Front. Cell Dev. Biol. 8:611354. doi: 10.3389/fcell.2020.611354

INTRODUCTION

Metabolic syndrome, including obesity and diabetes as well as their vascular complications such as atherosclerosis, are chronic inflammatory diseases (Ross, 1999; Libby, 2002; Weisberg et al., 2003; Xu et al., 2003; Lumeng and Saltiel, 2011). These diseases are initiated by recruitment of circulating leukocytes, including monocytes, T cells, neutrophils, and NK cells, to the metabolic organs/tissues...
and vascular walls (Ley et al., 2007; Shi and Pamer, 2011). The infiltrated leukocytes survive in the affected organs/tissues, modulate their activation status and subsequently conquer the progression of these metabolic disorders and their complications. The importance of leukocyte recruitment and activation in the development and progression of these diseases has been demonstrated in various studies in which disease development is suppressed by genetic or pharmacologic blockade of leukocyte recruitment molecules such as selectins, selectin ligands, integrins, ligands for integrins, chemokines and chemokine receptors (Ley et al., 2007; Wu and Ballantyne, 2020). Furthermore, reduction of survival and activation of these infiltrated leukocytes are also able to inhibit these metabolic disorders and their complications (Murray and Wynn, 2011).

The role of cellular metabolism in redirecting the fate of leukocytes and their activities has attracted interest in the field. A large number of studies focused on the metabolic status of leukocytes and its dynamic changes during homeostasis and inflammation and highlighted that the metabolic status of leukocytes can undergo reprogramming in response to environmental stimuli (Webb et al., 2017; Marelli-Berg and Jangani, 2018). Aerobic glycolysis appears to be the most important metabolic pathway in leukocytes to produce ATP rapidly and sufficiently to support leukocyte recruitment and migration. It has been reported that macrophage HIF1α deficiency significantly suppressed migration under hypoxic conditions, and the results suggest that glycolysis sustains macrophage migration into inflamed tissues (Semba et al., 2016). In addition to macrophage migration, it has been demonstrated that macrophages largely depend on glucose supply through glycolysis-induced ATP production in cell spreading and protrusion formation (Venter et al., 2014). However, less is known about the impact of metabolic alterations on leukocyte recruitment and survival in diet-induced metabolic syndrome.

AMPK/PRKA acts as a major cellular energy sensor and a master regulator of metabolic homeostasis, including regulating the signals involved in glucose, lipid and cholesterol metabolism (Hardie and Hawley, 2001; Hardie, 2004). In mammals, AMPK/PRKA exists as a conserved serine/threonine kinase comprised of a catalytic subunit (α) and two regulatory subunits (β and γ). AMPKα1/PRKAA1 is the predominant isoform found in vascular cells and monocytes/macrophages, while AMPKα2/PRKAA2 is the catalytic isoform expressed in the liver, muscle and hypothalamus (Kahn et al., 2005; Fisslthaler and Fleming, 2009; Hardie, 2011). A few groups have extensively studied the role of AMPKα1/PRKAA1 in regulating cardiovascular functions and the development of cardiovascular diseases (Cai et al., 2016; Ding et al., 2017; Wu and Zou, 2020). In most of these studies, the kinase function of AMPKα1/PRKAA1 has been emphasized. AMPKα1/PRKAA1 is a well-characterized molecule for modulating cellular metabolism, including metabolism of glucose and fatty acid oxidation, in metabolic tissue/organs (Garcia and Shaw, 2017; Boudaba et al., 2018; Wu et al., 2018). For cardiovascular cells, we recently examined the role of AMPKα1/PRKAA1/Prkaa1 in glucose metabolism of cultured human endothelial cells and mouse endothelial cells in vivo (Yang et al., 2018); the role of AMPKα1/PRKAA1/Prkaa1 in macrophage metabolism, such as glucose metabolism, has not been studied. Here, we examined glycolysis in Prkaa1-deficient myeloid cells and the effects of this changed metabolism to myeloid cell recruitment and survival, as well as to the development of chronic inflammatory diseases, including diet-induced diabetes and atherosclerosis.

MATERIALS AND METHODS

Mouse Generation and Breeding

Prkaa1-floxed (Prkaa1lox/lox, Prkaa1WT) mice were kindly provided by Dr. Benoit Viollet (Institut Cochin, Paris, France). These mice were first crossed with myeloid-specific Cre recombinase-expressing mice (Ly5.1Cre/Cre, LysmCre/Cre, Prkaa1ATm mice, and then these mice were further bred with apolipoprotein E-deficient mice (Apoetm mice, Cat. No. 002052, the Jackson Laboratory, Bar Harbor, ME, United States) to generate Prkaa1lox/lox; LysmCre/+; Prkaa1ATm mice, and Apoetm; Prkaa1ATm mice. All mice were bred on the C57BL/6J background. In this study, both male and female deficient mice and their littermate controls were used for experiments. Mice were generally maintained on a 12:12-h of light: dark cycle in temperature-controlled cages and had free access to water and diet. All animal experiments were performed in accordance with the National Institutes of Health guidelines and approved by the IACUC (Institutional Animal Care & Use Committee) of Augusta University.

