{en}{r} \right)^{(\rho/2\log_2 e) - 1} \right) = \log \left( \frac{en}{r} \right) \left[ \frac{5 \log(er)}{\log(en/r)} - 1 \right] \geq \log \left( (en)^4 \right),
\]
so that (3.9) holds also in this case. Therefore,
\[
\sup_{v \in V_r} \sum_{s \geq s_1} (\sqrt{n} + \sqrt{r}2^{s/2}) \|\Delta_s v\|_2 \leq \frac{c_1}{n^{3/2}}
\]
for an absolute constant \( c_1 \).

4 The structure of a typical \( \{\Gamma_v \xi : v \in V_r\} \)

The main component in the proof of Theorem 2.5 is a structural result on a typical realization of the random set \( \{\Gamma_v \xi : v \in V_r\} \).

**Theorem 4.1** There exist constants \( c_0, \ldots, c_3 \) that depend only on \( L \) and \( \beta \) for which the following holds. With probability at least \( 1 - 2^{-c_0 \min\{2^s, 2^4\}} \),
\[
\{\Gamma_v \xi : v \in V_r\} \subset T_1 + T_2,
\]
where
\[
|T_1| \leq 2^{2^{s_1}} \quad \text{and} \quad T_2 \subset c_1 n^{-3/2} B_2^n.
\]
Moreover, for every \( t \in T_1 \), there is a (random) set \( I = I(t) \subset [n] \) of cardinality at least
\[
|I| \geq c_2 \frac{n}{\alpha_r^2 \log \alpha_r},
\]
for which
\[
\sum_{i \in I} \langle \Gamma_I \xi, e_i \rangle^2 \geq (\kappa_1/4)^2 n \quad \text{and} \quad \max_{i \in I} |\langle \Gamma_I \xi, e_i \rangle| \leq c_3 \alpha_r \sqrt{\log(e \alpha_r)}.
\]

Theorem 4.1 implies that a typical realization of \( \{\Gamma_v \xi : v \in V_r\} \) is just a perturbation of the (random) set \( T_1 \), and that \( T_1 \) consists of vectors with a regular coordinate structure.

Let us examine Theorem 4.1 in the two cases: when \( s_0 \geq s_1 \) and when \( s_0 < s_1 \). In the former (the low-sparcity case), \( \alpha_r = 1 \), and the claim is that with probability at least \( 1 - 2^{-c_0 \rho \log(en/r)} \), for every \( t \in T_1 \), there is \( I \subset [n] \) of cardinality \( |I| \geq c_2 n \) for which
\[
\|P_I t\|_2 \geq (\kappa_1/4)\sqrt{n} \quad \text{and} \quad \|P_I t\|_\infty \leq c_3.
\]
This forces \( I \) to contain at least \( \sim c_2 n \) coordinates that are larger than a constant, and thus, each one of the vectors \( t \in T_1 \) has a regular coordinate structure in the sense of (2.8).

When \( s_1 > s_0 \), a similar type of claim holds, but with probability at least \( 1 - 2^{-c_0 \kappa_4 n/r} \), and the regularity condition on the coordinates of \( t \in T_1 \) is slightly weaker: one no longer has a subset of cardinality that is proportional to \( n \) consisting of coordinates that are larger than a constant, but rather a (marginally) smaller set \( I \); each \( P_I t \) has a large \( \ell_2 \) norm and a small \( \ell_\infty \) norm.

Thanks to this information on the structure of a typical \( \{\Gamma_v \xi : v \in V_r\} \), one may establish the required lower bound on \( \inf_{v \in V_r} \|P_I \Gamma_v \xi\|_2 \).
Corollary 4.2 There exist constants $c_0$, $c_1$ and $c_2$ that depend only on $L$ and $\beta$ for which the following holds. Let

$$\delta n \geq c_0 (r^2 \log \alpha_r) \cdot pr \log (en/r),$$

with $\rho$ defined in (3.6) and set $(\delta_i)_{i=1}^n$ to be independent selectors with mean $\delta$. Then with probability at least $1 - 2^{-c_1 \min\{2^{s_0}, 2^{s_1}\}}$,

$$\inf_{v \in V_v} \sum_{i=1}^n \delta_i \langle \Gamma_v \xi, e_i \rangle^2 \geq c_2 \delta n.$$

Proof. Let $\xi$ be a realization of the event from Theorem 4.1 – which holds with probability at least $1 - 2^{-c_0 \min\{2^{s_0}, 2^{s_1}\}}$ relative to $\xi$, and let $(\delta_i)_{i=1}^n$ be independent selectors with mean $\delta$ that are also independent of $\xi$.

Using the notation of Theorem 4.1, let $\Gamma_v \xi = t + y$ for $t \in T_1$ and $y \in T_2$; hence

$$\left( \sum_{i=1}^n \delta_i \langle \Gamma_v \xi, e_i \rangle^2 \right)^{1/2} \geq \inf_{t \in T_1} \left( \sum_{i=1}^n \delta_i t_i^2 \right)^{1/2} - \sup_{y \in T_2} \left( \sum_{i=1}^n \delta_i y_i^2 \right)^{1/2} \geq \inf_{t \in T_1} \left( \sum_{i=1}^n \delta_i t_i^2 \right)^{1/2} - \frac{c_1}{n^{3/2}}$$

for an absolute constant $c_1$. It suffices to show that

$$\inf_{t \in T_1} \sum_{i=1}^n \delta_i t_i^2 \geq c_2 \delta n,$$

the right hand being larger than $2c_1/n^3$, where $c_2$ is a suitable constant. Fix $t \in T_1$, let $I = I(t)$ be the set identified by Theorem 4.1 and put $x = P_I t$. Thus,

$$\|x\|_2 \geq (\kappa_1/4) \sqrt{n}, \text{ and } \|x\|_\infty \leq c_3 (L, \beta) \alpha_r \sqrt{\log(e \alpha_r)}.$$

(4.1)

By a straightforward application of Bernstein’s inequality,

$$Pr \left( \left| \sum_{i \in I} (\delta_i - \delta) x_i^2 \right| \geq w \right) \leq 2 \exp \left( -c_4 \min \left\{ \frac{w^2}{\delta \sum_{i \in I} x_i^2}, \frac{w}{\max_{i \in I} x_i^2} \right\} \right).$$

Observe that $\sum_{i \in I} x_i^4 \leq \|x\|^2_\infty \sum_{i \in I} x_i^2$, and thus, for $w = (\delta/2) \sum_{i \in I} x_i^2$, the probability estimate becomes

$$2 \exp \left( -c_4 \delta \|x\|^2_2 / \|x\|^2_\infty \right) \leq 2 \exp \left( -c_5 (L, \beta) \frac{\delta n}{\alpha_r^2 \log(e \alpha_r)} \right).$$

By a union bound, with probability at least

$$1 - 2 |T_1| 2 \exp \left( -c_0 \frac{\delta n}{\alpha_r^2 \log(e \alpha_r)} \right),$$

relative to $(\delta_i)_{i=1}^n$, this implies that, for every $t \in T_1$,

$$\sum_{i \in I(t)} \delta_i t_i^2 \geq \sum_{i \in I(t)} \delta_i t_i^2 \geq \frac{\delta}{2} \sum_{i \in I(t)} x_i^2 \geq \frac{\kappa_1^2}{32} \delta n.$$

The claim follows by setting

$$\delta n \geq c_5^{-1} (r^2 \log \alpha_r) \cdot 2^{s_1+1} = c_7 (L, \beta) \cdot \alpha_r^2 \log(e \alpha_r) \cdot pr \log(en/r).$$
The proof of Theorem 4.1 is based on the following idea: \((V_{r,s})_{s \geq s_1}\) will be selected as an maximal \(\varepsilon_s\)-separated subset of \(V_r\) and \(T_1 = \{\Gamma_s \xi : v \in V_{r,s}\}\). We will show that for every \(v \in V_r\), \(v - \pi_{s_1} v = \sum_{s \geq s_1} \Delta_s v\) is small enough to ensure that with high probability,

\[
\sup_{v \in V_r} \|\Gamma_{v - \pi_{s_1} v} \xi\|_2 \leq \sum_{s \geq s_1} \|\Delta_s v\|_2 \leq \frac{c'}{n^{3/2}}
\]

for \(c'\) that depends on \(L\) and \(\beta\). Then, we will turn to the more difficult part of the argument – that with high probability, for every \(v \in V_{r,s_1}\),

\[
\|\Gamma_v \xi\|_2 \geq c\sqrt{n} \quad \text{and} \quad \|\Gamma_v \xi\|_{\theta n} \leq (c/2)\sqrt{n}
\]

(4.2)

for well-chosen \(c\) and

\[
\theta = \begin{cases} 
  c_1 & \text{for } r \leq c_2 \sqrt{\frac{\kappa_4 n}{\log(c_2 n / \kappa_4)}} \\
  \frac{c_1}{\alpha^2 \log(\alpha r)} & \text{for } c_2 \sqrt{\frac{\kappa_4 n}{\log(c_2 n / \kappa_4)}} \leq r \leq \frac{c_1 n}{\log^2(n)} 
\end{cases}
\]

(4.3)

where all constants \(c, c_1, c_2, c_3, c_4\) only depend on \(L\) and \(\beta\) and \(\kappa_4\) is defined in (3.7), see (4.8) and the following remarks as well as Lemma 4.10. Moreover, here and in the following, we assume for simplicity that \(\theta n\) is an integer. (The general case may need slightly different constants.) Then, for \(t = \Gamma_v \xi\), one has

\[
\sum_{i = \theta n + 1}^{n} (t_i^*)^2 \geq (c/4)n \quad \text{and} \quad t_{\theta n}^* \leq \left( \frac{\theta n}{\theta n} \sum_{i = 1}^{\theta n} (t_i^*)^2 \right)^{1/2} \leq \frac{c}{2\sqrt{\theta}}.
\]

The set \(I = I(t)\) of indices corresponding to \(t_{\theta n+1}^*, \ldots, t_n^*\) fulfills the properties claimed in Theorem 4.1, i.e., \(T_1\) consists of vectors with a regular coordinate structure.

