Abstract. The Kazakh Whiteheaded cattle was developed by crossing local breeds with the Hereford breed in Kazakhstan in the 30s of the last century. This breed is adapted to arid conditions of extreme continental climate. The goal of the investigations was the assessment of the genetic structure of the Kazakh Whiteheaded breed based on the genes of calpain (CAPN1) and somatotropic hormone (GH) and analysis of the association of genotypes for these genes with productivity traits. The main argument for this aim is research works illustrated that both genes could affect on meat productivity traits in other breeds of cattle. 352 blood samples from representatives of Kazakh Whiteheaded animals of different sex and age groups were genotyped for the CAPN1 and GH loci. As a result, it was firstly proved that Kazakh Whiteheaded animals, who are CC homozygosis at the CAPN1 locus and VV homozygosis at the GH locus, reliably exceed animals without C and V alleles on the productivity traits such as milk production, average daily body weight gain, and pre-slaughter body weight, slaughter weight, carcass weight, flesh weight, chemical composition and histological characteristics of meat. It was also shown that the frequencies of the desired alleles and genotypes of these loci are rather low - the frequency of the C allele was 0.11–0.17, and the frequency of the CC genotype was 0.03–0.06 in different age and sex groups; the frequency of the V allele was 0.19–0.40, and the frequency of the VV genotype was 0.03–0.31. Thus, planning selection for Kazakh Whiteheaded cattle, it would be useful to take into account the assessment of animal genotypes at the CAPN1 and GH loci to increase the proportion of animals with the desired genotypes.

1 Introduction

Evaluation of animal genotypes by genes associated with the productivity traits is a convenient, accessible and in-demand method to predict the productive qualities of beef cattle at an early age [1-2]. In this regard, studies aimed at identifying the polymorphism of loci associated with the quantitative and qualitative characteristics of muscle and adipose

tissue, and assessing the frequencies of the desired alleles and genotypes in herds are becoming increasingly important [3-5].

Numerous studies have shown the contribution of many genes – *MSTN*, *CAPN*, *CAST*, *GH*, *LEP*, *TG*, *FABP*, *RORC*, *DGAT1*, *SCD* – in meat productivity traits of foreign and domestic breeds [2, 6-15]. The association of calpain gene (*CAPN1*) polymorphism, the product of which controls the weakening of connections between the eye muscle areas and creates conditions for a uniform distribution of intramuscular fat between the fibres, has been demonstrated for many beef cattle breeds [7, 16]. One of the key regulators of animal growth is somatotropic hormone, which also plays an important role in carbohydrate-fat metabolism [17-20]. Therefore, the identification of polymorphism in the genes of calpain *CAPN1* and growth hormone *GH* and the relationship of genotypes for these genes with the meat productivity will improve the selection programs progress.

The goal of our investigation was the estimation of *CAPN1* and *GH* genes polymorphism with certain productivity traits of Kazakh Whiteheaded cattle and identification of desired genotypes for their usage in selection to improve meat production and quality.

## 2 Material and methods

Blood samples of 352 Kazakh Whiteheaded animals from Collective farm «Gigant» (Stavropol’skiy region) were taken. There were sires (n = 35) and dams (n = 160), heifers (n = 64) and young bulls (n = 93). The farm is breeding organization. Mother-stock is kept on the pasture during the whole year. Weaning of calves take place at 240-day age.

The fattening of bulls is carried out according to rations calculated for an average daily gain (at least 1000 g). The bulls are kept loose housing on a non-removable bed; in summer animals were provided with round-the-clock access to out-door, in winter - only during the daylight.

Extraction of DNA from blood samples was carried out with the kit «DIAto mtmDNAPrep» in accordance with the protocol of the company «Isogen» (Russia).

*GH* gene polymorphism was determined by PCR-RFLP using the GenePakPCRCore kits («Isogen») in a volume of 20 μL containing 5 μL of DNA sample, 10 μL of PCR solvent and 1.0 μL of primers each: *GH*-F: 5'-GCT-GCT-CCT-GAG-CCT-TCG-3' and *GH*-R: 5'-GCG-GCG-GCA-CTT-CAT-GAC-CCT-3'. Products of amplification were digested with the restriction enzyme Alu I.