Glucose and Insulin Tolerance Tests

Six-week-old Prkaa1ATm and Prkaa1WT mice were fed a high-fat diet (HFD) (Cat. No. D12492, Research Diet, New Brunswick, NJ, United States) for 12 weeks. For glucose tolerance test (GTT), mice fed with HFD for 10 weeks were fasted for 6 h and administered D-glucose (1 g/kg; Cat. No. G8270, Sigma-Aldrich, St. Louis, MO, United States) by intraperitoneal (IP) injection. Insulin tolerance was assessed after 4 h fast by IP injection of insulin (1 U/kg; Cat. No. H10219, Lilly, Indianapolis, IN, United States). Blood samples were collected from the tail vein and the blood glucose was measured with a glucometer (OneTouch UltraEasy, Johnson & Johnson, New Brunswick, NJ, United States) at the indicated time after injection.

Evaluation of Energy Homeostasis

The volume of carbon dioxide production (VCO2), volume of oxygen consumption (VO2), energy expenditure, and food and drink intake were monitored individually in Prkaa1ATm and Prkaa1WT mice fed the HFD for 12 weeks with Comprehensive Lab Animal Monitoring System (CLAMS) (Columbus Instruments, Columbus, OH, United States). The ratio of VCO2 to VO2 was calculated for the respiratory exchange ratio (RER). Body composition of fat and lean mass was determined by a nuclear magnetic resonance (NMR) system (MiniSpec LF90II TD-NMR Analyzer, Bruker, Billerica, MA, United States).
Leukocyte Sorting From Adipose Tissue

Epididymal adipose tissue was excised from Prkaa1ΔMφ and Prkaa1WT mice and minced into small pieces, digested with collagenase type I (5 mg/ml; Cat. No. 4194, Worthington, Lakewood, NJ, United States) in DMEM (Cat. No. 11054020, Gibco, Waltham, MA, United States) for 30 min at 37°C with shaking. After centrifugation at 500 g for 5 min, the stromal vascular fraction (SVF) was resuspended in FACS buffer (0.5% FBS in PBS) and passed through a 70-µm cell strainer. The cells were incubated with FcR blocking reagent (Cat. No. 553142, BD Biosciences, San Jose, CA, United States) for 10 min at 4°C, then incubated with 7-AAD (Cat. No. 559925, BD Biosciences, San Jose, CA, United States), PE anti-mouse CD31 (4 µg/ml; Cat. No. 553373, BD Biosciences, San Jose, CA, United States) and APC anti-mouse CD45 (3 µg/ml; Cat. No. 558702, BD Biosciences, San Jose, CA, United States) for 30 min at 4°C. After washing, the cells were sorted using a FACS Caliber. The CD45+CD31−7-AAD− population was collected for RT-PCR analysis.

Atherosclerotic Lesion Analysis

Apoec−/−/Prkaa1ΔMφ and Apoec−/−/Prkaa1WT male and female mice at 7 weeks of age were fed a Western diet (Cat. No. TD88137, ENVIGO, Indianapolis, IN, United States) for 16 weeks. Mice were anesthetized and the blood samples were collected. After that, mouse hearts and aorta were dissected after perfusion with phosphate buffered saline (PBS) (Cat. No. 1450007, Thermo Fisher Scientific, Waltham, MA, United States) and 4% paraformaldehyde (PFA) (Cat. No. sc281692, Santa Cruz Biotechnology, Dallas, TX, United States), respectively. Tissues were then fixed with 4% PFA overnight. For the preparation of necrotic areas in atherosclerotic lesions, Masson trichrome staining was performed on 5-µm-thick sections of aortic sinus with Masson's Trichrome Stain Kit (Cat. No. KTMTR, American MasterTech, Lodi, CA, United States) according to the manufacturer's instruction. For Mac-2 immunohistochemistry staining on mouse adipose, sections of adipose were quenched with 3% hydrogen peroxide and blocked with 10% goat serum. Sections were then incubated with anti-Mac-2 (3 µg/ml, Cat. No. ACL8942F, Accurate Chemical & Scientific, Westbury, NY, United States) at 4°C overnight. Biotinylated secondary antibodies were incubated and VECTASTAIN® ABC kit (Cat. No. PK-6100, Vector Labs, Burlingame, CA, United States) were applied according to the manufacturer's instructions. Necrotic area and collagen content and Mac-2 staining area were quantified with Image-Pro Plus software.

