1 Abstract

Derndinger [Der80] and Krupa [Kru90] defined the F–product of a (strongly continuous one–parameter) semigroup (of linear operators) and presented some applications (e.g. to spectral theory of positive operators, cf. [EN00]). Wolff (in [Wol84] and [Wol00]) investigated some kind of nonstandard analogon and applied it to spectral theory of group representations. The question arises in which way these constructions are related.

In this paper we show that the classical and the nonstandard F–product are isomorphic (theorem [4.6]). We also prove a little “classical” corollary ([4.7]).

2 Basic Notation

2.1 Semigroups:

Let $E$ be a (real or complex) Banachspace. We denote the norm of an element $f$ of $E$ by $|f|$. $L(E)$ is the set of bounded linear functions from $E$ to $E$. The elements of $L(E)$ are called bounded linear operators, and the norm of an operator $A$ is denoted by $\|A\|$. A one–parameter semigroup of bounded linear operators (or semigroup, for short) is a function $T : \mathbb{R}_0^+ \to L(E)$ such that $T(0) = \text{Id}_E$ and $T(t_1 + t_2) = T(t_1) \circ T(t_2)$. A semigroup $T$ is called strongly continuous (or continuous, for short), if for all $f \in E$, $\lim_{t \to 0} |T(t)f - f| = 0$ (i.e. $\lim_{t \to 0} T(t) = \text{Id}_E$ in the strong topology). $T$ is called uniformly continuous, if $\lim_{t \to 0} \|T(t) - \text{Id}_E\| = 0$ (i.e. $\lim_{t \to 0} T(t) = \text{Id}_E$ in the topology induced by the operator–norm).

For a continuous semigroup $T$ and $f \in E$ we define $A(f) := \lim_{h \to 0} \frac{1}{h}(T(h)f - f)$, if this limit exists (in $E$). $D(A)$ is the set of $f \in E$ such that $A(f)$ exists. $A$ is called the Generator of $T$.

More about the (classical) theory of continuous semigroups can be found in the textbook [EN00]. We will only need the following results:

Lemma 2.1. 1. For every continuous semigroup $T$ there exist constants $M \geq 1$, $\omega \in \mathbb{R}$ such that for all $t \in \mathbb{R}_0^+$: $\|T(t)\| \leq Me^{\omega t}$.

2. $D(A)$ is a dense linear subspace of $E$, and $A$ is a closed linear operator (i.e. the graph of $A$ is a closed subset of $E \times E$).

3. $D(A) = E$ if and only if $T(t)$ is uniformly continuous.

4. If $f \in D(A)$ and $h > 0$, then $|T(h)f - f| \leq h \cdot |A(f)| \cdot \sup_{s \leq h} \|T(s)\|$.

5. If $f \in D(A)$ and $h > 0$, then $|\frac{1}{h}T(h)f - A(f)| \leq \sup_{s \leq h}(|T(s)A(f) - A(f)|)$.

6. For any $\bar{f}$ and $h > 0$ there is a $f \in D(A)$ such that $A(f) = \frac{1}{h}(\frac{d}{d}f - f)$ and $|\bar{f} - f| \leq \sup_{s \leq h}(|T(s)\bar{f} - \bar{f}|)$.

Remark: The last three items of the lemma follow from the following two facts:

If $f \in D(A)$ and $t > 0$, then $T(t)f - f = \int_0^t T(s)Afds$.

For all $f \in E$ and $t > 0$, $\int_0^t T(s)fds$ is in $D(A)$, and $A(\int_0^t T(s)fds) = T(t)f - f$.

(The integral is defined as the limit of the Riemann–sums.)
A nonstandard universe $x$ treat the elements of $V$ is a base–set, i.e. $X$ and $Y$.

Note that the transfer principle is similar to the well–known Łoś’ theorem for ultraproduct–constructions. However, $V$ since otherwise Łoś’ theorem would apply to $X$.

Let $f$ uniform continuous: for example, let $t > 0$.

For all $T$ we present the concept of nonstandard extensions following [CK90].

Our basic example for such a semigroup is the following:

Example 2.2. $C^b$ is the (real) Banachspace of uniformly continuous, bounded functions from $\mathbb{R}$ to $\mathbb{R}$ (with the sup–norm, denoted by $\| \cdot \|_\infty$). $T$ is the translation semigroup, defined by $T(t)f(x) := f(x + t)$.

Then $T$ is continuous (since each $f \in C^b$ is uniformly continuous), but $T$ is not uniformly continuous: for example, let $f_k(x) = \sin(kx)$.

For all $t > 0$ there is a $k$ such that $|T(t)f_k - f_k| > 1$, i.e. $\|T(t) - \text{Id}_E\| > 1$. $f$ is in $D(A)$ if and only if $f'$ exists and is element of $E$. In this case, $A(f) = f'$.

2.2 Robinsonian (nonstandard) analysis:

We present the concept of nonstandard extensions following [CK90].

Let $X$ be a set. $P(X)$ denotes the set of all subsets of $X$. $V_0(X) = X$, $V_{n+1}(X) = V_n(X) \cup P(V_n(X))$, $V(X) = \bigcup_{n \in \omega} V_n(X)$. We assume that (a suitable copy of) $\mathbb{N}$ exists in $X$, and that all vector spaces we are interested in are subsets of $X$. So all sets of numbers, subspaces of $E$ etc are in $V(X)$. For technical reasons, we want to treat the elements of $X$ as urelements, i.e. we want to avoid that for some $y \in V(X)$ and $x \in X$, $y \in x$. We can do that by assuming (without loss of generality) that $X$ is a base–set, i.e. $X$ does not contain the empty set and $x \cap V(X)$ is empty for all $x \in X$.

A nonstandard universe is a triple $\langle V(X), V(Y),^* : V(X) \to V(Y) \rangle$ such that:

- $X$ and $Y$ are infinite base–sets, $X \subset Y$, $^*X = Y$, for all $x \in X$, $^*x = x$.
- (non–triviality) for every infinite subset $A$ of $X$: $A \subsetneq {}^*A$.
- (transfer principle) if $\varphi(x_1, \ldots, x_n)$ is a $\Sigma_0$ formula and $a_1, \ldots, a_n \in V(X)$, then $V(X) \models \varphi(a_1, \ldots, a_n)$ iff $V(Y) \models \varphi(^*a_1, \ldots, ^*a_n)$

$\Sigma_0$ formulas are first order formulas $\varphi$ (in the Language $\{ \in \}$) such that only quantifiers of the form $\forall x \in y$ and $\exists x \in y$ occur in $\varphi$.