We begin the proof with its simpler part: a high probability estimate on \(\sup_{v \in V_r} \|\Gamma_{v - \pi_{s_1} v} \xi\|_2\).

**Lemma 4.3** There exist constants \(c\) and \(c_1\) that depend only on \(L\) and \(\beta\) for which the following holds. If \((V_{r,s})_{s \geq s_1}\) is an admissible sequence of \(V_r\), then with probability at least \(1 - 2^{-2^{s_1}}\), for every \(v \in V_r\) and \(s \geq s_1\),

\[
\|\Gamma_{\Delta_s v} \xi\|_2 \leq c \left( \sqrt{n} + 2^{s/2} \sqrt{r} \right) \|\Delta_s v\|_2.
\]

(4.4)

In particular, if \((V_{r,s})_{s \geq s_1}\) is a maximal separated subset of \(V_r\), then with probability at least \(1 - 2^{-2^{s_1}}\),

\[
\sup_{v \in V_r} \|\Gamma_{v - \pi_{s_1} v} \xi\|_2 \leq \frac{c_1}{n^{3/2}}.
\]

**Proof.** The first part of the proof is a straightforward outcome of (3.5). Indeed, if we set \(k = n\) and \(p = 2^{s+3}\), then by Lemma 3.7, with probability at least \(1 - \exp(-2^{-(s+3)})\),

\[
\|\Gamma_{\Delta_s v} \xi\|_2 \leq 4\kappa_3 (\sqrt{n} \|\Delta_s v\|_2 + 2^{s/2} \cdot \sqrt{n} \|W \Delta_s v\|_\infty).
\]
Since \( v \) is \( r \)-sparse, \( \Delta_s v = \pi_{s+1} v - \pi_s v \) is \( 2r \)-sparse, and since \( W \) is a Hadamard type matrix with constant \( \beta \),

\[
\sqrt{n}\|W \Delta_s v\|_\infty = \sqrt{n} \max_{i \in [n]} |\langle W_i, \Delta_s v \rangle| \leq \beta \|\Delta_s v\|_1 \leq \beta \|\Delta_s v\|_0^{1/2} \cdot \|\Delta_s v\|_2.
\]

Therefore,

\[
\|\Gamma \Delta_s v\xi\|_2 \leq 8 \kappa_3 (\sqrt{n} + \sqrt{r} 2^{s/2}) \|\Delta_s v\|_2. \tag{4.5}
\]

There are at most \( 2^{2s} \cdot 2^{2s+1} \leq 2^{2s+2} \) vectors of the form \( \Delta_s v \), and thus, by a union bound, with probability at least \( 1 - 2^{-2^{s+2}} \), (4.5) holds for every \( v \in V_r \) for that choice of \( s \). Summing the probabilities for \( s \geq s_1 \), one has that with probability at least \( 1 - 2^{-2^{s_1+1}} \), for every \( v \in V_r \),

\[
\|\Gamma_{v-\pi_{s_1}} \xi\|_2 = \|\sum s \geq s_1 \|\Gamma \Delta_s v\xi\|_2 \leq \sum s \geq s_1 \|\Gamma \Delta_s v\xi\|_2 \leq 8 \kappa_3 \beta \sum s \geq s_1 \left( \sqrt{n} + \sqrt{r} 2^{s/2} \right) \|\Delta_s v\|_2 \leq \frac{c(L, \beta)}{n^{3/2}},
\]

where the last inequality is just Lemma 3.12.

Lemma 4.3 shows that if we set \( T_2 = \{\Gamma_{v-\pi_{s_1}} \xi : v \in V_r \} \), then with probability at least \( 1 - 2^{-2^s} \), \( \sup_{t \in T_2} \|t\|_2 = \sup_{v \in V_r} \|\Gamma_{v-\pi_{s_1}} \xi\|_2 \leq c(L, \beta)/n^{3/2} \), as required in Theorem 4.1. Therefore, all that is left is to study the structure of \( T_1 = \{\Gamma_{\pi_{s_1}} \xi : v \in V_r \} \), and to show that with high probability, it consists of vectors with a regular coordinate structure. To that end we shall split the argument into two cases: the low-sparsity case, when \( s_0 \geq s_1 \) and the high-sparsity one, in which the reverse inequality holds. The analysis in both cases is based on Corollary 3.8.

**The low-sparsity case**

Assume that \( 2^{s_0} \geq 2^{s_1} \). Then \( \frac{\kappa_4 n}{r} \geq \rho r \log(en/r) \) and in particular, by the choice of \( \kappa_4 \),

\[
\frac{\kappa_2}{2 \beta^2} \cdot \frac{n}{r} \geq \rho r \log \left( \frac{en}{r} \right). \tag{4.6}
\]

Fix \( v \in V_{r,s_1} \). It follows from (3.4) that with probability at least \( 1 - 2^{-\kappa_4 n/r^2} \),

\[
\|\Gamma_v \xi\|_2 \geq \kappa_1 \sqrt{n}. \tag{4.7}
\]

Let \( 0 < \theta < 1 \) to be named later. Observe that by (3.5) for \( k = \theta n \) and \( p = 2 \rho r \log(en/r) = 2^{s_1+1} \), with probability at least \( 1 - 2^{-2^{s_1+1}} \),

\[
\|\Gamma_v \xi\|_k \leq 2 \kappa_3 (\|v\|_2 \sqrt{k \log(en/k)} + \sqrt{\rho r \log(en/r)} \sqrt{n}\|Wv\|_\infty) \leq 2 \kappa_3 (\sqrt{n} \theta \log(e/\theta) + \beta \sqrt{\rho r \log(en/r)} \cdot \sqrt{r}), \tag{4.8}
\]

because \( \|v\|_2 = 1 \) and \( \sqrt{n}\|Wv\|_\infty \leq \beta \sqrt{r} \).

Recall that \( |V_{r,s_1}| \leq 2^{2s_1} \) and thus, by (4.6) and the union bound, with probability at least \( 1 - 2^{-2^{s_1}} \), (4.7) and (4.8) hold for every \( v \in V_{r,s_1} \). All that remains is ensure that

\[
2 \kappa_3 \beta \sqrt{\theta} \log(e/\sqrt{\theta}) \sqrt{n} \leq \frac{\kappa_1}{4} \sqrt{n} \quad \text{and} \quad 2 \kappa_3 \beta \sqrt{\theta} \cdot \sqrt{\rho r \log(en/r)} \leq \frac{\kappa_1}{4} \sqrt{n}.
\]
The first condition holds for the right choice of the constant $\theta = \theta(L, \beta)$. For the second, note that by the definition of $\kappa_4$ in (3.7)

$$p r \log(en/r) = 2^{s_1} \leq 2^{s_0} \leq \frac{\kappa_1^2}{6 \kappa_3^2 L^2 \beta^2} \cdot \frac{n}{r}.$$ 

Therefore,

$$2 \kappa_3 \beta \sqrt{r} \cdot \sqrt{pr \log(en/r)} \leq 2 \kappa_3 \beta \sqrt{r} \cdot \frac{\kappa_1}{8 \kappa_3 L \beta} \cdot \sqrt{\frac{n}{r}} \leq \frac{\kappa_1}{4} \sqrt{n},$$

because $L \geq 1$.

This concludes the proof of Theorem 4.1 in the low sparsity case.

The high-sparsity case

Now consider the case $2^{s_0} \leq 2^{s_1}$, that is $\kappa_4 n/r \leq p r \log(en/r)$, and there is a substantial gap between the individual probability estimate (3.4) and the cardinality of $V_{r,s_1}$, so that a simple union bound does not give a non-trivial probability estimate. The difficulty one faces here is bridging this gap, and the key to the proof in the high-sparsity case is the following result.

**Theorem 4.4** There exist constants $c_1$ and $c_2$ that depend only on $L$ and $\beta$ for which the following holds. If $r \leq c_1 n/\log 4^{-n}$ then with probability at least $1 - 2 \exp(-c_2 n/r)$,

$$\inf_{v \in V_{r,s_1}} \|\Gamma_v \xi\|_2 \geq \frac{\kappa_1}{2}.$$ 

For the proof of Theorem 4.4, one has to ‘transfer’ the lower bound on $\inf_{v \in V_{r,s_0}} \|\Gamma_v \xi\|_2$, which may be obtained directly from (3.4) and the union bound, to the much larger set $V_{r,s_1}$. Thus, it suffices to show that with high probability,

$$\sup_{v \in V_{r,s_1}} \|\|\|\Gamma_v \xi\|_2^2 - \|\Gamma_{\pi v}\|_2^2\|_2 \leq \frac{\kappa_1^2}{4} n,$$ 

for an approximating $\pi v \in V_{r,s_0}$.