Immunofluorescence Analysis

Frozen sections were fixed with 4% PFA and permeabilized with PBS containing 0.5% Triton X-100. Paraffin sections were heated in citric acid buffer (10 mM, PH6.0) at 98°C for 10 min for antigen retrieval. Tissues were blocked with 10% normal goat serum (Cat. No. 50062Z, Thermo Fisher Scientific, Waltham, MA, United States) at room temperature for 1 h and incubated with primary antibodies, anti-Mac2 (Cat. No. ACL8942F, Accurate Chemical & Scientific, Westbury, NY, United States), anti-Prka1 (Cat. No. GTX112998, GeneTex, Irvine, CA, United States), anti-P-Prka (Cat. No. GTX523431, GeneTex, Irvine, CA, United States), anti-CD36 (Cat. No. Ab80080, Abcam, Cambridge, United Kingdom), anti-Pfkfb3 (Cat. No. 13763-1-AP, Proteintech, Rosemont, IL, United States), anti-Sic2a1 (Cat. No. Ab115730, Abcam, Cambridge, United Kingdom), anti-F4/80 (Cat. No. Ab6640, Abcam, Cambridge, United Kingdom), anti-CD68 (Cat. No. MA5-13324, Thermo Scientific, Waltham, MA, United States) at 4°C overnight. Sections were then incubated with AlexaFluor conjugated secondary antibodies (1:250, Invitrogen, Grand Island, NY, United States) or TUNEL mixture for 1 h according to the manufacturer's instructions. Sections were stained with DAPI (1 µg/mL, Thermo Fisher Scientific) for 5 min at room temperature and mounted. Images were obtained using an upright confocal microscope (Zeiss 780; Carl Zeiss).

Leukocyte Recruitment in the Mouse Cremaster Microcirculation

To perform the leukocyte recruitment analysis, the cremaster muscle model of TNF-α-induced inflammation was used. Each group included four Prkaa1ΔMφ and Prkaa1WT male mice at 8–12 weeks old. Briefly, mice were injected IP with 10 µg/kg recombinant murine TNF-α (Cat. No. 410-MT-010, R&D Systems, Minneapolis, MN, United States). 4 h later, mice were anesthetized with ketamine (125 mg/kg) and xylazine (12.5 mg/kg). Cremaster muscle was exteriorized from the scrotum and spread on the cover glass and superfused with warmed (35–37°C) saline to keep it wet. Movies were obtained with intravital microscopy (Axioskop; Carl Zeiss, Goettingen, Germany) with a digital camera (AxioCam MRm, Carl Zeiss) and analyzed using digital video software (ZEN 2012, Carl Zeiss). For each cremaster, 3–4 different postcapillary venules were examined and 3 different segments were recorded for
each venule. In total, 36–48 video clips were obtained and analyzed for each group. The number of cells rolling through a perpendicular line to the vessel axis per minute was measured as rolling flux. Leukocyte adhesion was defined as leukocyte adhesion to endothelium more than 30 s and measured as cell numbers per surface area. Surface area was calculated for each vessel as S = π*d^2*V where d is the diameter and V is the length of the vessel.

**Plasma Cholesterol, Triglyceride, Glucose, and Blood Leukocyte Analysis**

Blood was drawn from Apoe+/−/Prkaa1WT and Apo−/−/Prkaa1ΔMφ mice that were fasted for 12–14 h following 16 weeks of being fed a Western diet. The subsequent plasma samples were assayed enzymatically with the respective reagents (Cat. No. TR15421, TR13421, TR22421, Thermo Scientific) for measurement of glucose, cholesterol, and triglycerides. Leukocyte numbers in blood were counted with an automated blood cell counter (Hemavet 850FS, CDC Technologies, Oxford, CT, United States).

**Bone Marrow Derived Macrophage (BMDM) Culture and Treatments**

Prkaa1WT and Prkaa1ΔMφ mice at 8 weeks of age were euthanized. Femurs and tibias were isolated and transected. Bone marrow cells were obtained by flushing femurs and tibias with RPMI 1640 medium (Cat. No. SH30809.01B, HyClone, Logan, UT, United States). The cell suspension was pipetted repeatedly for measurement of glucose, cholesterol, and triglycerides. Leukocyte numbers in blood were counted with an automated blood cell counter (Hemavet 850FS, CDC Technologies, Oxford, CT, United States).