Note that the transfer principle is similar to the well–known Łoś’ theorem for ultraproduct–constructions. However, $V(Y)$ cannot be an ultrapower of $V(X)$, since otherwise Łoś’ theorem would apply to all first order formulas, including the formula “for all natural numbers $n$, there is a decreasing $\in$–chain of length $n$". This sentence cannot be true in $(V(Y), ^*)$, since $\in$ is well–founded and $V(Y)$ has nonstandard natural numbers. However, $Y$ can be an ultrapower of $X$, and this specific kind of nonstandard extension is the most important one in our context:

Let $U$ be a countably incomplete ultrafilter over a set $I$ (i.e. there is a countable family $A_n$ of elements of $U$ such that $\bigcap A_n \notin U$). Let $Y$ be the ultrapower of $X$ with respect to $U$. (Without loss of generality we can assume that $X$ and $Y$ are base–sets). Then $V(Y)$ can be made a nonstandard extension of $V(X)$ in a way that the map $^*$ restricted to $X$ is the usual ultrapower injection, i.e. $^*x$ is the equivalence class of the constant function $c_x$. Non–triviality follows from the fact
that $\mathcal{U}$ is countably incomplete, and the transfer principle is proved similar to Los’ theorem.

Nonstandard extension obtained in this way are called bounded ultrapowers.

In any nonstandard extension there are infinite numbers: The sets $^*\mathbb{N} \supseteq \mathbb{N}$ and $^*\mathbb{R} \supseteq \mathbb{R}$ are called the nonstandard natural and real numbers. Sometimes we will call $\mathbb{N}$ and $\mathbb{R}$ the standard natural (or real) numbers to emphasis the difference.

A nonstandard number $r$ is called finite if there is a standard natural number $n$ such that $|r| < n$ (in $V(^*X)$). So a natural number is finite iff it is standard. A nonstandard number that is not finite is called infinite. A nonstandard real $r$ is called infinitesimal if $r = 0$ or $r \neq 0$ and $\frac{1}{r}$ is infinite.

Let $r, s \in ^*\mathbb{R}$. $r \approx s$ stands for “$r - s$ is infinitesimal”. For each finite $r \in ^*\mathbb{R}$ there is a unique real number $r'$ such that $r' \approx r$. This $r'$ is denoted by $\text{std}(r)$.

Similar notation will be introduced for elements of nonstandard normed vectorspaces (on page 5).

The following notions are central in nonstandard analysis:

- $y \in V(Y)$ is called standard if there is a $x \in V(X)$ such that $y = ^*x$.
- $y \in V(Y)$ is called internal if there is a $x \in V(X)$ such that $y \in ^*x$.
- $y \in V(Y)$ is called external if $y$ is not internal.

Note that for $y \in Y$, $y$ is standard iff $y \in X$, so the notation is compatible with our use of standard natural (or real) numbers.

An example of an internal set that is not standard is the set of all nonstandard natural numbers less than some $m$, where $m$ is infinite.

If $A, B$ are internal (or standard), then so are $A \cup B$, $A \setminus B$, etc.

The set of all infinite natural numbers in not internal. This is a special case of the so-called spillover principle:

**Theorem 2.3.** (spillover principle) Let $A$ be internal.

- $A$ contains arbitrary large finite (i.e. standard) natural numbers iff $A$ contains arbitrary small infinite natural numbers.
- $A$ contains arbitrary small positive standard reals iff $A$ contains arbitrary large positive infinitesimals.

It is important to note that $A$ just has to be internal, it is not necessary that $A$ is internal.

If $A$ is a set in $V(X)$, then $P^\text{fin}(A)$, the set of all finite subsets of $A$, is in $V(X)$ as well, and is mapped to $^*P^\text{fin}(A) \in V(Y)$. If $A$ was infinite, this set will contain more elements than just the sets $^*B$, where $B \subset A$ finite. These new elements are called hyperfinite (note that they do not have to be finite). So a set $B$ in $V(Y)$ is called hyperfinite, if there is some $A \in V(X)$ such that $B \in ^*P^\text{fin}(A)$.

The example above, $\{ n \in ^*\mathbb{N} : n < m \}$, is an example of an infinite, hyperfinite, internal set. It is easy to see that all hyperfinite sets are internal.

For the examples [3],[9] and [1],[3] we use a nonstandard extension such that the standard reals are a subset of a hyperfinite set.

More general, we call a nonstandard extension $V(Y)$ an enlargement if for every $A \in V(X) \setminus X$ there is a hyperfinite $B \in V(Y)$ such that $\{ ^*a : a \in A \} \subset B$.

It is provable (using the Axiom of Choice, of course) that for any base–set $X$ there is a index set $I$ and an ultrafilter $\mathcal{U}$ over $I$ such that the bounded ultrapower with respect to $\mathcal{U}$ is an enlargement. (For details, see e.g. [CK90]. The outline of the proof is as follows:

3
1. for every $\kappa$, there are $\kappa$–good filters
2. $\kappa$–good filters result in $\kappa$–saturated extensions
3. Given $X$, let $\kappa_X$ be the cardinality of $V(X)$. Then $\kappa_X$–saturated extensions are enlargements.

The only consequence of the concept of enlargement that we are going to use is the following:

**Lemma 2.4.** Let $V(\ast X)$ be a nonstandard enlargement of the universe. Then there is a (infinite) nonstandard natural number $k$ such that $\sin(kt)$ is infinitesimal for all standard reals $t$.

**Proof.** The standard reals $\mathbb{R}$ are a subset of some hyperfinite set $A$ of nonstandard reals.

It is a well–known (classical) fact that for every finite set of reals $A$, and every positive $\varepsilon$ there is a natural number $k$ such that for all $t \in A$, $\sin(kt) < \varepsilon$. So by transfer of the classical fact, setting $\varepsilon$ infinitesimal, we get a $k \in \ast \mathbb{N}$ such that for all $t \in \mathbb{R}$, $\sin(kt)$ is infinitesimal. \qed

When we compare nonstandard constructions with classical constructions, we will assume that our nonstandard extension is a bounded ultrapower (generated by the same ultrafilter) — otherwise it isn’t clear what the classical analogon should be. It should be noted that there are nonstandard universes which are not bounded ultrapowers: An ultrapower is always $\aleph_1$–saturated (since all filters are $\aleph_1$–good), but the union of a countable elementary chain of ultrapowers is not (see [CK90, page 290, 4.4.29]). However, every extension can be seen as limit of ultrapowers (see [CK90]), and in practice, authors often restrict their attention to the case of ultrapowers (see e.g. [HL85, page 88]).