To address (4.9), we proceed along the lines of [24] and consider the following, more general situation: let $\mathcal{A}$ be a class of matrices, $|\mathcal{A}| \leq 2^{2^{s_1}}$ and set $(\mathcal{A}_s)_{s \geq s_0}$ to be an admissible sequence of $\mathcal{A}$; that is, $\mathcal{A}_s$ is of cardinality at most $2^{2^s}$. Let $\pi_s A$ to be the nearest point to $A$ in $\mathcal{A}_s$ with respect to the $\|\|_2$ norm, set $\Delta_s A = \pi_{s+1} A - \pi_s A$, and put

$$\gamma_{s_0,s_1}(A) = \sup_{A \in \mathcal{A}} \sum_{s=s_0}^{s_1-1} 2^{s/2} \|\Delta_s A\|_{2 \rightarrow 2}.$$ 

**Lemma 4.5** Let $\xi$ be an isotropic, $L$-subgaussian random vector and set $\xi'$ to be an independent copy of $\xi$. Let $N_\mathcal{A}(\xi) = \sup_{A \in \mathcal{A}} \|A\xi\|_2$ and put $Z = \sup_{A \in \mathcal{A}} |\langle A \xi, A \xi' \rangle - \langle (\pi_{s_0} A) \xi, (\pi_{s_0} A) \xi' \rangle|$. Then, for every $p \geq 1$,

$$\|Z\|_p \leq cL \sup_{A \in \mathcal{A}} \gamma_{s_0,s_1}(A) \|N_\mathcal{A}(\xi)\|_p,$$

for an absolute constant $c$. 

---

21
Since the proof of Lemma 4.5 is contained in the proof of Lemma 3.3 in [24], it will not be presented here.

We will be interested in the specific class of matrices $A = \{ \Gamma_v : v \in V_{r,s_1} \}$:

**Theorem 4.6** There exists constants $c_1$ and $c_2$ that depend only on $L$ and $\beta$ for which the following holds. Let $A = \{ \Gamma_v : v \in V_{r,s_1} \}$ and set $(A_s)_{s \geq s_0}$ to be an admissible sequence of $A$. Then, with probability at least $1 - 2^{-c_1 n^p}$,

$$
\sup_{A \in A} \| \| A \xi \|^2 - \| \pi_{s_0} A \xi \|^2 \| \leq c_2 \gamma_{s_0,s_1}(A) \left( \gamma_{s_0,s_1}(A) + \sqrt{n} \right). 
$$

(4.10)

Before proving Theorem 4.6, let us recall a standard fact that can be established using tail integration.

**Lemma 4.7** Let $Z$ be a nonnegative random variable and assume that

$$
Pr(Z \geq A_1 + uA_2) \leq 2 \exp(-u^2/2) \quad \text{for every } u \geq A_3.
$$

Then, for every $p \geq 1$, $\|Z\|_{L_p} \leq c(A_1 + A_2 \cdot \max\{A_3, \sqrt{p}\})$, and $c$ is an absolute constant.

**Proof of Theorem 4.6.** Denote by $A^j$, $j \in [n]$, the columns of the matrix $A$ and observe that

$$
\| A \xi \|^2 - \| \pi_{s_0} A \xi \|^2 = \langle A \xi, A \xi \rangle^2 - \langle \pi_{s_0} A \xi, \pi_{s_0} A \xi \rangle^2 = \sum_{j,k} \xi_j \xi_k \left( \langle A^j, A^k \rangle - \langle \pi_{s_0} A^j, \pi_{s_0} A^k \rangle \right).
$$

Since each $A$ is of the form $\Gamma_v$ for some $v \in S^{n-1}$, $\langle A^j, A^j \rangle = \| v \|^2 = 1$, and the same holds for $\pi_{s_0} A$. Therefore, $\langle A^j, A^j \rangle - \langle \pi_{s_0} A^j, \pi_{s_0} A^j \rangle = 0$ and all that remains is to control the “off-diagonal” terms,

$$
\sum_{j \neq k} \xi_j \xi_k \left( \langle A^j, A^k \rangle - \langle \pi_{s_0} A^j, \pi_{s_0} A^k \rangle \right) =: F_A.
$$

Applying a standard decoupling argument (see, for example, [24, Theorem 2.4] or [11]) and Lemma 4.5

$$
(\mathbb{E} \sup_{A \in A} |F_A|^p)^{1/p} = \sup_{A \in A} \sup_{A \in A} |\langle A \xi, A \xi \rangle^2 - \langle \pi_{s_0} A \xi, \pi_{s_0} A \xi \rangle^2| \leq c_1 \sup_{A \in A} \sup_{A \in A} \sup_{A \in A} \xi_j \xi_k \left( \langle A^j, A^k \rangle - \langle \pi_{s_0} A^j, \pi_{s_0} A^k \rangle \right) \leq c_2 L \left( \sum_{A \in A} \| \Delta_s A \|_{2 \rightarrow 2} \right). \| N_A(\xi) \|_{L_p} = c_2 L \gamma_{s_0,s_1}(A) \cdot \| N_A(\xi) \|_{L_p}.
$$

Moreover,

$$
\| N_A(\xi) \|^2 \leq \sup_{A \in A} \sup_{A \in A} \| \| A \xi \|^2 - \| \pi_{s_0} A \xi \|^2 \| \leq \sup_{A \in A} \| \| \pi_{s_0} A \xi \|^2 \| \leq \sup_{A \in A} \| \pi_{s_0} A \xi \|^2 \| \leq c_2 L \gamma_{s_0,s_1}(A) \cdot \| N_A(\xi) \|_{L_p} + \sup_{A \in A} \| \pi_{s_0} A \xi \|^2 \|_{L_p}.
$$
By (3.5) for \( k = n \) and \( p = u^2 \geq 2^{s_0 + 3} \), it follows that with probability at least \( 1 - 2 \exp(-u^2/2) \),

\[
\sup_{A \in \mathcal{A}} \| \pi_{s_0} A \xi \|_2 = \sup_{v \in V_{r,s_0}} \| \Gamma_v \xi \|_2 \leq \kappa_3 (\sqrt{n} + u \sqrt{n}) \| W v \|_{\infty} \leq c_3 (L, \beta) (\sqrt{n} + u \sqrt{r}),
\]

where we used that \( \| W v \|_{\infty} \leq \beta \sqrt{r/n} \). Thus, the random variable \( Z = \sup_{A \in \mathcal{A}} \| \pi_{s_0} A \xi \|_2 \) satisfies the conditions of Lemma 4.7 for \( A_1 = c_3 \sqrt{n}, A_2 = c_3 \sqrt{r} \) and \( A_3 = 4 \cdot 2^{s_0/2} \), implying that for every \( p \geq 1 \),

\[
\left\| \sup_{A \in \mathcal{A}} \| \pi_{s_0} A \xi \|_2^2 \right\|_{L_p} \leq (\mathbb{E} Z^{2p})^{1/p} \leq c_4 (L, \beta) (\sqrt{n} + \sqrt{r} \max\{2^{s_0/2}, \sqrt{p}\})^2.
\]

Setting \( p = 2^{s_0} = \kappa_4 n / r \) we obtain

\[
\left\| \sup_{A \in \mathcal{A}} \| \pi_{s_0} A \xi \|_2^2 \right\|_{L_p} \leq c_5 (L, \beta) n;
\]

therefore,

\[
\| (N_A(\xi))^2 \|_{L_p} \leq c_6 (L, \beta) (\gamma_{s_0,s_1}(\mathcal{A}) \| N_A(\xi) \|_{L_p} + n),
\]

implying that

\[
\| N_A(\xi) \|_{L_p} \leq c_7 (L, \beta) \max\{\gamma_{s_0,s_1}(\mathcal{A}), \sqrt{n}\}
\]

and

\[
\left( \mathbb{E} \sup_{A \in \mathcal{A}} \| A \xi \|_2^2 - \| \pi_{s_0} A \xi \|_2^2 \right)^{1/p} \leq c_8 (L, \beta) \gamma_{s_0,s_1}(\mathcal{A}) (\gamma_{s_0,s_1}(\mathcal{A}) + \sqrt{n}).
\]

The claim now follows from Lemma 3.7 and the definition of \( p = \kappa_4 n / r \). \( \square \)

The next step is to estimate \( \gamma_{s_0,s_1}(\mathcal{A}) \) for our choice \( \mathcal{A} = \{ \Gamma_v : v \in V_{r,s_1} \} \). We will construct the admissible sequence \( \mathcal{A}_s = \{ \Gamma_v : v \in V_{r,s} \} \) for \( s_0 \leq s < s_1 \) based on the fact that

\[
\| \Delta_s A \|_{2 \rightarrow 2} = \| \Gamma_{\pi_{s+1}v} - \Gamma_{\pi_{s+1}v} \|_{2 \rightarrow 2} = \sqrt{n} \| W \Delta_s v \|_{\infty},
\]

for \( \Delta_s v = \pi_{s+1}v - \pi_s v \). Hence,

\[
\gamma_{s_0,s_1}(\mathcal{A}) = \sup_{v \in V_{r,s}} \sum_{s=s_0}^{s_1-1} 2^{s/2} \cdot \sqrt{n} \| W \Delta_s v \|_{\infty},
\]

and the admissible sequence will be constructed as maximal separated subsets of \( V_{r,s_1} \) with respect to the norm \( \sqrt{n} \| W (\cdot) \|_{\infty} \).

We will require a well-known fact, due to Carl [8].