Wild-type (WT) and Prkaa1−/− BMDMs were differentiated into adherent macrophages, which were used to perform experiments. Cells were then assayed with XFe96 extracellular flux analyzer. The intracellular F-2, 6-P2 level was measured with the previously described method (Van Schaftingen et al., 1982). WT and Prkaa1−/− BMDMs were first seeded onto Seahorse XF24 culture cell plates at a concentration of 1.0 × 10^5 per well, and incubated with RPMI 1640 medium at 37°C overnight. The next day, the medium was replaced with substrate-limited medium (DMEM supplemented with 0.5 mM Glucose, 1 mM GlutaMAX, 0.5 mM carnitine and 1% FBS) for 24 h. Then cells were incubated with FAO assay medium (KHB supplemented with 2.5 mM glucose, 0.5 mM carnitine, and 5 mM HEPES, pH 7.0) for 45 min in a non-CO2 incubator at 37°C. XF Palmitate-BSA FAO Substrate or BSA (Cat. No. 102720-100, Agilent, Santa Clara, CA, United States) was added to the appropriate wells prior to starting the assay. Plates were then loaded onto an XF24 extracellular flux analyzer for XF Cell Mito Stress Test. Compounds were used in the test at the following concentrations: oligomycin (2 µM), FCCP (2 µM), rotenone (1 µM), and antimycin A (1 µM). Fatty acid oxidation was calculated by subtracting oxygen consumption rate (OCR) with palmitate-BSA by OCR with BSA. Spare respiratory capacity was calculated by subtracting baseline OCR from maximum OCR after FCCP injection.

**Lactate Measurement**

The lactate levels of WT and Prkaa1−/− BMDMs were determined with the Lactate Assay Kit (Cat. No. MAK064, Sigma, Louis, MO, United States) according to the manufacturer’s instructions. Briefly, cells were homogenized with lactate assay buffer and centrifuged at 13,000 g for 10 min. Samples were deproteinized with 10 kDa MWCO spin filter, and the soluble fraction was used directly to measure the intracellular lactate. The cell culture medium was used for measurement of the extracellular lactate level.

**F-2,6-P2 Level Assay**

The intracellular F-2, 6-P2 level was measured with the previously described method (Van Schaftingen et al., 1982). WT and Prkaa1−/− BMDMs were homogenized with 0.05M NaOH and inactivated at 80°C for 5 min. The samples were then centrifuged and neutralized with acetic acid. The mixture was centrifuged and the supernatants were collected for measurement. The levels of F-2,6-P2 were measured by a PPI-PFK-based kinetic reaction assay as shown in the table below (Table 1). The kinetic reaction was monitored at 340 nm for 30 min with Synergy H1 Hybrid

**Table 1**

| Substrate     | Initial concentration | Work concentration |
|---------------|-----------------------|--------------------|
| Tris-HCl (pH7.5) | 50 mM                 | 50 mM              |
| NADH          | 20 mM                 | 0.2 mM             |
| DTT           | 1 M                   | 5 mM               |
| F6P           | 200 mM                | 1 mM               |
| MgO2          | 1 M                   | 2 mM               |
| Aldolase      | 700 U/ml              | 0.7 U/ml           |
| GDH           | 450 U/ml              | 0.45 U/ml          |
| TIM           | 1200 U/ml             | 0.6 U/ml           |
| PPI-Na        | 25 mM                 | 0.5 mM             |
| PPI-PFK       | 10 µg/assay           |                    |

Frontiers in Cell and Developmental Biology | www.frontiersin.org  4 January 2021 | Volume 8 | Article 611354
FReader (BioTek, Winooski, VT, United States). The relative F2,6-P2 levels were normalized by protein concentration.

**Apoptosis Analysis**

Apoptosis analysis were performed with fluorescein isothiocyanate (FITC) Annexin V Apoptosis Detection Kit I (Cat. No. 556547, BD Biosciences) according to the manufacturer’s protocol. Briefly, WT and Prkaa1-deficient BMDMs were seeded into 6-well plates at a density of $2 \times 10^5$ cells/ml. After incubation for 24 h, cells were detached with 0.25% trypsin and incubated with 5 µl propidium iodide (PI) and 5 µl FITC Annexin V in 100 µl of 1 × binding buffer at room temperature for 15 min in the dark. The samples were analyzed by FACSCalibur flow cytometer (FACSCantor II, BD Biosciences) within 1 h. Apoptotic-positive cells were quantified with FlowJo.

For terminal transferase deoxytethyl uridine end labeling (TUNEL) staining, WT and Prkaa1-deficient BMDMs were seeded on glass coverslips at a density of $2 \times 10^5$ cells/ml. After incubation for 24 h, cells were stained with In Situ Cell Death Detection Kit (Cat. No. 12156792910, Roche) according to the manufacturer’s protocol. Briefly, cells were washed with PBS twice, fixed with 4% PFA for 15 min and permeabilized with PBS containing 0.5% Triton X-100 for 20 min at room temperature. Cells were then incubated with the TUNEL mixture containing TMR-dUTP and terminal deoxynucleotidyl transferase for 1 h at 37°C in the dark. Nuclei were stained with DAPI before mounting. Images were obtained using an upright confocal microscope (Zeiss 780, Carl Zeiss). The number of TUNEL-positive cells was counted in seven fields per slide.