Polymorphism for the *CAPN1* gene was determined on ANK-32 (nucleic acid analyzer) using the «CAPN1» kit, including allele-specific probes: 5'-AGC-AGC-CCA-CCA-TCA-GAG-AAA-3' and 5'-TCA-GCT-GGT-TCG-GCA-GAT-3' («Syntol», Russia).

The work was carried out in the laboratory of immunogenetics and DNA technologies, VNIIOK, "North Caucasian FNATs".

The concentration of fatty acids (FA) in blood plasma was determined by gas-liquid chromatography in the form of methyl esters on a Kristall 200 gas chromatograph with an HP-FFAP 50 m 0.32 mm 0.5 pm capillary column (USA). FA identification was carried out on Sigma and Fluka standards. The quantitative determination of FA was carried out with Chromatek Analyst software.

The blood test included total protein and its fractions, glucose, calcium, phosphorus and magnesium. The analysis was carried out on automatic biochemical analyzers according to the methods described in the department of veterinary medicine at All-Russian Research Institute for Sheep and Goat Breeding (VNIIOK). The milk production of cows was estimated by the live weight of their offspring at the age of 205 days. To assess the conformation of bulls and heifers, 6 animals of each genotype. Measurements of exterior traits were carried out with measuring stick, tape and compasses. Also body conformation
indexes were calculated for each animal. The live weight of bulls at birth and weaning was taken for all genotyped animals (n = 93), at 12 months of age - for 6 animals of each genotype (n = 36). The live weight of heifers was taken at birth, weaning, at 15-month and 18-month age for all genotyped animals (n = 64). The live weight was determined by individual weighing with an electronic scale with an accuracy of 0.1 kg.

To analyze the chemical composition of meat and its histological characteristics, animals were slaughtered at 12-month age according to the standard methods (1977, 1984): three animals of each genotype were used. Analysis of the chemical composition of samples of m. Longissimus dorsi included the determination of moisture, protein and fat (GOST 9793 "Meat and meat products. Methods for the determination of moisture", GOST 25011 "Meat and meat products. Methods for the determination of protein", GOST 23042 "Meat and meat products. Methods for determination of fat"). For histological analysis of eye muscle area, the number and diameter of muscle fibers, and the proportion of muscle and connective tissues were determined. These studies were carried out in accordance with GOST 19496-2013 “Meat and meat products. Method of histological examination”. Allele and genotype frequencies, observed and expected heterozygosity, and the Hardy-Weinberg equilibrium were estimated with the GenAlEx 6.5 program. The results were analyzed statistically with Microsoft Excel. The significance of the differences was calculated by the Student's test with the following significance levels: * – P<0,05; ** – P<0,01; *** – P<0,001.

3 Results and discussion

CAPN1 gene is represented by two alleles C and G, the GH gene is represented also by two alleles V and L. Frequencies of alleles and genotypes for the CAPN1 and GH genes are shown in tables 1 and 2, respectively.

**Table 1.** Frequencies of alleles and genotypes for the CAPN1 gene in Kazakh Whiteheaded cattle of different sex and age groups.

| Sex and age group   | Alleles | Genotypes |
|---------------------|---------|-----------|
|                     | C       | G         | CC | CG | GG   |
| Sires, n=35         | 0,11    | 0,89      | 0,03 | 0,17 | 0,80 |
| Dams, n=106         | 0,14    | 0,86      | 0,04 | 0,19 | 0,77 |
| Young bulls, n=93   | 0,13    | 0,87      | 0,06 | 0,13 | 0,81 |
| Heifers, n=64       | 0,17    | 0,83      | 0,06 | 0,22 | 0,72 |

The frequencies of the CC, CG, and GG genotypes for the CAPN1 gene in all age and sex groups are in accordance with the Hardy-Weinberg equilibrium (chi-square test, p>0.05).