### 3 Ultrapowers and Nonstandard–Hulls

#### 3.1 Constructions without Semigroups

Let $E$ be a normed vectorspace, $I$ an arbitrary set. We define $l^\infty(E)$ to be the space of all bounded $E$–valued $I$–sequences with the sup–norm (denoted by $\|\cdot\|_\infty$). Then $l^\infty(E)$ is a normed vectorspace. Note that $I$ does not have to be countable, it can be of any cardinality.

Assume $\mathcal{U}$ is a filter over $I$ (not necessarily an ultrafilter). As in [Der80], we define $c_\mathcal{U}$ to be the set of sequences $\langle f_i \rangle$ such that for all $\varepsilon$ there is a set $J \subseteq I$ such that $J \in \mathcal{U}$ and $|f_i| < \varepsilon$ for all $i \in J$.

**Lemma 3.1.** $|y + c_\mathcal{U}| := \inf \{|x| : x \in y + c_\mathcal{U}\}$ is a norm on $l^\infty(E)/c_\mathcal{U}$, and $E$ is a Banachspace if and only if $l^\infty(E)$ is a Banachspace. If $E$ is a Banachspace, then $l^\infty(E)/c_\mathcal{U}$ is a Banachspace as well.

**Proof.** If $E$ is a Banachspace, then so is $l^\infty(E)$ (since Cauchy–sequences converge pointwise). Clearly, $c_\mathcal{U}$ is a closed subspace of $l^\infty(E)$. And any normed (and complete) vectorspace can be factored by a closed subspace, resulting in a normed (and complete, resp.) vectorspace. If $l^\infty(E)$ is complete, then clearly so is $E$ (otherwise take any non–converging Cauchy–sequence $f_i$ in $E$, and map it to the sequence $g_i = (f_i, 0, 0, \ldots)$ in $l^\infty(E)$). \qed

Note that $l^\infty(E)/c_\mathcal{U}$ can be a Banachspace although $E$ (and therefore $l^\infty(E)$) is not, see the remark after theorem 3.3.
The corresponding nonstandard construction is the following: Let \( V(\ast X) \) be a nonstandard universe, and \( E \subset X \) a normed vectorspace. Then \( \ast E \) is a nonstandard normed vectorspace, and a standard vectorspace (without canonical norm).

We define the finite part of \( \ast E \), denoted by \( \text{fin} \ast E \), to consist of all elements \( f \) of \( \ast E \) such that \( |f| \) is finite. \( f \approx g \) means that \( |f| = |g| \) is infinitesimal. The infinitesimal part of \( \ast E \), denoted by \( E_0 \), consists of all \( f \) such that \( |f| \) is infinitesimal, i.e. \( f \approx 0 \). Clearly, \( E_0 \) is a (standard) sub–vectorspace of \( \text{fin} \ast E \).

\( \tilde{E} \) is the quotient of \( \text{fin} \ast E \) and \( E_0 \), and the canonical quotient map \( \text{fin} \ast E \to \tilde{E} \) is denoted by \( \gamma \), i.e. the quotient–class of \( f \) is \( \tilde{f} \), and \( f \) is called representant of \( \tilde{f} \).

\( \tilde{E} \) is a normed vectorspace with the norm \( \| \tilde{f} \| := \text{std}(|f|) \), where \( f \) is any representant of \( \tilde{f} \) and \( \text{std}(r) \) is the standard part of a finite nonstandard real \( r \). Of course, the vectorspace–operations are defined by \( \tilde{f} + \tilde{g} := \tilde{f} + g \) and \( \alpha \tilde{f} := \alpha \tilde{f} \).

**Lemma 3.2.** If \( V(\ast X) \) is a bounded ultrapower, then \( \tilde{E} \) is a Banachspace.

A proof can be found e.g. in [Lin88, page 59], noting that a bounded ultrapower is \( \mathbb{N}_1 \)–good and therefore the extension will be \( \mathbb{N}_1 \)–saturated.

A straightforward calculation proves that for an ultrafilter \( U \), the F–product and the nonstandard hull are the same:

**Theorem 3.3.** Let \( U \) be an ultrafilter, \( V(\ast X) \) the corresponding bounded ultrapower. Then \( i : l^\infty(E)/c_0 \to \tilde{E} \) defined by \( i(f + c_0) = \tilde{f} \) is an isomorphism.

So if \( U \) is a countably incomplete ultrafilter, then \( l^\infty(E)/c_0 \) is a Banachspace (according to lemma 3.2), regardless of whether \( E \) was a Banachspace or not.

### 3.2 Classical Constructions for Semigroups

**The Maximal Continuous Subspace:** Assume, \( T(t) \) is a semigroup on \( E \) (not necessarily continuous), and assume \( M, \omega \) are such that \( \|T(t)\| \leq Me^{\omega t} \) (for continuous semigroups, such \( M, \omega \) always exist, according to lemma 2.1).

Define \( (E)^{T-\text{max}} := \{ f \in E : \lim_{t \to 0} |T(t)f - f| = 0 \} \).

A subspace \( F \) of \( E \) is called \( T \)–invariant, if \( T(t)f \in F \) for all \( f \in F \) and \( t \in \mathbb{R}^+ \).

**Lemma 3.4.** \( (E)^{T-\text{max}} \) is a closed \( T \)–invariant subspace of \( E \), and it is maximal in the family of subspaces \( F \) of \( E \) such that \( T(t) \) restricted to \( F \) is continuous.

**Proof.**
- closed: Assume \( f_i, f \in E \) such that \( f_n \to f \), and choose an \( \varepsilon > 0 \).
  Let \( n \) be such that \( |f_n - f| < \min(\frac{\varepsilon}{2M}, \frac{\delta}{3}) \). \( |T(t)f - f| \leq |T(t)f - T(t)f_n| + |T(t)f_n - f_n| + |f_n - f| \). If \( t < \delta \) (for a suitable \( \delta \)) then \( \|T(t)\| < 2M \) and \( |T(t)f_n - f_n| < \frac{\varepsilon}{3} \) (since \( f_n \in (E)^{T-\text{max}} \)), so \( |T(t)f - f| \leq 2M \frac{\varepsilon}{6M} + \frac{\varepsilon}{3} + \frac{\varepsilon}{3} \leq \varepsilon \).
- invariant: Assume \( f \in (E)^{T-\text{max}} \), \( s \in \mathbb{R}_0^+ \). Then \( |T(t)(T(s)f) - T(s)f| = |T(s)(T(t)(f) - f)| \leq \|T(s)\|\|T(t)f - f\| \).
- maximal: If \( T \) is continuous on \( F \) and \( f \in F \), then by definition \( f \) is an element of \( (E)^{T-\text{max}} \).

\[ \square \]

Remark: This definition and lemma just isolate a part of the proof that is given e.g. in [Der80] for corollary 3.3. This way we don’t have to repeat the same argument again (e.g. for lemma 3.2).
\(m^T\): Let \(T(t)\) be continuous, \(\|T(t)\| \leq Me^{\omega t}\), and let \(\langle f_i \rangle\) be an element of \(l^\infty(E)\). Define \(\tilde{T}(t)(\langle f_i \rangle) = (T(t)f_i)\).