**Chemotaxis Assays**

Chemotaxis assay of WT and Prkaa1-deficient BMDMs was performed in a transwell chamber equipped with a 6.5-mm-diameter polycarbonate filter with 8-µm pore inserts (Cat. No. 353097, Corning, NY, United States). Briefly, RPMI 1640 medium containing 0.5% FBS with or without MCP-1 (50 ng/ml, Cat. No.479-JE, R&D Systems Inc., Minneapolis, MN, United States) was placed in the lower wells. $2 \times 10^5$ BMDMs suspended in RPMI 1640 containing 0.5% FBS were placed in the inserts. The chambers were incubated at 37°C for 8 h. Non-migrated cells on the upper side of inserts were removed with a cotton tip, and migrated cells on the lower side were fixed and stained with crystal violet. BMDMs in 5–7 random fields were counted for each transwell.

**Western-Blot Analysis**

Wild-type and Prkaa1-deficient BMDMs were lysed with RIPA lysis buffer (Sigma) supplemented with 1% phosphatase inhibitors and 1% protease (Roche) for 10 min on ice. After centrifugation of cell lysates at 4°C for 5 min, samples were assayed for protein concentrations by the BCA assay and then separated with SDS-PAGE gel with 10–20 µg protein per lane. Western-blot analysis was performed with primary antibodies against Prkaa1 (1:1000, Cat. No. ab110036, Abcam), Slc2a1 (1:5000, Cat. No. ab115730, Abcam), Pfkfb3 (1:1000, Cat. No. ab181681, Abcam), and β-actin (1:2000, Cat. No. sc47778, Santa Cruz Biotechnology). Images were obtained with the CheminDoc MP System (Bio-Rad) and quantified with Image J software. All protein levels were normalized with β-actin level.

**Real-Time PCR Analysis**

Total RNA of WT and Prkaa1-deficient BMDMs were extracted using Trizol Reagent (Cat. No. 15596018, Invitrogen, Grand Island, NY, United States). 0.5–1 μg total RNA was used for reverse transcription reaction with iScript cDNA synthesis kit (Cat. No. 170-8891, Bio Rad, Hercules, CA, United States). Real-Time PCR was performed in a StepOne Plus system (Applied Biosystems) with Power SYBR Green PCR Master Mix (Cat. No. 4367659, Life Technologies) according to the manufacturer’s protocol. Gene-specific primers used in this study are listed in Table 2. Relative gene expression was calculated with the efficiency-corrected $2^{-\Delta\Delta CT}$ method by using mouse Rplp0 RNA as the internal control.

**Statistical Analysis**

Statistical analysis was conducted with GraphPad Prism (La Jolla, CA, United States). The significance of the data was analyzed using unpaired Student’s t-test between two groups. Multiple comparisons were performed with one-way ANOVA analysis followed by Bonferroni’s post hoc tests. Statistical significance was defined as follows: *$p < 0.05$, **$p < 0.01$, ***$p < 0.001$. Data are represented as mean ± SEM. All biological experiments were repeated at least three times with independent cell cultures or individual animals (biological replications).

**RESULTS**

**Prkaa1 Expression Is Increased in Adipose Leukocytes of HFD-Fed Mice**

Obesity is a chronic, low-grade inflammation with progressive immune cell infiltration into adipose tissue (Bai and Sun, 2015). Many circulating leukocytes, especially monocytes, recruit to adipose tissue to enhance the inflammatory response, accelerating adipocyte necrosis and insulin resistance.

(Catalan et al., 2013). To explore Prka expression in infiltrating leukocytes in the context of metabolic diseases, we performed fluorescence-activated cell sorting (FACS) to isolate leukocytes from adipose tissues. Briefly, we digested adipose tissue with collagenase I to obtain SVFs, followed by incubation of SVFs with antibodies against CD31 (endothelial cell marker), CD45 (leukocyte marker) and 7-AAD (dead cell marker), and eventually harvested cells labeled as CD31^−^CD45^+^ 7-AAD^−^ from the cell suspension (Figure 1A and Supplementary Figure 1). Next, the sorted leukocytes were subjected to Real-time PCR analysis for the mRNA expression of *Prkaa1* and *Prkaa2*. The results showed that the mRNA levels of *Prkaa1* and *Prkaa2* were much higher in leukocytes from adipose tissues of mice fed HFD for 8 weeks than mice fed chow diet (CD) (Figure 1B). Prkaa1 is the major isoform of Prkaa in leukocytes (Zhang et al., 2017), and our recent study shows
a critical role of Prkaa1 in metabolic regulation in vascular cells (Yang et al., 2018). We analyzed expression of metabolic genes in sorted cells with qPCR. The mRNA levels of Slc2a1, a glucose transporter, and 6-phosphofructo-2-kinase/fructose-2,6-bisphosphatase isoenzyme 3 (Pfkfb3), a critical glycolytic regulatory enzyme (activator), were much higher in adipose leukocytes of HFD-fed mice than those of CD-fed mice (Figure 1C). Additionally, the mRNA levels of Cd36, a transporter for free fatty acids and Cpt1, a mitochondrial enzyme important for fatty acid oxygenation, were also increased in adipose leukocytes of HFD-fed mice compared with those of chow diet-fed mice (Figure 1D). Since macrophages are the predominate leukocytes infiltrating in adipose, we examined the expression of Prkaa1 and some of the above metabolic molecules in F4/80-positive cells by immunostaining adipose sections with the relevant antibodies. The levels of Prkaa1, pPrkaa1, Slc2a1, Pfkfb3 and CD36 were much higher in HFD-fed mice than CD-fed mice (Figures 1E,F and Supplementary Figure 2). Taken together, the data suggest that leukocytes infiltrated into adipose tissue, especially monocytes/macrophages, exhibit increased levels of Prkaa1, and the latter is associated with increased expression of molecules important for glucose and lipid metabolism.