**Table 2.** Frequencies of alleles and genotypes for the GH gene in Kazakh Whiteheaded cattle of different sex and age groups.

| Sex and age group   | Alleles | Genotypes |
|---------------------|---------|-----------|
|                     | V       | L         | VV  | LV | LL  |
| Sires, n=35         | 0,19    | 0,81      | 0,03 | 0,31 | 0,66 |
| Dams, n=106         | 0,30    | 0,70      | 0,16 | 0,28 | 0,56 |
| Young bulls, n=93   | 0,40    | 0,60      | 0,31 | 0,18 | 0,51 |
| Heifers, n=64       | 0,25    | 0,75      | 0,11 | 0,28 | 0,61 |
The distributions of $VV$, $LV$, and $LL$ genotypes for the $GH$ gene among brood bulls and heifers correspond to the Hardy-Weinberg equilibrium (chi-square is 4.13 and 4.00, respectively). Moreover, their distributions of genotypes are the same (chi-square is 2.69 with $p>0.05$). Among dams and young bulls, the Hardy-Weinberg equilibrium are not observed (chi-square is 11.40 and 35.86, respectively). Among dams, there is a significant deficiency of heterozygotes (0.28 compared to the expected frequency of 0.42), among young bulls - also a deficiency, with an expected frequency of $LV$ heterozygotes of 0.48, the observed frequency of heterozygotes is only 0.18.

Thus, we can conclude that genotyping for the $CAPN1$ and $GH$ genes of the Kazakh Whiteheaded breed, polymorphism for these genes was revealed, each gene is represented by two alleles. The low frequency of $C$ ($CAPN1$) and $V$ ($GH$) alleles, which in many studies have been shown as desirable for selection, has been established.

Reproductive traits and milk production of Kazakh Whiteheaded cows of different genotypes for the $CAPN1$ and $GH$ genes. No significant differences in the reproductive traits of cows of different genotypes were found. In total, 159 (99.3%) out of 160 cows calved, 160 calves were received; before weaning, 157 calves were raised (93 bulls and 64 heifers).

The milk production of cows with $CC$ genotypes for the $CAPN1$ gene and $VV$ for the $GH$ gene is significantly higher than that of cows who did not have the desired alleles (table 3). The difference between the live weight of $CC$- and $GG$-dams offspring at the 205-day age was 12.7 kg, or 6.8% ($P<0.05$), the average daily gain of $CC$-dams offspring is significantly higher by 62.8 kg than that of offspring of the $GG$-dams.

Table 3. Milk production characteristics of Kazakh Whiteheaded cows with different genotypes.

| Genotype | Body weight, kg | Average weight, kg |
|----------|-----------------|--------------------|
|          | At birth | 205 days | At weaning (240 days) | Annual daily gain, g |
| $CAPN1$  |          |          |                      |                      |
| $CC$     | 522.6±2.60* | 28.1±0.21 | 202.1±3.5* | 226.0±4.6 | 824.6±1.92* |
| $CG$     | 519.7±1.09 | 27.9±0.18 | 197.7±5.4 | 217.0±6.5 | 787.6±0.72 |
| $GG$     | 516.4±1.19 | 27.6±0.16 | 189.4±5.2 | 210.4±5.2 | 761.8±0.85 |
| $GH$     |          |          |                      |                      |
| $VV$     | 521.5±2.77* | 28.3±0.11 | 201.3±6.5* | 228.0±7.5* | 832.1±1.65* |
| $LV$     | 519.2±2.12 | 27.9±0.18 | 196.9±5.3 | 216.2±4.5 | 784.6±0.92 |
| $LL$     | 518.1±1.97 | 27.6±0.12 | 191.0±4.5 | 209.2±6.1 | 756.7±0.71 |

* $P<0.05$, ** $P<0.01$ при сравнении $CAPN1 – CC$-$GG$; $GH – VV$-$LL$.

The same situation is observed comparing the offspring of cows with the desired $V$ allele of the $GH$ gene and offspring of cows not having this allele. In the offspring of cows with $VV$ and $LV$ genotypes, the average weight at 205 days was 199.1 kg, while in the offspring of cows of the $LL$ genotype - 191.0 kg, or 4.1% less. The average weight of the offspring of $VV$ cows was significantly higher by 10.3 kg, or 5.4% of the average weight of the offspring of cows with the $LL$ genotype, there was a significant difference ($P<0.05$).