**Lemma 4.8** There is an absolute constant \( c \) for which the following holds. Let \( w_1, \ldots, w_n \in \mathbb{R}^n \) that satisfy \( \| w \|_{\infty} \leq K \), put \( \| z \| = \max_{i \in [n]} \langle z, w_i \rangle \) and set \( B \) to be the unit ball with respect to that norm. Then for every \( t > 0 \),

\[
\log N(\sqrt{t} B_1^n, tB) \leq C \frac{K^2 r^2}{t^2} \log^2 (nt^2 / r).
\]

23
In the case we are interested in, \( w_i = \sqrt{n}W_i \) and \( \|w_i\|_\infty \leq \beta \). Moreover, \( V_{r,s_1} \subset V_r \subset \sqrt{r}B_1^n \); therefore,

\[
\log N(V_{r,s_1}, tB) \leq \log N(\sqrt{r}B_1^n, tB) \leq C \frac{\beta^2 r}{t^2} \log^2(nt^2/r).
\] (4.11)

**Corollary 4.9** There is an admissible sequence of \( V_{r,s_1} \), for which, for every \( v \in V_{r,s_1} \),

\[
\sqrt{n}\|W\Delta_s v\|_\infty \leq c\beta 2^{-s/2} \sqrt{\log(en/2^s)}
\]

for an absolute constant \( c \). Therefore,

\[
\sup_{v \in V_{r,s_1}} \sum_{s=s_0}^{s_1-1} 2^{s/2} \cdot \sqrt{n}\|W\Delta_s v\|_\infty \leq c_1 \beta \sqrt{\alpha_r} \log(\alpha_r/\kappa_4).
\] (4.12)

Corollary 4.9 follows from (4.11), a straightforward computation and the definition of \( s_0 \) and \( s_1 \). We omit the details.

**Proof of Theorem 4.4.** Combining the individual small ball estimate in (3.4), Theorem 4.6 and Corollary 4.9, one has that with probability at least \( 1 - 2^{-c_1(L,\beta)n/r} \), for every \( v \in V_{r,s_1} \),

\[
\|\Gamma_{\pi_{s_0} v}\xi\|_2 \geq \kappa_1 \sqrt{n},
\]

and

\[
\|\|\Gamma_v \xi\|_2^2 - \|\Gamma_{\pi_{s_0} v}\xi\|_2^2\| \leq c_2 (L, \beta) \sqrt{n} \cdot \sqrt{\alpha_r} \log(c_2 r).
\]

It is straightforward verify that the latter term is bounded by \( (\kappa_1^2/4)n \) provided that \( r \leq c_3(L, \beta)n/\log^4 n \).

The more difficult step consists in exposing the regular coordinate structure of vectors in a typical \( \{\Gamma_v \xi : v \in V_{r,s_1}\} \), and we will do that by finding a suitable upper bound on

\[
\sup_{v \in V_{r,s_1}} \|\Gamma_v \xi\|_k = \sup_{v \in V_{r,s_1}} \left( \sum_{i \leq k} (\langle \Gamma_v \xi, e_i \rangle^*)^2 \right)^{1/2}.
\] (4.13)

Specifically, the next result identifies the largest possible \( k \) for which (4.13) is smaller than \( (\kappa_1/4)\sqrt{n} \).

**Lemma 4.10** Let \( 2^{s_0} \leq 2^{s_1} \) and \( r \leq c_1 n/\log^4(n) \). Assume that

\[
k \leq c_2 \frac{n}{\alpha_r^2 \log(\alpha_r)}.
\]

Then with probability at least \( 1 - 2^{-c_3^{2s_0}} \)

\[
\sup_{v \in V_{r,s_1}} \|\Gamma_v \xi\|_k \leq \frac{\kappa_1}{4} \sqrt{n}.
\] (4.14)

The constants \( c_1, c_2, c_3 \) only depend on \( L \) and \( \beta \).
Remark 4.11 One should note that an upper bound on the supremum in (4.14) cannot be obtained via an individual estimate and the union bound. The subgaussian property of $\xi$ is enough to ensure that for a fixed $v$, 

$$
(\mathbb{E}\|\Gamma_v\xi\|_p^p)^{1/p} \leq cL \left( \|v\|_2 \sqrt{k \log(en/k)} + \sqrt{p} \|Wv\|_\infty \right).
$$

However, because one only knows that for $v \in V_r$, $\sqrt{n} \|Wv\|_\infty \leq \beta \sqrt{T} \|v\|_2$, individual tail estimates suffice for a uniform bound in $V_{r,s_0}$, but not in the much larger set $V_{r,s_1}$.

Proof. Observe that 

$$
\sup_{v \in V_{r,s_1}} \|\Gamma_v\xi\|_k = \sup_{x \in V_k} \sup_{v \in V_{r,s_1}} \langle \xi, \Gamma_v^* x \rangle.
$$

We will study the supremum of the linear process $w \mapsto \langle \xi, w \rangle$ indexed by the set 

$$
\{\Gamma_v^* x : v \in V_{r,s_1}, x \in V_k\}.
$$

Let $(V_{k,s})_{s \geq s_0}$ be an admissible sequence of $V_k$ which will be specified later on. For $x \in V_k$, we consider $\pi_{s_1} x \in V_{k,s_1}$, whose cardinality is $2^{2^{s_1}}$, and $\pi_{s_0} x \in V_{k,s_0}$, whose cardinality is $2^{2^{s_0}}$ and write, for $v \in V_{r,s_1}$,

$$
\Gamma_v^* x = \frac{\Gamma_v^*(x - \pi_{s_1} x)}{=} H_1 + \frac{\Gamma_v^*(\pi_{s_1} x - \pi_{s_0} \pi_{s_0} x)}{=} H_2 + \frac{\pi_{s_0} \pi_{s_0} x}{=} H_3.
$$

While $H_3$ corresponds to the “starting points” of every chain, the difference between $H_1$ and $H_2$ lies in the “balance” between the contribution of $V_k$ and $V_{r,s_1}$ to each one of them. For $H_1$, there are $\sim 2^{2^{s_1}}$ points $v \in V_{r,s_1}$, but for an admissible sequence for $V_k$ one has

$$
\Gamma_v^*(x - \pi_{s_1} x) = \sum_{s \geq s_1} \Gamma_v^*(\pi_{s+1} x - \pi_s x) = \sum_{s \geq s_1} (\Gamma_v^* \Delta_s x),
$$

and for $s \geq s_1$, $|\{\Delta_s x : x \in V_k\}| \geq 2^{2^{s_1}} = |V_{r,s_1}|$. Hence, it is possible to treat $H_2$ for each $v \in V_{r,s_1}$ separately. In contrast, the situation for $H_2$ is “more balanced”, and requires a different argument.

To deal with $H_1$ in (4.15) let us fix $v \in V_{r,s_1}$ and recall that by Lemma 3.5,

$$
\mathbb{E} \sup_{t \in \Gamma_v^* V_k} \langle G, t \rangle = \mathbb{E}\|\Gamma_v G\|_k = \mathbb{E} \left( \sum_{i=1}^k (\langle G, \Gamma_v^* e_i \rangle)^2 \right)^{1/2} \leq c \sqrt{k \log(en/k)} \max_{1 \leq i \leq n} \|\Gamma_v^* e_i\|_2 \leq c \sqrt{k \log(en/k)}.
$$

By the Majorizing Measures Theorem [41], there exists an admissible sequence of $V_k$ for which

$$
\sup_{x \in V_k} \sum_{s=0}^{\infty} 2^{s/2} \|\Gamma_v^* \Delta_s x\|_2 \sim \mathbb{E} \sup_{t \in \Gamma_v^* V_k} \langle G, t \rangle \leq c \sqrt{k \log(en/k)}.
$$

25

Let us consider a part of that admissible sequence, namely, \((V_{k,s})_{s \geq s_1}\). As \(\xi\) is an isotropic, \(L\)-subgaussian random vector, it follows that for every \(s \geq s_1\) and every \(x \in V_k\), with probability at least \(1 - 2^{-2s+3}\),

\[
|\langle \xi, \Gamma^*_s x \rangle| \leq c L 2^{s/2} \|\Gamma^*_s x\|_2.
\]

Summing for \(s \geq s_1\), one has that with probability at least \(1 - 2^{-2s_1+2}\), for every \(x \in V_k\),

\[
|\langle \xi, \Gamma^*_s (x - \pi_{s_1} x) \rangle| \leq \sum_{s \geq s_1} |\langle \xi, \Gamma^*_s x \rangle| \leq c L \sum_{s \geq s_1} 2^{s/2} \|\Gamma^*_s x\|_2 \leq c L \sqrt{k \log(en/k)}.
\]  

(4.16)

Repeating this argument for every \(v \in V_{r,s_1}\) and applying the union bound, one has that with probability at least \(1 - 2^{-2s_1+1}\), (4.16) holds for every \(v \in V_{r,s_1}\).