**Prkaa1 Regulates Macrophage Glycolysis**

Since macrophages are the major population of infiltrated leukocytes in adipose, we used cultured BMDMs to examine the causal effect of Prkaa1 on macrophage metabolism. BMDMs were cultured with bone marrow cells from Prkaa1WT and Prkaa1ΔMϕ mice (Supplementary Figures 3A,B). BMDMs cultured with bone marrow cells of Prkaa1ΔMϕ mice barely expressed Prkaa1 at the protein level compared to BMDMs of control Prkaa1WT mice (Supplementary Figure 3C), indicating that Prkaa1 was successfully knocked out in myeloid cells. With qPCR, the major genes important for glycolysis were examined, and the mRNA levels of glycolytic genes, including Pfkfb3, Hk1, Pkm2, Ldha, Eno1, and Gpi, were significantly reduced in Prkaa1-deficient BMDMs compared with those of Prkaa1 WT BMDMs (Figure 2A). Expression of Slc2a1 and Pfkfb3 were examined with Western blotting. The protein
**FIGURE 4** Myeloid Prkaa1 deficiency protects mice from HFD-induced insulin resistance. (A) Body weight of Prkaa1WT and Prkaa1ΔMΦ male mice during 12 weeks of HFD feeding. n = 9. (B) Fat and lean content of Prkaa1WT and Prkaa1ΔMΦ male mice after being fed HFD for 12 weeks. n = 9. (C) Fasting blood glucose levels of Prkaa1WT and Prkaa1ΔMΦ male mice after being fed HFD for 12 weeks. n = 8. (D) Blood glucose levels (left) and AUC (area under the curve, right) during GTT (glucose tolerance test) in Prkaa1WT and Prkaa1ΔMΦ male mice after being fed HFD for 10 weeks. n = 6. Mice were fasted for 16 h and injected with glucose (2 g/kg IP). (E) Blood glucose levels (left) and AUC (right) during ITT (insulin tolerance test) in Prkaa1WT and Prkaa1ΔMΦ male mice after being fed HFD for 11 weeks. n = 6.
levels of these molecules were much lower in Prkaa1-deficient BMDMs than WT BMDMs (Figure 2B). Posttranscriptional regulation of Slc2a1 by Prkaa1 at the protein, but not mRNA, level was observed in Prkaa1-deficient BMDMs. Consistent with the decreased expression of Pfkfb3, the level of fructose-2,6-bisphosphate [(the product of Pfkfb3, and the most potent allosteric activator of 6-phosphofructo-1-kinase (PFK1)] was also decreased in Prkaa1-deficient BMDMs (Figure 2C). The level of lactate, the end product of glycolysis, was also reduced in Prkaa1-deficient BMDMs compared with that in control cells (Figure 2C). Importantly, we assessed glycolytic metabolism in Prkaa1-deficient BMDMs using Seahorse Extracellular Flux analysis via measurement of the ECAR. As shown in Figure 2D, the glycolytic metabolism was increased in BMDMs stimulated with MCSF. In contrast, Prkaa1-deficient BMDMs exhibited significantly reduced basic glycolysis and glycolytic capacity compared with control cells either in the presence or absence of MCSF. Altogether, these results indicate that Prkaa1 is an endogenous regulator of glycolysis in macrophages.

We also evaluated fatty acid oxidation (FAO) in these BMDMs. The mRNA levels of FAO-associated genes, including Cd36, Fabp4, and Cpt1a, were significantly decreased in Prkaa1-deficient BMDMs compared with those in control BMDMs (Figure 2E). We next performed the Seahorse assay to determine the OCR in the presence of palmitate. As shown in Figure 2F, FAO was dramatically decreased in Prkaa1-deficient BMDMs compared with control cells. These results collectively suggest that Prkaa1 regulates FAO in macrophages.