At 8- and 12-month age, homozygous $CC$ ($CAPN1$ gene) and $VV$ ($GH$ gene) animals had a larger weight. Thus, bulls with the $CC$ genotype were superior to their peers with the $GG$ genotype by 29.7 kg, or 13.8% ($P<0.01$) at the 8-month age, and by 24.3 kg, or 6.9% ($P<0.05$) at the 12-month age. The weight of $CC$ homozygotes heifers at 8- and 12-month age is 16.2 kg higher, or 8.3% ($P<0.05$), and 22.8 kg, or 7.9% ($P<0.05$), respectively, than that of $GG$ homozygotes. The differences between the weight of $VV$ homozygotes ($GH$ gene) at 8- and 12-month age of young bulls were 34.5 kg (14.6%; $P<0.01$), 24.8 kg (6.9%);
P <0.01), in heifers - 10.2 kg (5.2%; P <0.05), 18.1 kg (6.3%; P <0.05), respectively (tables 4 and 5).

* *P*<0.05, ** *P*<0.01 compared *CAPN1* – CC-GG; *GH* – VV-LL.

Thus, the presence of the desired alleles in the homozygous state promoted higher growth vigor in young bulls and heifers during the studied periods of ontogenesis.

There were no significant differences in body measurements in both young bulls and heifers of different genotypes.

In all examined animals, blood biochemical parameters were within the physiological norm. However, some signs revealed differences between animals of different genotypes. Thus, in young bulls with genotypes CC and VV, which had the number of erythrocytes in the blood 6.42 and 7.2 × 1012 / L, respectively, were significantly differed from the number of red blood cells in young bulls with genotypes GG and LL (P> 0.05). With a higher number of erythrocytes in the blood of young bulls, a higher concentration of hemoglobin was also observed. The number of leukocytes, protein and glucose level in the blood in the CC-*CAPN1* and VV-*GH* calves significantly exceeded these indicators in GG-*CAPN1* and LL-*GH* (P <0.05). There were no significant differences in the level of calcium, phosphorus and magnesium between animals of different genotypes.

The qualitative composition of fatty acids in young bulls of different genotypes was identical. However, in terms of quantitative characteristics, the genotypes were differed. In homozygous CC and VV young bulls, the proportion of unsaturated fatty acids in blood plasma was higher than in homozygous GG and LL animals, respectively, by 6.3% and
7.1%. This also affected the lower values of the lipid metabolism directional index in the CC and VV genotypes - 0.92 and 1.00 versus 1.04 and 1.13 in the GG and LL genotypes. In homozygotes CC and VV and heterozygotes CG and LV, the total amount of lipids and glucose in the blood is lower by an average of 11.2% than in GG- and LL-homozygotes (table 6). The level of cholesterol in the blood of animals of these genotypes is on average 12.8% higher.

Table 6. The metabolites level of energy metabolism in the blood plasma of young Kazakh Whiteheaded bulls of different genotypes.

| Gene | Genotype | Indicators | Amount of fatty acids,% |
|------|----------|------------|-------------------------|
|      |          | Lipids, g/l| Cholesterin, mmol/L     | Glucose, mmol/L |

|      | LL       | 4.82±0.17  | 4.26±0.22               | 52.90         |

* P<0.05, ** P<0.01 compared CAPN1 – CC-GG; GH – VV-LL.

Thus, the obtained data indicate that the intensity of lipid metabolism in young Kazakh Whiteheaded bulls is different in individuals of different genotypes for the CAPN1 and GH genes. It can be assumed that animals with the desired C and V alleles in the homo- and heterozygous state used the energy resources of the blood with greater intensity in the implementation of biosynthetic processes.

Homozygous CC and VV animals have the highest pre-slaughter weight, slaughter weight and carcass weight (table 7). Higher slaughter yield (difference 1.4%) in animals of these genotypes led to superiority in terms of the meat coefficient.