Next, let us turn to \(H_2\) in (4.15). We will construct approximating subsets in the following way: let \((V_{r,s})_{s=s_0}^{s_1}\) be the admissible sequence of \(V_{r,s_1}\) used earlier, consisting of maximal separated subsets with respect to the norm \(\sqrt{n} \|W(\cdot)\|_\infty\), and put \(\nu_s\) to be the mesh width of the net \(V_{r,s}\). For every \(s_0 \leq s \leq s_1\) and \(z \in V_{r,s}\), let \(\|\cdot\|_z\) be the ellipsoid norm

\[
\|x\|_z^2 = \|D_{W,z} U^* x\|_2^2 = n \sum_{l=1}^n \langle W_{\ell}, z \rangle^2 \langle U_{\ell}, x \rangle^2,
\]

and set \(T_s(z)\) to be a maximal separated subset in \(V_k\) with respect to \(\|\cdot\|_z\), of cardinality \(2^{2s}\). Denote its mesh width by \(\varepsilon_s(z)\). Thus, for \(s_0 \leq s < s_1\), \(v \in V_{r,s+1}\) and \(x \in V_k\),

\[
\Gamma^*_v x = \Gamma^*_{v_0} x + \Gamma^*_{v_0}(x - x') + \Gamma^*_{v'} x',
\]

(4.17)

where \(v' \in V_{s,v}\) satisfies \(\sqrt{n} \|W(v - v')\|_\infty \leq \nu_s\), and \(x' \in V_k\) belongs to \(T_s(v')\) – the net of \(V_k\) with respect to the norm \(\|\cdot\|_{v'}\), and fulfills

\[
\|\Gamma^*_{v'} (x - x')\|_2 = \|x - x'\|_{v'} \leq \varepsilon_s(v').
\]  

(4.18)

Moreover, the cardinality of \(\bigcup_{v' \in V_{r,s}} T_s(v')\) is at most \(2^{2s} \cdot 2^{2s} \leq 2^{2s+1}\).

The required estimate on \(H_2\) follows once we bound \(\nu_s\) – that is, establish a covering number estimate for \(V_{r,s}\) with respect to the norm \(\sqrt{n} \|W(\cdot)\|_\infty\) – and control \(\varepsilon_s(z)\) with respect to each one of the \(\|\cdot\|_z\) norms. Indeed,

\[
|\langle \xi, \Gamma^*_v x \rangle| \leq |\langle \xi, \Gamma^*_{v_0} x \rangle| + |\langle \xi, \Gamma^*_{v_0}(x - x') \rangle| + |\langle \xi, \Gamma^*_{v'} x' \rangle|
\]

for \(v \in V_{r,s+1}\), \(v' \in V_{r,s}\), \(x \in T_{s+1}(v)\) and \(x' \in T_s(v')\). Since \(\xi\) is isotropic and \(L\)-subgaussian, we have with probability at least \(1 - 2^{-2s+2}\), for every \(v \in V_{r,s+1}\) and \(x \in T_{s+1}(v)\),

\[
|\langle \xi, \Gamma^*_v x \rangle| \leq c L (2^{s/2} \|\Gamma^*_{v_0} x\|_2 + 2^{s/2} \|\Gamma^*_{v_0}(x - x')\|_2) + |\langle \xi, \Gamma^*_{v'} x' \rangle|
\]

\[
\leq c L (2^{s/2} \sqrt{n} \|W(v - v')\|_2 + 2^{s/2} \|x - x'\|_{v'}) + |\langle \xi, \Gamma^*_{v'} x' \rangle|
\]

\[
\leq c L (2^{s/2} \nu_s + 2^{s/2} \sup_{z \in V_{r}} \varepsilon_s(z)) + |\langle \xi, \Gamma^*_{v'} x' \rangle|,
\]

for \(v' \in V_{r,s}\) and \(x' \in \bigcup_{v' \in V_{r,s}} T_s(v')\), hence,

\[
|\langle \xi, \Gamma^*_v x - \Gamma^*_{v'} x' \rangle| \leq c L (2^{s/2} \nu_s + 2^{s/2} \sup_{z \in V_{r}} \varepsilon_s(z)).
\]  

(4.19)
Iterating (4.19), summing for \( s_0 \leq s < s_1 \) and recalling that \( 2^{s_0} = \kappa_4 n/r \), it follows that with probability at least \( 1 - 2^{-c_1(L, \beta) n/r} \), for every \( v \in V_{r,s_1} \) and every \( x \in V_k \),

\[
|\langle \xi, \Gamma_v \pi_{s_1} x - \Gamma_{s_0} \pi_{s_0} x \rangle| \leq c_2(L, \beta) \left( \sum_{s=s_0}^{s_1-1} 2^{s/2} \nu_s + \sum_{s=s_0}^{s_1-1} 2^{s/2} \sup_{z \in V_r} \varepsilon_s(z) \right),
\]

(4.20)

and \( \pi_{s_0} v \in V_{r,s_0} \), \( \pi_{s_0} x \in \bigcup_{v \in V_{r,s_0}} T_s(v) \).

The first sum in (4.20) has been estimated earlier, in (4.12). In particular,

\[
c_2 \sum_{s=s_0}^{s_1-1} 2^{s/2} \nu_s \leq c_3 \sqrt{r} \alpha_r \cdot \log(c_3 r) \leq (\kappa_1/16) \sqrt{n}
\]

for \( c_3 = c_3(L, \beta) \) and as long as \( r \leq c_4(L, \beta) n/\log^4 n \).

To bound the second sum in (4.20) we require another covering estimate.

**Theorem 4.12** There exists an absolute constant \( c \) for which, for every \( z \in S^{n-1} \),

\[
\log N(V_k, ||z||, \varepsilon) \leq c \varepsilon^{-2} k \log(en/k).
\]

**Proof.** The proof of Theorem 4.12 is an outcome of Sudakov's inequality. Fix \( z \in S^{n-1} \) and define the linear operator \( S : \mathbb{R}^n \to \mathbb{R}^n \) by \( S e_i = U^i \). Observe that for \( i \in \lfloor n \rfloor \) and \( t \in \mathbb{R}^n \)

\[
\langle \sqrt{n} D_{W,z} S^* t, e_i \rangle = \sqrt{n} \langle S^* t, D_{W,z} e_i \rangle = \sqrt{n} \langle W_i, z \rangle \langle S^* t, e_i \rangle = \sqrt{n} \langle W_i, z \rangle \langle U^i, t \rangle.
\]

Therefore, \( ||\sqrt{n} D_{W,z} S^* t||_2 = ||t||_2 \) and \( \log N(V_k, ||z||, \varepsilon) = \log N(\sqrt{n} D_{W,z} S^* V_k, \varepsilon B^n_2) \).

Set \( T = \sqrt{n} D_{W,z} S^* V_k \) and let \( G \) be the standard Gaussian vector in \( \mathbb{R}^n \). By Sudakov's inequality (see, e.g., [27]), there is an absolute constant \( c \) for which

\[
c \varepsilon^2 \log N(T, \varepsilon B^n_2) \leq \mathbb{E} \sup_{t \in T} \langle G, t \rangle,
\]

where \( G \) is a standard Gaussian vector in \( \mathbb{R}^n \), and

\[
\mathbb{E} \sup_{t \in T} \langle G, t \rangle = \mathbb{E} \sup_{v \in V_k} \langle G, \sqrt{n} D_{W,z} S^* v \rangle = \sqrt{n} \mathbb{E} \sup_{v \in V_k} \sum_{i=1}^n g_i \langle W_i, z \rangle \langle U^i, v \rangle \equiv \mathbb{E} \left( \sum_{j \leq k} (Z_j^*)^2 \right)^{1/2},
\]

for \( Z_j = \sqrt{n} \sum_{i=1}^n g_i \langle W_i, z \rangle \langle U^i, e_j \rangle \). Each one of the \( Z_j \)'s is a Gaussian variable, and since \( U \)

is a Hadamard type matrix with constant \( \beta \),

\[
\mathbb{E} Z_j^2 = n \sum_{i=1}^n \langle W_i, z \rangle^2 \langle U^i, e_j \rangle^2 \leq \beta^2.
\]

Finally, by Lemma 3.5,

\[
\mathbb{E} \left( \sum_{j=1}^k (Z_j^*)^2 \right)^{1/2} \leq c \beta \sqrt{k \log(en/k)}.
\]
Invoking Theorem 4.12, it follows that for every \( z \in V_r \), \( \varepsilon_s(z) \leq \beta 2^{-s/2} \sqrt{k \log(en/k)} \). Hence,

\[
\sup_{z \in V_r} \varepsilon_s(z) \leq \beta 2^{-s/2} \sqrt{k \log(en/k)},
\]

and the second sum in (4.20) is bounded by

\[
c(L, \beta)(s_1 - s_0) \sqrt{k \log(en/k)} \leq c_1(L, \beta) \alpha_r \sqrt{k \log(en/k)} \leq (\kappa_1/16) \sqrt{n}
\]

provided that

\[
k \leq c_2(L, \beta) \frac{n}{\alpha_r^2 \log \alpha_r}.
\]

This concludes the required estimate on \( H_2 \) and leads to the condition on \( k \).

The final and easiest component is to control \( H_3 \) in (4.15). Indeed,

\[
\|\Gamma^* v \pi_{s_0} x\|_2 \leq \sqrt{n} \|W_{\pi_{s_0}} v\|_\infty \leq \beta \sqrt{r},
\]

and there are at most \( 2^{s_0} \cdot 2^{s_0} = 2^{2s_0+1} \) pairs \( (\pi_{s_0} v, \pi_{s_0} x) \). Since \( \xi \) is isotropic and \( L \)-subgaussian, one has that with probability at least \( 1 - 2 \exp(-u^2/2) \),

\[
|\langle \xi, \Gamma^* \pi_{s_0} v \pi_{s_0} x \rangle| \leq Lu \|\Gamma^* \pi_{s_0} v \pi_{s_0} x\|_2 \leq Lu \beta \sqrt{r}.
\]

Let \( u = 2^{(s_0+2)/2} \), and by the union bound, with probability at least \( 1 - 2 \exp(-c 2^{s_0}) \),

\[
\sup_{v \in V_{r,s_1}, x \in V_k} |\langle \xi, \Gamma^* \pi_{s_0} v \pi_{s_0} x \rangle| \leq 2^{(s_0+2)/2} L \beta \sqrt{r} \leq 2 \cdot \frac{\kappa_1}{8 \kappa_3 L \beta} \sqrt{n} L \beta \sqrt{r} \leq \frac{\kappa_1}{4} \sqrt{n},
\]

because \( \kappa_3, L, \beta \geq 1 \). Taking the union bound over the events in which the bounds for \( H_1, H_2 \) and \( H_3 \) apply, we deduce that

\[
\sup_{v \in V_{r,s_1}} \|\Gamma v \xi\|_k \leq \kappa_1 \sqrt{n}
\]

with probability at least \( 1 - 2 - c_1 n/r - 2 e^{-c_2 2^{s_0}} - 2 \cdot 2^{s_1+1} \geq 1 - 2 - c' 2^{s_0} \) for a suitable constant \( c' \), under condition (4.21) on \( k \). This completes the proof of Lemma 4.10 after relabelling constants.