Since \(T(t)\) is bounded, \(\tilde{T}(t)(\langle f_i \rangle) \in l^\infty(E)\) for all \(\langle f_i \rangle \in l^\infty(E)\) and \(t \geq 0\). It is clear that \(\tilde{T}\) defines a semigroup on \(l^\infty(E)\). Also, \(\|\tilde{T}(t)\| \leq Me^{\omega t}\).

But in general \(\tilde{T}\) will not be continuous on \(l^\infty(E)\): Let \(T\) be the translation semigroup on \(C^b\), as in [2,2]. \(I = \omega, \mathcal{U}\) a free ultrafilter over \(\omega\), and \(f_k(x) = \sin(kx) \in C^b\). Then \(f = \langle f_k \rangle \in l^\infty(E)\), but \(\tilde{T}(t)f - f\) does not converge.

On can show rather easily that \(\tilde{T}\) is continuous on \(l^\infty(E)\) if and only if \(T\) is uniformly continuous on \(E\) (assuming of course that the index set \(I\) is infinite).

We define \(m^T\) to be the maximal continuous subspace of \(l^\infty(E)\) with respect to \(T\).

**Corollary 3.5.** \(m^T\) is a closed, \(\tilde{T}\)-invariant subspace of \(l^\infty(E)\).

**F-Product of a semigroup:** As we have seen, if \(T\) is a semigroup defined on \(E\), under certain assumptions \(T\) can be extended to a (not necessarily continuous) semigroup \(\tilde{T}\) on \(l^\infty(E)\). Assume \(\langle f_i \rangle \in \mathcal{C}_U\) (i.e., for all \(\varepsilon \in \mathbb{R}^+, |f_i| < \varepsilon\) holds on a filter-set). \(\tilde{T}(t)(\langle f_i \rangle) \in \mathcal{C}_U\) for all \(t \geq 0\), since \(\tilde{T}(t)\) is a bounded operator. This means that \(\mathcal{C}_U\) is \(\tilde{T}\)-invariant, and that we can define \(\tilde{T}\) on \(l^\infty(E)/\mathcal{C}_U\). Of course, \(\tilde{T}\) is a semigroup on \(l^\infty(E)/\mathcal{C}_U\) and (generally not continuous).

\(\mathcal{C}_U\) is not a subspace of \(m^T\). (For example, any \(\langle f_i \rangle\) such that \(f_i = 0\) on a filter-set is in \(\mathcal{C}_U\), but not necessarily in \(m^T\).) However, it is easy to see that \(\mathcal{C}_U \cap m^T\) is a closed subset of \(m^T\), and \(m^T/\mathcal{C}_U \cap m^T\) is a subspace of \(l^\infty(E)/\mathcal{C}_U\).

To be more exact:

**Lemma 3.6.** \(\phi: \mathcal{C}_U \cap m^T \to l^\infty(E)/\mathcal{C}_U\) defined by \(\phi(\langle f_i \rangle + \mathcal{C}_U \cap m^T) = \langle f_i \rangle + \mathcal{C}_U\) is a (well-defined) injective isometry.

**Proof.** See [Kru90, page 163]. \(\square\)

**Lemma 3.7.** \(m^T/\mathcal{C}_U \cap m^T\) is a closed, \(\tilde{T}\)-invariant subspace of \(l^\infty(E)/\mathcal{C}_U\).

\(\tilde{T}\) restricted to \(m^T/\mathcal{C}_U \cap m^T\) is continuous.

**Proof.** The quotient \(m^T/\mathcal{C}_U \cap m^T\) of the Banachspace \(m^T\) is a Banachspace, and so is its isometric image. The rest is clear. \(\square\)

In general, \(m^T/\mathcal{C}_U \cap m^T\) is not the maximal continuous subspace of \(l^\infty(E)/\mathcal{C}_U\). This is shown in example [3,9] (using that \(m^T/\mathcal{C}_U \cap m^T\) corresponds to \(E\), see lemma [3,11]).

### 3.3 Nonstandard Constructions for Semigroups

Let \(V(\ast X)\) be a nonstandard universe, \(E \subset X\) a Banachspace.

Assume \(A: E \rightarrow E\) is a continuous linear operator, and \(f\) an element of \(\text{fin} \ast E\), \(g\) an element of \(E_0\) (the finite and infinitesimal parts of the nonstandard vector space \(\ast E\), resp.). Then \(\ast Af\) (and \(\ast Ag\)) are again finite (and infinitesimal, resp.). Therefore \(A\) defines a bounded linear operator \(\hat{A}: \hat{E} \rightarrow \hat{E}\) by \(\hat{A}(\hat{f}) = \hat{A}f\). (If \(A\) is not bounded, then generally \(\hat{A}\) cannot be defined in a canonical way.)

If \(T\) is a semigroup, then for all positive reals \(t\), \(T(t)\) is continuous, and \(\tilde{T}(t) := \tilde{T}(t)\) is a semigroup on \(\hat{E}\).

If \(\|T(t)\| < Me^{\omega t}\) (this is always the case if \(T\) is continuous), then an alternative way to define \(\tilde{T}\) is the following: \(\ast T\) is a nonstandard semigroup on \(\ast E\). If \(t\) is a positive, finite nonstandard real, then \(\|\ast T(t)\| < Me^{\omega t}\), so we get: If \(f \in \ast E\) is
Assume \( T \) is continuous, i.e. for all \( f \) in \( E \) and all \( \varepsilon > 0 \) there is a \( \delta > 0 \) such that \( |T(t)f - f| < \varepsilon \) for all \( t < \delta \). We apply the transfer principle to this sentence, and get: For all \( f \in \!*E \) and all \( \varepsilon \in \!*\mathbb{R}^+ \), there is a \( \delta \in \!*\mathbb{R}^+ \) such that \( |\!^*T(t)f - f| < \varepsilon \) for all positive reals \( t < \delta \): However, if \( \varepsilon > 0 \) is a standard real, then it is not guaranteed that \( \delta > 0 \) can be chosen to be standard as well (\( \delta \) could be infinitesimal).