Table 7. Slaughter indicators of Kazakh Whiteheaded young bulls of different genotypes at 12-month age.

| Traits               | Gene/Genotype | CAPN1 | GH |
|----------------------|---------------|-------|----|
|                      | CC            | GG    | VV | LV | LL |
| Pre-slaughter weight | 379.2±2.53**  | 367.9 | 359.9 | 382.7 | 371.8 | 362.9 |
| Slaughter weight     | 221.1±2.58**  | 210.3 | 204.9 | 228.0 | 219.0 | 208.9 |
| Carcass weight       | 210.8±2.07**  | 200.7 | 194.4 | 214.9 | 207.1 | 198.8 |
| Slaughter yield      | 58.3          | 57.1  | 56.9 | 59.6 | 58.9 | 57.6 |
| Meat coefficient     | 4.08          | 4.01  | 3.92 | 4.09 | 4.05 | 4.01 |

* P<0.05, ** P<0.01 compared CAPN1 – CC-GG; GH – VV-LL.

The results indicate a significant effect of the genes of calpain and growth hormone on the slaughter indicators of young bulls of the Kazakh Whiteheaded breed. The presence of C and V alleles is associated with high values of the carcass yield and meat coefficient.
The muscle tissue of animals of CC and VV genotypes for genes CAPN1 and GH was characterized by a higher content of protein and fat, a higher energy value compared to GG and LL genotypes by 0.28–2.13% and 8.7%, respectively (P<0.05, P<0.001) (table 8).

Table 8. Chemical analysis of m. Longissimus dorsi of Kazakh Whiteheaded young bulls of different genotypes.

| Indicator      | Genotype | CAPN1 | GH |
|----------------|----------|-------|----|
|                | CC       | GG    | 0.28% | 2.13% | 8.7% |
|                | CG       | GG    | 0.16% | 0.09% | 0.17% |
|                | GG       | GG    | 0.12% | 0.09% | 0.17% |
|                | VV       | GG    | 0.15% | 0.17% | 0.17% |
|                | LV       | GG    | 0.10% | 0.09% | 0.17% |
|                | LL       | GG    | 0.17% | 0.17% | 0.17% |

Complete characterization of the meat quality can be obtained by histological examinations of the longissimus dorsi muscle. The greatest number of muscle fibers was observed in young bulls of CC and VV genotypes (table 9, fig. 1). They were significantly superior to their peers in all the studied characteristics.

Table 9. Microstructural analysis of m. Longissimus dorsi of Kazakh Whiteheaded young bulls of different genotypes.

| Gene | Genotype | Indicators |
|------|----------|------------|
|      | Number of muscle fibers per mm², pcs. | Muscle fiber diameter, μm | Overall assessment of "marbling", point | Connective tissue, % | Eye muscle area, cm² |
| CC   | 224.07±8.31* | 33.57±0.43** | 31.27±0.82** | 10.60±0.31 | 47.93±3.65 |
| CG   | 219.85±1.96 | 36.25±0.59* | 28.77±0.76** | 11.53±0.44 | 36.04±1.79 |
| GG   | 187.25±3.60 | 37.80±1.93 | 27.75±0.14 | 12.73±0.37** | 28.64±3.03 |
| VV   | 233.18±5.72* | 33.78±0.17** | 29.28±0.41** | 10.93±0.35 | 52.77±0.61** |
| LV   | 199.25±5.41 | 35.89±0.47 | 27.94±0.99* | 12.73±0.59 | 40.92±0.67 |
| LL   | 177.48±1.89 | 40.60±1.41 | 25.43±0.60 | 14.27±0.87** | 31.92±1.51 |

* P<0.05, ** P<0.01 compared CAPN1 – CC-GG; GH – VV-LL.
4 Conclusion

Thus, significant differences have been shown in a number of economically useful traits in the Kazakh Whiteheaded cattle: milk production of cows, body weight, chemical composition of the m. longissimus dorsi, eye muscle area, number and diameter of muscle fibers, proportion of muscle and connective tissue - between animals homozygous for the desired alleles of the CAPN1 genes (allele C) and GH (allele V), with equal production costs for raising animals of different genotypes. This indicates the requirements of selection, aimed at increasing the frequencies of the desired alleles and genotypes, exist. The most valuable animals for breeding selection and further reproduction are those with the genotype where the desired alleles of both genes are present, and especially those individuals where they are in a homozygous state.