5 The upper bound on one-sparse vectors

To complete the proof of Theorem 2.5 one has to show that with high probability,

\[
\max_{i \in [n]} \|P_{\Omega} \Gamma e_i \xi\|_2 \leq c \sqrt{\delta n},
\]

for a suitable constant \( c \) and \( \Omega = \{i : \delta_i = 1\} \), see also Theorem 2.3.

**Theorem 5.1** There exist constants \( c_0, c_1 \) and \( c_2 \) that depend only on \( L \) and \( \beta \) for which the following holds. If \( \delta \geq c_0 \frac{\log n}{n} \), then with probability at least \( 1 - 2 \exp(-c_1 \delta n) \),

\[
\max_{i \in [n]} \left( \sum_{j=1}^{n} \delta_j |\langle \Gamma e_i \xi, e_j \rangle|^2 \right)^{1/2} \leq c_2 \sqrt{\delta n}.
\]
The proof of Theorem 5.1 is based on the fact that for every \( i \in [n] \), \( \Gamma_{e_i} \xi \) has a regular coordinate structure, in the sense that is clarified in the following lemma.

**Lemma 5.2** There exist an absolute constant \( c_1 \) and a constant \( c_2 \) that depends on \( \beta \) and \( L \) for which the following holds. Let \( \xi \) be an isotropic, \( L \)-subgaussian random vector and let \( m \in [n] \). Then for every \( i \in [n] \), with probability at least \( 1 - \exp(-c_1 m \log(en/m)) \), \( \Gamma_{e_i} \xi = x + y \), where

\[
\|x\|_2 \leq c_2 \sqrt{m \log(en/m)} \quad \text{and} \quad \max_{i \in [n]} \frac{y_i^*}{\sqrt{\log(en/i)}} \leq c_2.
\]

**Proof.** Let \( i \in [n] \) and set \( z = \Gamma_{e_i} \xi \). Let \( I \) be the (random) set of the \( m \) largest coordinates of \( z \) and define

\[
x = \sum_{j \in I} z_j e_j \quad \text{and} \quad y = \sum_{j \in I^c} z_j e_j.
\]

Observe that \( \|x\|_2 = \|\Gamma_{e_i} \xi\|_{[m]} \). By (3.5) for \( p = m \log(en/m) \), and noting that \( \|W e_i\|_\infty \leq \beta/\sqrt{n} \), one has

\[
\Pr(\|x\|_2 \geq c(L, \beta) \sqrt{m \log(en/m)}) \leq \exp(-m \log(en/m)).
\]

Repeating this argument for \( m \leq \ell \leq n \), it follows that with probability at least

\[
1 - \sum_{\ell = m}^{n} \exp(-\ell \log(en/\ell)) \geq 1 - \exp(-c_1 m \log(en/m)),
\]

for every \( m \leq \ell \leq n \),

\[
z_i^* \leq \frac{1}{\sqrt{\ell}} \|z\|_{[\ell]} \leq 2c(\beta, L) \sqrt{\log(en/\ell)},
\]

and the claim follows.

The coordinate structure of \( \Gamma_{e_i} \xi \) comes into play thanks to a fact from [30].

**Lemma 5.3** Let \( a \in \mathbb{R}^n \), set \( \|a\|_{\psi_1^n} = \max_{1 \leq j \leq n} a_j^*/\log(en/j) \) and put \( 0 < t < \|a\|_{\psi_1^n}/2 \). Then

\[
\Pr\left(\sum_{j=1}^{n} (\delta_j - \delta) a_j > t \delta n\right) \leq 2 \exp(-ct^2 \delta n/\|a\|_{\psi_1^n}^2)
\]

where \( c \) is an absolute constant and \( (\delta_j)_{j=1}^{n} \) are independent selectors with mean \( \delta \).

In particular, if \( a_j = \log(en/j) \) then with probability at least \( 1 - 2 \exp(-c_1 \delta n) \),

\[
\sum_{i=1}^{n} \delta_j \log(en/j) \leq 5\delta n.
\]

**Proof of Theorem 5.1.** Let \( m = \delta n/\log(e/\delta) \) and consider the decomposition of \( \Gamma_{e_i} \xi = x + y \) established in Lemma 5.2. Conditioned on the event from that lemma which holds with probability at least \( 1 - 2 \exp(-c_0 \delta n) \),

\[
\left(\sum_{j=1}^{n} \delta_j x_j^2\right)^{1/2} \leq \left(\sum_{j=1}^{n} x_j^2\right)^{1/2} \leq c_1(L, \beta) \sqrt{m \log(en/m)} \leq c_2(L, \beta) \sqrt{\delta n}.
\]
Then, with probability at least $1 - 2 \exp(-c_3\delta n)$,

$$\sum_{j=1}^{n} \delta_j y_j^2 \leq c_4(L, \beta) \sum_{i=1}^{n} \delta_i \log(en/j) \leq c_5(L, \beta)\delta n.$$  

Hence, with probability at least $1 - 2 \exp(-c_6\delta n)$ with respect to both $\xi$ and $(\delta_j)_{j=1}^{n}$, one has that

$$\left(\sum_{j=1}^{n} \delta_j \langle \Gamma_e, \xi, e_j \rangle^2 \right)^{1/2} \leq c_7(L, \beta)\sqrt{\delta n}.$$  

Recalling that $\delta n \geq c_8 \log n$ for a well chosen $c_8$, it follows from the union bound that with probability at least $1 - 2n \exp(-c_9\delta n) \geq 1 - 2 \exp(-c_6\delta n)$,

$$\max_{i \in [n]} \left(\sum_{j=1}^{n} \delta_j \langle \Gamma_e, \xi, e_j \rangle^2 \right)^{1/2} \leq c_7(L, \beta)\sqrt{\delta n}.$$

$\blacksquare$

### 6 The $\ell_q$-robust null space property for $q > 2$

We will now extend from the $\ell_2$-robustness to $\ell_q$-robustness for general $2 \leq q \leq \infty$. We state our main result for the general type of matrices as used before, i.e., for three Hadamard type matrices $U, W, O$ with constant $\beta$,

$$Av = \Gamma_v \xi = \sqrt{n}UDWvO\xi,$$

where $\xi$ is a random vector with independent mean-zero, variance one, $L$-subgaussian coordinates. Clearly, random circulant matrices fall into this class of random matrices $A$.

**Theorem 6.1** Let $2 \leq q \leq \infty$ and $A$ be a draw of an $n \times n$ random matrix as described above. Let $(\delta_i)_{i \in [n]}$ be a sequence of independent selectors with mean $\delta$, set $\Omega = \{i \in [n] : \delta_i = 1\}$ and put $B = P_{\Omega}A$. For $\nu \in (0, 1)$, set $\alpha_{s,\nu} = \log\left(\frac{s^2}{\nu^2n}\max\left\{\log\left(\frac{\nu^2n}{s}\right), \log(\nu^{-2}s)\right\}\right)$,

$$\zeta(s) = \begin{cases} 
  c_1 & \text{if } s \leq c_2 \sqrt{\frac{n}{\log n}} \\
  c_3\alpha_{s,\nu}^2 \log(\alpha_{s,\nu}) & \text{if } c_2 \sqrt{\frac{n}{\log n}} \leq s \leq c_3 \frac{n}{\log^2(n)}.
\end{cases}$$

and $\rho(s) = \max\{1, \log(e\nu^{-2}r)/\log(en/s)\}$. Assume, for $2 \leq q < \infty$,

$$\delta n \geq c_4\nu^{-2}s \log(en/s)\rho(s)\zeta(s) \max\{q^2, q \log^{1-2/q}(en)\} \quad \text{and} \quad \delta n \geq c_5(q/2)^{-q/2} \log^{q/2}(en)$$

and, for $q = \infty$,

$$\delta n \geq c_7\nu^{-2}s \log(en/s)\rho(s)\zeta(s) \log^2(en).$$

Then with probability at least $1 - n^{-c_6}$ the following holds: For all $x \in \mathbb{R}^n$, all $e \in \mathbb{R}^n$ with $\|e\|_q \leq \eta$ and $y = Bx + e$, the minimizer $x^*$ of

$$\min \|z\|_1 \quad \text{subject to} \quad \|Bz - y\|_q \leq \eta$$

finds $x^*$, such that $\|x - x^*\|_q \leq c_7\nu^{-2}s \log(en/s)\rho(s)\zeta(s) \log^2(en)$ with probability at least $1 - n^{-c_6}$.
satisfies
\[
\|x - x^\#\|_1 \leq \frac{C}{1 - \nu} \sigma_s(x)_1 + \frac{D}{1 - \nu} \sqrt{s} \eta \sqrt{s} \eta \left(\frac{\delta n}{\zeta(s)}\right)^{1/q}
\]
and
\[
\|x - x^\#\|_2 \leq \frac{C}{1 - \nu} \sigma_s(x)_1 + \frac{D}{1 - \nu} \sqrt{s} \eta \sqrt{s} \eta \left(\frac{\delta n}{\zeta(s)}\right)^{1/q},
\]
where we set $1/q = 0$ for $q = \infty$. All constants $c_0, \ldots, c_8$ only depend on $L$ and $\beta$.