We define two subspaces of \( \text{fin} \!*E \) (the finite part of \( \!*E \)): \( E_T \) consists of all the vectors \( f \) with the following property: If \( \varepsilon > 0 \) is standard, then there is a standard \( \delta > 0 \) such that \( |\!^*T(t)f - f| < \varepsilon \) for all nonstandard \( t < \delta \). \( E_{\max} \) consists of all \( f \) satisfying the same condition for standard \( t < \delta \) only. I.e. a finite \( f \in \!*E \) is in \( E_{\max} \) iff for all \( \varepsilon \in \!*\mathbb{R}^+ \) there is a \( \delta \in \!*\mathbb{R}^+ \) such that \( |\!^*T(t)f - f| < \varepsilon \) for all positive standard reals \( t < \delta \).

It is easy to see that a finite \( f \in \!*E \) is in \( E_T \) iff for all positive infinitesimal \( t \), \( |\!^*T(t)f - f| \) is infinitesimal.

Clearly, \( E_0 \) is a subspace of \( E_T \), which is in turn a subspace of \( E_{\max} \). So, if \( f \in E_T \) (or \( E_{\max} \)) and \( f \approx g \), then \( g \in E_T \) (or \( E_{\max} \), resp.), and we can define the quotient spaces \( \widehat{E_T} = E_T/E_0 \) and \( \widehat{E_{\max}} = E_{\max}/E_0 \). Remember that (other then \( \text{fin} \!*E \)), \( E_T \) is a (canonically) normed vectorspace.

**Lemma 3.8.**

1. \( \widehat{E_{\max}} \) is the maximal continuous subspace of \( \widehat{E} \) with respect to \( \widehat{T} \).
2. \( \widehat{E_{\max}} \) is a closed, \( \widehat{T} \)-invariant subspace of \( \widehat{E} \).
3. \( \widehat{E_T} \) is a closed, \( \widehat{T} \)-invariant subspace of \( \widehat{E_{\max}} \).

**Proof.**

1. Assume, \( \lim_{t \to 0} |\!^*T(t)\hat{f} - \hat{f}| = 0 \), and fix \( \varepsilon \in \!*\mathbb{R}^+ \). Then there is a \( \delta \in \!*\mathbb{R}^+ \) such that for all positive reals \( t < \delta \), \( |\!^*T(t)\hat{f} - \hat{f}| < \frac{\varepsilon}{2} \). Assume that \( f \) is a representant of the quotient \( \hat{f} \), and that \( t < \delta \). Then \( \text{std}(\!^*T(t)f - f) < \frac{\varepsilon}{2} \), and therefore \( |\!^*T(t)f - f| < \varepsilon \) in \( \!^*\mathbb{R} \), so \( f \in E_{\max} \) and \( \hat{f} \in \widehat{E_{\max}} \).

2. this follows from 1. and lemma 3.2

3. Assume that \( \hat{f}_n \in \widehat{E_T} \), and \( \hat{f}_n \to \hat{f} \) in \( E_T \). Let \( f_n \) and \( f \) be representatives of \( \hat{f}_n \) and \( \hat{f} \), resp. Assume \( h \) is a positive infinitesimal. Then \( |\!^*T(h)f - f| \leq |\!^*T(h)f - \!^*T(h)f_n| + |\!^*T(h)f_n - f_n| + |f_n - f| \), which is smaller than every positive standard \( \varepsilon \), since \( |f_n - f| \) gets arbitrary small, \( |\!^*T(h)f - f| \leq \|\!^*T(h)||f - f_n| \), and \( |\!^*T(h)f_n - f_n| \) is infinitesimal.

To show the invariance, assume that \( \hat{f} \in \widehat{E_T} \), and let \( f \in E_T \) be a representant. Let \( t \) be a positive standard real, and \( h \) is a positive infinitesimal. \( |\!^*T(h)\!^*T(t)f - \!^*T(t)f| \leq \|\!^*T(t)||\!^*T(h)f - f| \), which is infinitesimal. So \( \!^*T(t)f \in E_T \), and therefore \( \widehat{T(t)\hat{f}} \in \widehat{E_T} \).

Remark: In [Wo00], an alternative way to construct \( E_T \) is presented. Theorem 4.6.1 there corresponds to our 3.2

In general, \( \widehat{E_T} \) is a proper subset of \( \widehat{E_{\max}} \) (or equivalently: \( E_T \) is a proper subset of \( E_{\max} \)). To see this, we bring an example similar to [Kru90, page 165] or [Wo84, page 209]:

7
**Example 3.9.** Let $T$ be the translation semigroup on $C^b$ (as in example 222), \( V(\star X) \) a enlargement, \( k \) such that \( \sin(kt) \) is infinitesimal for all \( t \in \mathbb{R} \) (see lemma 24). Define the element \( f \) of \( *C^b \) by \( f(x) = \sin(kx) \). Then \( |f| = 1 \), and \( f \) is an element of \( E_{\text{max}} \), but not of \( E_T \).

**Proof.** To see that \( f \in E_{\text{max}} \), it is enough to show that for all positive (standard) reals \( t \), \( |T(t)f - f| \) is infinitesimal. For any standard reals \( t \), \( \sin(k(x + t)) - \sin(kx) = \sin(kx)(\cos(kt) - 1) + \sin(kt)\cos(kx) \). \( \sin(kx) \) and \( \cos(kx) \) are finite, and \( \sin(kt) \) and \( \cos(kt) - 1 = (\sqrt{1 - \sin^2(kt)} - 1) \) are infinitesimal. Therefore \( |T(t)f - f| = \|\sin(k(x + t)) - \sin(kx)\|_\infty = \|\sin(x + 1) - \sin(x)\|_\infty \) is infinitesimal.

To see that \( f \notin E_T \), it is enough to note that \( h := \frac{1}{k} \) is infinitesimal, but \( |T(h)f - f| = \|\sin(k(x + h)) - \sin(kx)\|_\infty = \|\sin(x + 1) - \sin(x)\|_\infty \) is not. 