Prkaa1 Deficiency Reduces Leukocyte Recruitment and Macrophage Viability

Glycolysis and FAO are important for leukocyte recruitment and survival. Therefore, we examined whether the decreased metabolism in PRKAA1/Prkaa1-deficient leukocytes affects leukocyte recruitment and viability. We first compared the migration capability of WT and Prkaa1-deficient BMDMs. In a transwell migration assay, WT macrophages exhibited robust migration to medium supplemented with MCP-1. This ability was markedly decreased for Prkaa1-deficient BMDMs (Figure 3A). To determine the functional consequences of Prkaa1 deficiency in leukocyte recruitment in vivo, Prkaa1<sup>WT</sup> and control Prkaa1<sup>ΔMϕ</sup> mice were injected with TNF-α (10 μg/ml) IP to induce vascular inflammation in vivo. Four hours after TNF-α treatment, leukocyte rolling and adhesion in the endothelium of postcapillary venules of mouse cremaster muscle were observed with intravital microscopy (Figure 3B). Mild trauma caused by the exteriorization of the cremaster muscle led to fast leukocyte rolling. In Prkaa1<sup>ΔMϕ</sup> mice, the number of fast rolling leukocytes were comparable to that in Prkaa1<sup>WT</sup> mice (Figure 3C). TNF-α treatment stimulated the expression of adhesion molecules on the endothelium and induced slow rolling and adhesion of leukocytes in mice. The numbers of slow rolling and adhesion of leukocyte were reduced by 40–50% in Prkaa1<sup>ΔMϕ</sup> mice compared with those in control mice (Figure 3C). These results indicate compromised recruitment ability of Prkaa1-deficient leukocytes in mice. Taken together, these in vitro and in vivo findings support that Prkaa1-mediated metabolism is required for leukocyte recruitment and macrophage viability.

We also tested whether Prkaa1-mediated metabolism is important for viability of BMDMs. Flow cytometry analysis showed the percentage of Annexin V-positive BMDMs was much higher in Prkaa1-deficient BMDMs than WT cells (Figure 3D). Consistent results were obtained in BMDMs stained with TUNEL (Figure 3E). In mimicking the in vivo diabetic condition, we performed the above assays using BMDMs treated with high glucose (25 mM). The percentage of Annexin V-positive BMDMs was also increased for Prkaa1-deficient cells compared with that for WT cells (Supplementary Figure 4). These results reveal increased rates of apoptosis in the Prkaa1-deficient myeloid cells.

Myeloid Prkaa1 Deficiency Protects Mice From HFD-Induced Insulin Resistance

Leukocytes, including myeloid cells, participate in the development of HFD-induced metabolic syndrome (Weinstock et al., 2020). We examined whether Prkaa1 deficiency-mediated decreased leukocyte recruitment affects diet-induced metabolic syndrome. After being fed of HFD for 12 weeks, Prkaa1<sup>ΔMϕ</sup> mice displayed resistance to HFD-induced body-weight gain compared with that of Prkaa1<sup>WT</sup> mice (Figure 4A). Meanwhile, body composition analysis after feeding of HFD showed that Prkaa1<sup>ΔMϕ</sup> mice had a lower body fat content and correspondingly a higher percentage of lean mass than Prkaa1<sup>WT</sup> mice (Figure 4B). Of note, the fasting blood glucose level was significantly reduced in Prkaa1<sup>ΔMϕ</sup> mice compared with that in Prkaa1<sup>WT</sup> mice under the HFD condition (Figure 4C). Consistent with these results, Prkaa1<sup>ΔMϕ</sup> mice exhibited improved glucose clearance in GTTs, as well as improved insulin sensitivity in insulin tolerance tests (ITTs) compared with Prkaa1<sup>WT</sup> mice (Figures 4D,E). Furthermore, Mac2 staining on adipose sections showed a significant reduction in macrophage infiltration into adipose of Prkaa1<sup>ΔMϕ</sup> mice compared with that of Prkaa1<sup>WT</sup> mice (Figure 4F). Accordingly, lower levels of chemokines including Mcp-1 and Cxcl12 was also observed in adipose of Prkaa1<sup>ΔMϕ</sup> mice compared to Prkaa1<sup>WT</sup> mice under...

**FIGURE 5** Myeloid Prkaa1 deficiency increases energy expenditure in response to HFD. (A) Oxygen consumption (VO$_2$) of Prkaa$^{WT}$ and Prkaa$^{M}$ male mice during 12-h light and dark cycles recorded on the second day after acclimatization. (B) Carbon dioxide consumption (VCO$_2$) of Prkaa$^{WT}$ and Prkaa$^{M}$ male mice during 12-h light and dark cycles recorded on the second day after acclimatization. (C) Respiratory exchange ratio (RER) of Prkaa$^{WT}$ and Prkaa$^{M}$ male mice during 12-h light and dark cycles recorded on the second day after acclimatization. (D) Heat production of Prkaa$^{WT}$ and Prkaa$^{M}$ male mice during 12-h light and dark cycles. (E) Daily food and drink intake of Prkaa$^{WT}$ and Prkaa$^{M}$ male mice during light and dark cycles of animals fed HFD at room temperature (22°C). Area under the curve was calculated during light and dark cycles for each individual animal. RER is calculated by the ratio of VO$_2$ and VCO$_2$. Black horizontal bars denote the dark period of the day (12 h). AUC, area under the curve. All data are expressed as mean ± SEM. Statistical significance was determined by unpaired Student’s t-test. *p < 0.05 was considered significant, **p < 0.01, ***p < 0.001.
Myeloid Prkaa1 Deficiency Decreases Western-Diet Induced Atherosclerosis