Remark.

a) In the theorem above, it suffices to restrict $q$ to the range $[2, \log(en)]$ because for $q \geq \log(en) = q_0$, $\|\cdot\|_q$ and $\|\cdot\|_{q_0}$ are equivalent up to absolute constants.

b) For $q > 2$, the conditions (6.1), (6.2) on the required number of measurements $\delta n$ have more logarithmic factors than the one for $q = 2$. It is presently not clear whether this is an artefact of the proof and one can work with only one logarithmic factor as in the case of matrices with i.i.d. entries [12].

c) The case $q = \infty$ is important for quantized compressive sensing, where one would like to work with consistent reconstruction methods such as $\ell_\infty$-constraint $\ell_1$-minimization,
\[
\min \|z\|_1 \text{ subject to } \|Bz - y\|_\infty \leq \eta.
\]
Our result represents the first near-optimal bound for structured random matrices in this context. We refer to [12] for a detailed discussion of connections to quantized compressive sensing. In the low sparsity case $s \leq \sqrt{c_2 \log n}$, the condition of the required number of samples reads
\[
\delta n \geq c' \nu^{-2} s \log(en/s) \log^2(en).
\]

d) The logarithmic factors of $\log(en)$ may actually be slightly improved to $\log(e\delta n)$, but for convenience we stated the theorem in the above way.

We first provide an extension of Theorem 2.3 in order to reduce the $\ell_q$-null space property to a lower bound of $\|Bx\|_q$ over $x \in V_r$.

**Theorem 6.2** Let $2 \leq q < \infty$. Assume that, for $B \in \mathbb{R}^{m \times n}$,
\[
\inf_{x \in V_r} \|Bx\|_q \geq \tau_q^{-1} \quad \text{and} \quad \max_{j \in [n]} \|Be_j\|_q \leq M_q.
\]
If $r \geq 10(2 + \nu^{-1})^2 \tau_q^2 M_q^2 q \|s\|$, then
\[
\inf_{x \in T_{\nu,s} \cap S^{n-1}} \|Bx\|_q \geq \frac{1}{2 \tau_q}.
\]
Proof. For a vector $z \in \mathbb{R}^n \setminus \{0\}$, we introduce the (discrete) random vector $W$ on $\mathbb{R}^n$ defined via

$$\mathbb{P}(W = \text{sign}(z_j)\|z\|_1 e_j) = \frac{|z_j|}{\|z\|_1}.$$ 

Then $\mathbb{E}W = z$. We take $r$ independent copies $W_1, \ldots, W_r$ of $W$ and define $Z = \frac{1}{r} \sum_{j=1}^r W_j$, so that $\mathbb{E}Z = z$ and $Z/\|Z\|_2 \in V_r$ for every realization of $Z$ so that by assumption $\|BZ\|_q \geq \tau_q^{-1} \|Z\|_2$ and

$$\mathbb{E}\|BZ\|_q^2 \geq \tau_q^{-2} \mathbb{E}\|Z\|_2^2.$$ 

By the triangle inequality,

$$\|Bz\|_q \geq (\mathbb{E}\|BZ\|_q^2)^{1/2} - (\mathbb{E}\|BZ - Bz\|_q^2)^{1/2} \geq \tau_q^{-1} (\mathbb{E}\|Z\|_2^2)^{1/2} - (\mathbb{E}\|BZ - Bz\|_q^2)^{1/2}.$$ 

The expectation in the first term can be computed as

$$\mathbb{E}\|Z\|_2^2 = \frac{1}{r^2} \sum_{i,j=1}^r \mathbb{E}(W_i, W_j) = \frac{1}{r} \mathbb{E}(W, W) + \frac{1}{r^2} \sum_{i \neq j} \mathbb{E}(W_i, W_j) = \frac{\|z\|_2^2}{r} + \frac{r-1}{r} \|z\|_2^2.$$ 

Denoting by $(\epsilon_j)_{j=1}^r$ a Rademacher vector independent of $(W_j)$, symmetrization and Khintchine's inequalities yields

$$\left((\mathbb{E}\|BZ - Bz\|_q^2)^{1/2}\right)^{1/q} \leq \frac{2}{r} \left((\mathbb{E}\|\sum_{j=1}^r (BZ - \mathbb{E}BZ)\|_q^q)^{1/q}\right)^{1/q} \leq \frac{2C\sqrt{q}}{r} \left((\mathbb{E}\|\sum_{k=1}^m \epsilon_j (BW_j)k\|_q^{q/2})^{1/2}\right)^{1/q} = \frac{2C\sqrt{q}}{r} \left(M_p \|z\|_1 \right)^{1/2} \leq 2C\sqrt{q} M_p \|z\|_1^{1/2},$$

where $C = 2^{3/8} e^{-1/2}$ (see e.g. [17, Corollary 8.7]). Hereby, we have also used that $q \geq 2$ and that $\|Be_j\|_q \leq M_q$. Altogether, we obtain

$$\|Bz\|_q \geq \tau_q^{-1} \sqrt{\frac{\|z\|_2^2}{r} + \frac{r-1}{r} \|z\|_2^2} - \frac{2C\sqrt{q} M_q}{\sqrt{r}} \|z\|_1 \geq \frac{\|z\|_2}{\tau_q} - \frac{2C\sqrt{q} M_q}{\sqrt{r}} \|z\|_1.$$ 

Now for $z \in \mathcal{T}_{\nu, s} \cap S^{n-1} \subset (2 + \nu^{-1}) \text{conv } V_s$ we have $\|z\|_1 \leq (2 + \nu^{-1}) \sqrt{s}$, so that

$$\|Bz\|_q \geq \tau_q^{-1} - \frac{2C\sqrt{q} M_q (2 + \nu^{-1}) \sqrt{s}}{\sqrt{r}} \geq \frac{1}{2\tau_q}$$

provided that

$$r \geq \tilde{C} \tau_q^2 (2 + \nu^{-1})^2 M_q^2 q s$$

with $\tilde{C} = 16 C^2 = 16 \cdot 2^{3/4} e^{-1} \approx 9.899 < 10.$
Remark. The same proof strategy can also be applied for $1 \leq q < 2$. However, since $\ell_q$ is of type $q$ for $1 \leq q < 2$, see e.g. [27, Chapter 9], one only obtains $\mathbb{E}\|BZ - Bz\|_q \leq \frac{C_2}{r} M_q r^{1/q} \|z\|_1$ in this case, leading to the condition $r^{1-1/q} \geq C_7 \sqrt{s}$ or
\[
 r \geq C_q s^{2(q-1)}
\]
for $1 < q < 2$, hence, a polynomial scaling of $r$ in $s$ and as a result also polynomial scaling of the number of measurements in $s$ in the end. It is presently not clear whether a different proof strategy may mend this problem.

Let us now consider the lower bound over $V_r$. The following result generalizes Corollary 4.2 and holds for any $1 \leq q < \infty$.

**Theorem 6.3** Let $1 \leq q < \infty$. There exist constants $c_0, \ldots, c_5$ that depend only on $L$ and $\beta$ for which the following holds. Let
\[
\zeta_r = \begin{cases} 
 c_0, & \text{if } r \leq c_1 \sqrt{\frac{n}{\log(c_l n / \kappa_4)}}, \\
 c^2 \log(\alpha_r), & \text{if } c_1 \sqrt{\frac{n}{\log(c_l n / \kappa_4)}} \leq r \leq c_2 \frac{n}{\log^2(n)} 
\end{cases}
\]
and assume that
\[
\delta n \geq c_3 \rho \zeta_r r \log(en/r),
\]
with $\rho$ defined in (3.6). Set $(\delta_i)_{i=1}^l$ to be independent selectors with mean $\delta$ and $\Omega = \{i : \delta_i = 1\}$. Then with probability at least $1 - 2^{-c_4 \min\{2^0, 2^{s_1}\}}$,
\[
\inf_{v \in V_r} \|P_{\Omega} \Gamma_v \|_q \geq c_5 (\delta n / \zeta_r)^{1/q}.
\]