3.4 Relation of Classical and Nonstandard Constructions

Assume \( V(\star X) \) is the bounded ultrapower of an ultrafilter \( \mathcal{U} \) over \( I \). Then the isomorphism \( \iota \) of theorem 3.3 allows us to identify \( i\mathcal{U}(E)/c_\mathcal{U} \) and \( \hat{E} \). We can also consider \( m^T/c_\mathcal{U} \cap m^T \) to be a subspace of \( l^\infty(E)/c_\mathcal{U} \) (via the injective isometry \( \phi \) of lemma 3.6).

**Lemma 3.10.** \( \hat{E}_{\text{max}} \) is the maximal continuous subspace of \( l^\infty(E)/c_\mathcal{U} \) with respect to \( \hat{T} \)

(More formally, one would have to write \( \hat{E}_{\text{max}} = \iota((l^\infty(E)/c_\mathcal{U})^{(\hat{T} - \text{max})}) \).

**Proof.** This follows from lemma 3.8, and the fact that \( \iota(\hat{T}(t)f) = \hat{T}(t)(\iota(f)) \) for all \( f \in l^\infty(E)/c_\mathcal{U} \).

**Lemma 3.11.** \( m^T/c_\mathcal{U} \cap m^T \subset \hat{E}_T \)

(Again, more formally this should be written as \( \iota(\phi(m^T/c_\mathcal{U} \cap m^T)) \subset \hat{E}_T \).

**Proof.** By definition, \( \langle f_i \rangle \in m^T \) iff for all reals \( \epsilon > 0 \) there is a real \( \delta > 0 \) such that \( \|T(t)f_i - f_i\|_\infty < \epsilon \) for all reals \( t < \delta \). Let \( f \in E \) denote \( t < f_i \). Assume that \( h \) is an infinitesimal nonstandard real. We want to show that for an arbitrary fixed positive real \( \epsilon \), \( |T(h)f - f| < \epsilon \). Let \( \delta \) be the real corresponding to \( \epsilon \) as above, \( h \) corresponds to a sequence of reals \( \{h_i\} \) (\( i \in I \)) such that \( U = \{i \in I : h_i < \delta \} \) is in the ultrafilter. \( *T(h)f - f \) corresponds to the sequence \( *T(h_i)f_i - f_i \). If \( i \) is in \( U \), then \( |T(h_i)f_i - f_i| < \epsilon, \) and \( U \) is a filter–set, therefore \( |T(h_i)f - f| < \epsilon \).

It is not immediately clear whether \( m^T/c_\mathcal{U} \cap m^T \) is always identical to \( \hat{E}_T \).

One could construct a counterexample under the following assumption:

**Assumption 3.12.** Fix \( \omega, M, \eta, \varepsilon_1, \varepsilon_2, \ldots, \delta_1, \delta_2, \ldots \). Assume that for all \( n, m \in \mathbb{N}^+ \) there is a Banachspace \( E^n_m \), a continuous semigroup \( T^n_m \) with \( T^n_m(t) < Me^{\omega t} \) and a \( f^n_m \in E^n_m \) such that

1. \( |f^n_m| = 1 \)
2. \( |T^n_m(t)f^n_m - f^n_m| < \frac{1}{n} \) for all \( 1 \leq i \leq n, t < \delta_i \)
3. For all \( \bar{f} \in E^n_m \) such that \( |ar{f} - f^n_m| < \eta \) exists a \( t < \frac{1}{m} \) such that \( |T^n_m(t)\bar{f} - \bar{f}| > \varepsilon_n \)

8
If this assumption holds, then let the index set \( I \) be \( \mathbb{N}^+ \times \mathbb{N}^+ \), and define \( \bar{E} = f^\infty(E_i^1) \) with the sup–norm. (I.e. \( \langle f_{i,j} \rangle \in \bar{E} \) if \( f_{i,j} \in E_i^1 \) and \( |f_{i,j}| \) is bounded.) Then define e.g. apply a suitable filter–basis to [Lin88, theorem A.4]).

If this assumption holds, then let the index set \( I \) be \( \mathbb{N}^+ \times \mathbb{N}^+ \), and define \( h_n^m = (h_n^m(i,j)) \in E \) by

\[
h_n^m(i,j) = \begin{cases} f_n^m & \text{if } i = n, j = m, \\ 0 & \text{otherwise}. \end{cases}
\]

Assume that \( \mathcal{U} \) is an ultrafilter over \( I = \mathbb{N}^+ \times \mathbb{N}^+ \), and that there is a partition \( \{\sigma_{i,j}\} \) \((i,j) \in \mathbb{N}\) of \( I \) such that for all \( n \in \mathbb{N} \) and all functions \( f : \mathbb{N} \to \mathbb{N} \), \( \bigcup_{i>n, j>f(i)} \sigma_{i,j} \in \mathcal{U} \) (it is easy to see that such a countably incomplete filter exists, e.g. apply a suitable filter–basis to [Lin88, theorem A.4]).

Then define \( k = \langle k_{i,j} \rangle \in \bar{E} \) by \( k_{i,j} = h_n^m \), where \( n, m \) is the (unique) pair of natural numbers such that \( (i,j) \) is an element of \( \sigma_{n,m} \).

Now consider the nonstandard extension defined by \( \mathcal{U} \), and interpret \( k \) as nonstandard element of \( *E \).

Clearly \( |k| = 1 \), since \( |k_{i,j}| = 1 \) for all \( (i,j) \). For all natural numbers \( n, 0 < t < \varepsilon_n \) and \( (i,j) \in \bigcup_{r>n, s \in \omega} \sigma_{r,s} \): \( |T(t)k_{i,j} - k_{i,j}| < \frac{1}{m} \). So if \( \langle r_{i,j} \rangle \) is infinitesimal, then so is \( |T(r)k - k| \), i.e. \( k \in E_T \).

Assume that the equivalence class of \( k \) is in \( m^T/e_{\mathcal{U}} \cap m^T \). Pick a representant \( \langle k_{i,j} \rangle \in m^T \), and \( U \in \mathcal{U} \) such that \( |k_{i,j} - k_{i,j}| < \eta \) for all \( (i,j) \in U \). Since \( U \in \mathcal{U} \), there is an \( n_0 \) such that for all \( m \) there is an \( m' \) such that \( \sigma_{n_0, m'} \cap U \neq \emptyset \). Since \( \langle k_{i} \rangle \in m^T \), there is a \( m_0 \in \mathbb{N} \) such that \( |T(t)k_i - k_i| < \delta_{n_0} \) for all \( (i,j) \in I \) and \( 0 < t < \frac{1}{m_0} \). If \( m_0' > m_0 \) and \( (i_0, j_0) \in \sigma_{n_0, m_0'} \cap U \), then there is a \( t \in \mathbb{R}^+ \) such that \( t < \frac{1}{m_0'} < \frac{1}{m_0} \) and \( |T(t)k_i - k_i| \geq \delta_{n_0} \), a contradiction.

However, our investigation of the nonstandard generator of a semigroup will show that \( m^T/e_{\mathcal{U}} \cap m^T = \bar{E}_T \). 

\[
|T(t)h - h| \quad \text{for different } h \text{'s}
\]
4 The Generator

4.1 The Generator in $^\ast E$

If $T$ is a continuous semigroup, then $^\ast T(t)$ maps the finite (or infinitesimal) elements of $^\ast E$ to finite (or infinitesimal, resp.) elements for all finite $t \geq 0$. That is not true for the (unbounded) linear map $A$, as the following trivial example shows:

**Example 4.1.** Let $T$ be the translation semigroup on $C^b$ (as in example 2.2), $V(^\ast X)$ a nonstandard extension, $k$ an infinite natural number. Then there is an infinitesimal $f_1 \in ^\ast E$ such that $f_1 \in ^\ast D(A)$ and $^\ast A(f)$ is infinite.

**Proof.** Define $f_1$ by case distinction:

$$f_1 = \begin{cases} 
0 & x < 0 \\
k^3x^2 & 0 \leq x < \frac{1}{k^2} \\
-k^3x^2 + 4kx - \frac{2}{k} & \frac{1}{k^2} \leq x < \frac{2}{k^2} \\
\frac{2}{k} & \frac{2}{k^2} \leq x 
\end{cases}$$

Then $^\ast Af_1 = \begin{cases} 
0 & x < 0 \\
2k^3x & 0 \leq x < \frac{1}{k^2} \\
-2k^3x + 4k & \frac{1}{k^2} \leq x < \frac{2}{k^2} \\
0 & \frac{2}{k^2} \leq x 
\end{cases}$ 

Let $V(^\ast X)$ be a nonstandard universe. Then the subspace $D(A)$ of $E$ is mapped to a subspace $^\ast D(A)$ of $^\ast E$.

**Lemma 4.2.** Assume, $f$ and $g$ are elements of $^\ast D(A)$

1. If $f$ and $^\ast A(f)$ are both finite, then $f \in E_T$.
2. If $f$ is finite and $^\ast A(f) \in E_T$, then $^\ast \frac{T(h)f-f}{h} \approx \ast A(f)$ for all positive infinitesimal reals $h$.
3. If $k \in ^\ast E$ and $^\ast \frac{T(h)f-f}{h} \approx k$ for all positive infinitesimal reals $h$, then $k \approx ^\ast A(f)$
4. If $f, g, ^\ast A(f)$ and $^\ast A(g)$ all are in $E_T$, and $f \approx g$, then $^\ast A(f) \approx ^\ast A(g)$
Proof. 1. By transfer of \( \text{Pr.1} \) we get: \(|T(t)f - f| \leq t \cdot \sup_{s \leq t} \|T(s)\| \cdot |A(f)| \leq tM(e^{\eta t} + 1) |A(f)| \), which is infinitesimal for infinitesimal \( t \).

2. For every standard \( \varepsilon > 0 \) and infinitesimal \( s \), we have \(|T(s)^* A(f) - A(f)| \leq \varepsilon \). Therefore transfer of \( \text{Pr.1} \) implies that \( \frac{|T(h)f - f|}{h} - A(f) \) is infinitesimal for infinitesimal \( h \). Since \( \varepsilon \) was arbitrary, \( \frac{|T(h)f - f|}{h} - A(f) \) is infinitesimal.

3. By transfer of the definitions of \( A \) and \( D(A) \), we get the following: For all positive nonstandard reals \( \varepsilon \) there is a positive nonstandard real \( \delta \) such that \( \frac{|T(h)f - f|}{h} - A(f) \) is infinitesimal for infinitesimal \( h \). Let \( \varepsilon \) be a fixed positive infinitesimal, and choose an infinitesimal \( h \leq \delta \) for the appropriate \( \delta \). Then \( \frac{|T(h)f - f|}{h} \approx A(f) \), and by assumption \( \frac{|T(h)f - f|}{h} \approx A(f) \), therefore \( k \approx A(f) \).

4. Since \( A(f) \in E_T \), \( \frac{|T(h)f - f|}{h} \approx A(f) \) for all infinitesimal \( h \), and the same applies to \( g \) and \( A(g) \). So we have \(|A(f) - A(g)| \leq |A(f) - \frac{|T(h)f - f|}{h}| + |\frac{|T(h)f - f|}{h} - \frac{|T(h)g - g|}{h}| + |\frac{|T(h)g - g|}{h} - A(g)| \leq \varepsilon \). So we just have to show that \( \frac{|T(h)f - f|}{h} - \frac{|T(h)g - g|}{h} \approx A(f) \) is infinitesimal for infinitesimal \( h \). Transfer of \( \text{Pr.1} \) shows that \( \frac{|T(h)(f - g)|}{h} \leq \sup_{|s| < h} \|T(s)\| \cdot |A(k)| \) for all positive \( h \) and \( k \in A(D(A)) \). Now apply this to \( k = f - g \).

As we have already seen in example \( \text{Ex.1} \), \( f \approx g \) does not imply \( A(f) \approx A(g) \) (set \( f := f_1, g := 0 \)). Also, it is not enough to assume that \( f, g \), \( A(f) \) and \( A(g) \) are all in \( E_{\text{max}} \cap D(A) \) for the implication to hold:

**Example 4.3.** Assume \( T, k \) and \( f \) are as in example \( \text{Ex.0} \). Define \( g(x) := -\cos \frac{kx}{k} \). Then \( g \approx 0 \). Clearly \( g \in E_{\text{max}} \) (it is even in \( E_T \)), and \( A(g) = f \), i.e. \( A(g) \in E_{\text{max}} \), but \( A(g) \) is not infinitesimal.

The same example shows that \( g \in E_T \) does not imply \( A(g) \in E_T \).

### 4.2 The Generator in \( \hat{E}_T \)

As we have already seen in lemma \( \text{Lm.8} \), \( \hat{T} \) is a continuous semigroup on \( \hat{E}_T \) (since \( E_T \) is a subspace of \( E_{\text{max}} \)). The generator is called \( \hat{A} \).

**Theorem 4.4.** \( \hat{f} \) is element of \( D(\hat{A}) \), iff there is a representant \( f \) of \( \hat{f} \) such that \( f \) is in \( D^*A \) and \( A(f) \) is in \( E_T \). In this case, \( \hat{A}(\hat{f}) = \hat{A}(f) \).