**Proof.** According to Theorem 4.1, with probability at least $1 - 2^{-c_2 \min\{2^0, 2^{s_1}\}}$ we have
\[
\{\Gamma_v \xi : v \in V_r\} \subset T_1 + T_2
\]
with $|T_1| \leq 2^{s_1}$ and $T_2 \subset c_1 n^{-3} B_2^q$. We assume in the following to be in that event. For $v \in V_r$ we write $\Gamma_v \xi = t + y$ with $t \in T_1$ and $y \in T_2$ and conclude that
\[
\left( \sum_{i=1}^n \delta_i |\langle \Gamma_v \xi, e_i \rangle|^q \right)^{1/q} \geq \inf_{t \in T_1} \left( \sum_{i=1}^n \delta_i |t_i|^q \right)^{1/q} - \sup_{y \in T_2} \left( \sum_{i=1}^n \delta_i |y_i|^q \right)^{1/q}
\geq \inf_{t \in T_1} \left( \sum_{i=1}^n \delta_i |y_i|^q \right)^{1/q} - \sup_{y \in T_2} \left( \sum_{i=1}^n \delta_i |y_i|^q \right)^{1/q} - n^{1/2} \sup_{y \in T_2} \|y\|_2
\geq \inf_{t \in T_1} \left( \sum_{i=1}^n \delta_i |y_i|^q \right)^{1/p} - c_1 n^{-1}.
\]
It remains to estimate $\inf_{t \in T_1} (\sum_{i=1}^n \delta_i |y_i|^q)^{1/q}$ from below. Recall from the proof of Theorem 4.1 that $T_1 = V_{r,s_1}$ and for a suitable constant $c$, on the event of probability at least $1 - 2^{-c_1 \min\{2^0, 2^{s_1}\}}$, for every $t = \Gamma_v \xi \in T_1$,
\[
\|t\|_2 \geq c \sqrt{n} \quad \text{and} \quad \|t\|_2 \leq c \sqrt{n} / 2,
\]
(6.5)
see (4.2) as well as (4.8) and Lemma 4.10, where $\theta$ is defined in (4.3) and the constant $c$ only depends on $L, \beta$. Now, for $t \in T_1$, we choose $I = I(t)$ to be the index set corresponding to the $\theta n$ largest absolute coefficients of $t$, and consider $x = P_I t$. Then

$$t_{\theta n}^* \geq \left(\frac{1}{(1-\theta)n} \sum_{i=\theta n}^n (t_i^*)^2\right)^{1/2} = \left(\frac{1}{(1-\theta)n} \left(||t||_2^2 - ||t||_{\theta n}^2\right)\right)^{1/2} \geq \left(\frac{1}{n} (c^2 n - c^2 n/4)\right)^{1/2} = \frac{\sqrt{3c}}{2} = c_1.$$

For $\Omega = \{i : \delta_i = 1\}$ let $K = K(t) = I(t) \cap \Omega$. Then the cardinality of $K$ satisfies $|K| \geq \frac{1}{2} \delta |I| \geq c_2 \theta \delta n$ with probability at least $1 - e^{-c_3 \theta n}$. On this event, $\inf_{t \in T_1} ||P_{\Omega} t||_q \geq c_3 (\theta \delta n)^{1/q}$

By the union over all $t \in T_1$ we conclude that $\inf_{t \in T_1} ||P_{\Omega} t||_q \geq c_3 (\theta \delta n)^{1/q}$ with probability at least

$$1 - 2|T_1| \exp(-c_3 \theta n) = 1 - 2 \cdot 2^{2\gamma_1} \exp(-c_3 \theta n).$$

Hence, by definition of $s_1$, see Definition 3.11, if

$$\delta n \geq C \theta^{-1} \rho \log(en/r)$$

then (6.4) holds with probability at least $1 - 2^{-c_0 2^{\gamma_1}}$, completing the proof by setting $\zeta = \theta^{-1}$.

As the next step, we provide an upper bound for $||P_{\Omega} \Gamma_i \xi||_q$.

**Theorem 6.4** Let $2 \leq q < \infty$. There are constants $c_0, \ldots, c_4 > 0$ such that if $\delta n \geq c_0 \log(n) \max\{1, \log^{q/2}(e/\delta), (q/2)^{-q/2}\}$ then with probability at least $1 - n^{-c_1}$, it holds

$$\max_{i \in [n]} ||P_{\Omega} \Gamma_i \xi||_q \leq c_2 (\delta n)^{1/q} \sqrt{\max\{q, \log(n)^{1-2/q}\}},$$

where $\Omega = \{i \in [n] : \delta_i = 1\}$. Moreover, if $\delta n \geq c_0 \log(en)$, then

$$\max_{i \in [n]} ||P_{\Omega} \Gamma_i \xi||_\infty \leq c_3 \sqrt{\log(en)}, \tag{6.6}$$

with probability at least $1 - n^{-c_4}$.

**Proof.** We proceed similarly to Section 5. For fixed $i \in [n]$, let $z = \Gamma_i \xi$ and, for $m \in [n]$ let $I$ be the random set of $m$ largest absolute coordinates of $z$. We define $x$ and $y$ as in (5.1). As in the proof of Lemma (5.2) we conclude that

$$Pr(||x||_m) \geq c(L, \beta) \sqrt{m \log(en/m)} \leq \exp(-m \log(en/m))$$

34
and

\[
\max_{i \in [n]} \frac{z_i^*}{\sqrt{\log(en/i)}} \leq c_2
\]

with probability at least \(1 - \exp(-c_1 m \log(en/m))\). In conclusion

\[
y_i^* \leq c_2 \sqrt{\log \left( \frac{en}{m + i - 1} \right)}.
\]

Moreover, by (3.5) for \(k = 1\) and \(p = (\alpha + 1) \log(n)\),

\[
\|x\|_\infty = \|z\|_\infty = \|\Gamma_{ei} \xi\|_\infty \leq c(\alpha + 1) \sqrt{\log(en)},
\]

(6.7) with probability at least \(1 - e^{-(\alpha+1) \log(n)} = 1 - n^{-\alpha - 1}\). It follows that

\[
\|x\|_q \leq \|x\|_2^{2/q} \|x\|_\infty^{1-2/q} \leq c_3(\alpha + 1)^{1-2/q} m^{1/q} \log^{1/(2q)} \left( \frac{en}{m} \right) \log^{1/2-1/(2q)} (en)
\]

with probability at least \(1 - n^{-\alpha} - \exp(-c_4 m \log(en/m))\). In order to apply Lemma 5.3 for \(\sum_{j=1}^n \delta_j |y_j|^q\) we note that the sequence \(a_j = \log^{q/2} \left( \frac{en}{m + j - 1} \right)\) satisfies

\[
\sum_{j=1}^n a_j \leq c_5 \left( \frac{q}{2} \right)^{q/2} n
\]

and \(\|a\|_{\psi_1^n} \leq \log^{q/2-1} \left( \frac{en}{m} \right)\). Lemma 5.3 implies that

\[
Pr \left( \sum_{j=1}^n \delta_j |y_j|^q \geq 2c_5(q/2)^{q/2} \delta n \right) \leq 2 \exp \left( -c_6 \frac{\delta n (q/2)^{q/2}}{\log^{q/2-1}(en/m)} \right).
\]

Now choose \(m = \delta n / \log(e/\delta)\). Then

\[
\left( \sum_{j=1}^n \delta_j |x_j|^q \right)^{1/q} \leq \|x\|_q \leq c_3(\alpha + 1)^{1-2/q} (\delta n)^{1/q} \log^{1/2-1/q} (en)
\]

with probability at least \(1 - n^{-\alpha + 1} - \exp(-c_7 \delta n)\) and

\[
\|P_\Omega y\|_q \leq c_8 \sqrt{q/2} (\delta n)^{1/q}
\]

with probability at least \(1 - \exp(-c_9 \delta n (q/2)^{q/2} / \log^{q-2}(e/\delta))\). Taking the union bound over the events for \(x\) and \(y\) and then over \(i \in [n]\) while using that

\[
\delta n \geq c_0 \max\{\log(n), \log^{q/2-1}/2(e/\delta)(q/2)^{-q/2}\}
\]

we obtain

\[
\max_{i \in I} \|P_\Omega \Gamma_{ei} \xi\|_q \leq c_8 \sqrt{\max\{q, \log^{1-2/q}(en)\}} (\delta n)^{1/q}
\]

with probability at least \(1 - n^{-\alpha} - n^{-c_{7}c_{0}+1} - n^{-c_{9}c_{0}+1}\). For suitable \(c_0\) and \(\alpha\) this proves the claim for \(2 \leq q < \infty\). For \(q = \infty\), the claim follows by taking the union over the events for \(i \in [n]\) which ensure (6.7). \(\blacksquare\)
We are now in the position to conclude the proof of the main result of this section.

**Proof of Theorem 6.1.** The constants $M_q$ and $\tau_q$ of Theorem 6.2 can be chosen according Theorems 6.3 and 6.4 as

$$
\tau_q^{-1} = c_1(\delta n/\tau)^{1/q} \quad \text{and} \quad M_q = c_2(\delta n)^{1/q} \sqrt{\max\{q, \log(en)^{1-2/q}\}}
$$

under the condition

$$
\delta n \geq c_3 \rho \zeta r \log(en/r),
$$

where $\zeta_r$ is defined in (6.3). With $r = 10(2 + \nu - 1)^2 c_2^2 M_q^2 q s$, Theorems 6.3–6.4 yield

$$
\inf_{x \in \mathcal{T}_{\nu,s} \cap S_{n-1}} \| P_{\Omega} \Gamma x \xi \|_q \geq c_4(\delta n/\zeta r)^{1/q}
$$

with probability at least $1 - n^{-c_5}$ provided that

$$
\delta n \geq c_6 \nu^{-2} \rho \zeta_s q s \max\{q, \log^{1-2/q}(en)\} \log(en/s).
$$

Since it suffices to consider $2 \leq q \leq \log(en) = q_0$ by equivalence of $\| \cdot \|_{q_0}$ and $\| \cdot \|_q$ for $q > q_0$, the quantity $\zeta_r$ is equivalent to $\zeta(s)$ defined in Theorem 6.1 and $\rho$ turns into $\rho(s)$. By Theorem 2.2, this concludes the proof for the case $q < \infty$.

The case $q = \infty$ is proven in the same way by using (6.6) and observing that for $q_0 = \log(en)$, the norms $\| \cdot \|_{q_0}$ and $\| \cdot \|_\infty$ are equivalent.