**Proof.** Assume \( \hat{f} \) has a representant \( f \) as in the lemma. We have to show that \( \hat{f} \in D(\hat{A}) \) and \( \hat{A}(\hat{f}) = \hat{A}(f) \), i.e. we fix a (standard) real \( \varepsilon > 0 \) and have to find a \( \delta > 0 \) such that \( \frac{|\hat{T}(h)f - f|}{h} - \hat{A}(f) \) is infinitesimal for infinitesimal \( h \). Note that \( n \) is an internal function, since it is element of \( \{ h \mapsto |\frac{1}{T(h)f - f} - A(f) : f \in D(A) \} \). Therefore the set \( X = \{ h : n(h) \geq \varepsilon \} \) is internal as well, and we can apply the spillover principle \( \text{Pr.1} \). Assume toward a contradiction that for all standard \( \delta > 0 \) there was a standard \( h < \delta \) such that \( n(h) \geq \varepsilon \), i.e. there are arbitrary small standard reals in \( X \). Then there is a infinitesimal real in \( X \) as well, a contradiction. Therefore \( \hat{f} \in D(\hat{A}) \).

Assume on the other hand that \( \hat{f}, \hat{g} \) are elements of \( \hat{E}_T \) such that \( \hat{A}(\hat{f}) = \hat{g} \). We want to show that \( f \in D^*A \) and \( A(f) \in E_T \) for some representant \( f \) of \( \hat{f} \). Let \( f, g \)
be arbitrary representants of \( f \) and \( g \), resp. (According to example\( \ref{ex:nonstandard-naturals} \), we cannot hope that \( \hat{f} \) already has the required properties.) For all nonstandard natural numbers \( m \) define \( c_m \) to be the set if nonstandard natural numbers \( n > m \) such that \( |\frac{\phi(T(h)g - f)}{h} - g'| < \frac{1}{m} \). For all standard natural numbers \( m \), the set \( c_m \) is not empty, since \( \hat{A}(f) = \hat{g} \). The set \( X = \{ m : c_M \neq \emptyset \} \) is internal, and contains all standard natural number, therefore it contains an infinite natural number as well (according to the spillover principle). Let \( m \) be such an infinite number, and \( n \) an element of \( c_m \). Now we apply the transfer of \( \ref{ex:transfer} \), setting \( h := \frac{1}{n} \). So we get a \( f \) in \( D^{\ast}(A) \) such that \( |\hat{f} - f| \leq \sup_{s \leq h}(|T(s(f - f)|) \), which is infinitesimal, since \( \hat{f} \in E_T \) and \( s \) is infinitesimal. Therefore \( f \) is a representant of \( \hat{f} \) as well. Also, \( *A(f) = \frac{T(h)\hat{f} - f}{h} \), so \( |*A(f) - *A(\hat{g})| \leq \frac{1}{m} \) is infinitesimal, therefore \( *A(f) \in E_T \) as well.

\[ \square \]

Let \( V(\ast X) \) be a bounded ultrafilter, \( T \) continuous with generator \( A \).

### 4.3 The equivalence of \( F \)-product and nonstandard hull

**Lemma 4.5.** \( \hat{E}_T = m^T/cu \cap m^T \)

**Proof.** Assume \( m^T/cu \cap m^T \subset \hat{E}_T \). Since \( m^T/cu \cap m^T \) is a closed subspace of \( \hat{E}_T \) and \( D(\hat{A}) \) dense in \( \hat{E}_T \), there must be a \( \hat{f} \) which is element of \( D(\hat{A}) \) but not \( m^T/cu \cap m^T \). We chose a representant \( f \) of \( \hat{f} \) such that \( f \in D(\ast(A)) \), \( \ast A f \in E_T \). Since \( f \) is an element of the ultraproduct, \( f \) is an equivalence class of a sequence \( f_i \) \((i \in I)\) such that for all \( i \) \( f_i \) \((D(A), \langle A(f_i) \rangle \in l^{\infty}(E) \). But then \( |\hat{T}(h)\hat{f} - f| = \sup_{s \in I}|T(h)f_i - f_i| | \leq \sup_{s \in I}(|A(f_i)| \cdot \sup_{s \leq h}(||T(s)||)) \) (according to \( \ref{ex:transfer} \)), so \( f \in m^T \), a contradiction.

Combining this with \( \ref{ex:nonstandard-naturals} \) and \( \ref{ex:transfer} \), using the isometry \( \iota \) of lemma \( \ref{ex:transfer} \) we get:

**Theorem 4.6.** \( \hat{E} \) is isomorphic to \( l^{\infty}(E)/cu \), and \( \hat{E}_T \) is isomorphic to \( m^T/cu \cap m^T \).

So we get the following picture (\( p \) are the canonical projections from a space to its quotient, and \( \gamma \) maps a finite element \( f \) of \( \ast E \) to the equivalence class \( \hat{f} \). The maps labeled with \( p \) and \( \gamma \) are surjective, the ones labeled with \( \cong \) are isometries. \( > \) denotes the subspace–relation, for \( > \) the isometry \( \phi \) of lemma \( \ref{ex:transfer} \) is used):

\[
\begin{array}{cccc}
\lim_{\infty}(E) & > & m^T & > \\
p & & p & \\
\begin{array}{ccc}
l^{\infty}(E)/cu & > & (l^{\infty}(E)/cu)^{T\text{-max}} & > 1 \setminus m^T/cu \cap m^T \\
\cong & & \cong & \\
\hat{E} & > & \hat{E}_{\text{max}} & > \hat{E}_T \\
\sim & & \sim & \\
\lim \ast E & > & \lim \ast E_{\text{max}} & > \lim \ast E_T
\end{array}
\end{array}
\]

(Remark: The entries of the first three rows are Banachspaces, the last row consists of vectorspaces.)

So we know that assumption \( \ref{assumption:nonstandard-naturals} \) cannot hold. This proves

12
Corollary 4.7. Assume that $T^n_m$ are contraction semigroups on $E$ (i.e. for all $t \in \mathbb{R}^+, \|T(t)\| \leq 1$), and and $f^n_m \in E$ are such that $|f^n_m| = 1$ and $|T^n_m(t)f^n_m - f^n_m| < \frac{1}{n}$ for all $t < \frac{1}{n}$. Then there is a $f' \in E$, and $n, m$, s.t. $|f' - f^n_m| < \frac{1}{2}$ and $|T^n_m(t)f' - f'| < \frac{1}{n}$ for all $t < \frac{1}{n}$.