We also examined whether Prkaa1 deficiency-mediated decreased leukocyte recruitment reduces diet-induced atherosclerosis. We bred Prkaa1ΔMϕ mice with Apoe−/− mice at both light and dark cycles (Figure 5D). In addition to higher energy expenditure, myeloid Prkaa1 deficiency also exhibited lower energy intake as indicated by lower daily food and drink intake. As shown in Figure 5E, Prkaa1ΔMϕ mice showed decreased daily food intake compared to Prkaa1WT mice. Although average daily drink has no significant difference between these two groups, the Prkaa1ΔMϕ mice still exhibited the trend of slightly lower drink intake than that of Prkaa1WT mice. As such, these results indicate that myeloid Prkaa1 increases energy expenditure and reduces energy intake in response to HFD-induced excessive nutrition.

mice and generated Apoec−/−/Prkaa1ΔMϕ atherosclerotic mice and their littermate Apoec−/−/Prkaa1WT mice. Starting from 7 weeks of age, these age- and gender-matched mice were fed a Western diet containing 42% calories from fat and 0.2% (wt/wt) cholesterol for 16 weeks. Apoec−/−/Prkaa1ΔMϕ mice showed significantly fewer and smaller lesions at the aortic arches both in male and female mice than littermate control mice (Figures 6A,C). This observation was confirmed with quantitative measurement of atherosclerotic lesions following Oil Red O (ORO) staining of aortas (Figures 6B,D). Decreased levels of cholesterol, triglyceride, and glucose in blood of both male and female Apoec−/−/Prkaa1ΔMϕ mice were found (Supplementary Figure 5), likely contributing to the alleviated atherosclerosis in Apoec−/−/Prkaa1ΔMϕ mice. Additionally, Apoec−/−/Prkaa1ΔMϕ mice exhibited no significant difference in the number of circulating white blood cells, including neutrophils, leukocytes and monocytes, compared with Apoec−/−/Prkaa1WT mice (Supplementary Figure 5).

Aortic sinuses from these mice were further examined to evaluate the effect of Prkaa1-deficient myeloid cells in determining the size and stability of atherosclerotic lesions. Immunostaining of aortic sinus sections with antibody of the macrophage marker Mac2 showed that the number of macrophages was much less in Apoec−/−/Prkaa1ΔMϕ mice than control mice (Figure 7A). Additionally, macrophage viability in aortic sinuses of these mice was analyzed by TUNEL staining. The number of TUNEL-positive cells was markedly increased in the aortic sinuses of Apoec−/−/Prkaa1ΔMϕ mice compared with those of control mice (Figure 7A). These observations indicate that the decreased number of macrophages in lesions of Apoec−/−/Prkaa1ΔMϕ mice is due to both decreased recruitment of monocytes to arterial vessels and increased apoptosis of macrophages in atherosclerotic lesions. As a result, the size of atherosclerotic lesions (Figure 7B), indicated with ORO staining, was decreased while the stability of atherosclerotic lesions, evident with necrotic cores with HE staining and collagen content by Masson’s trichrome staining (Figures 7C,D), was increased in Apoec−/−/Prkaa1ΔMϕ mice compared to those of control mice. Thus, mice with myeloid deletion of Prkaa1 exhibit less severe and more stable atherosclerosis.

DISCUSSION

In the present study, we found that Prkaa1 expression is upregulated in leukocytes sorted from adipose tissue of HFD-fed mice, and this was accompanied with upregulated genes associated with glycolysis and FAO. Accordingly, compromised glycolysis and FAO was observed in Prkaa1-deficient macrophages. Leukocyte recruitment, evidenced with macrophage migration in vitro and leukocyte rolling and adhesion in vivo, was compromised in the absence of Prkaa1. Consequently, chronic inflammatory disorders, including diet-induced diabetes and atherosclerosis, were reduced in Prkaa1ΔMϕ mice.

AMPKα1/PRKAA1 mediates glycolysis and FAO in macrophages. AMPK/PRKA serves as a master regulator of energy metabolism to control key factors involved in the many pathways to maintain energy balance. In addition to hypoxia, other stresses such as chronic inflammation and aberrant glucose and lipid levels enhance and/or activate AMPK/PRKA. Apoec deficiency dysregulates the levels of glucose and lipids and causes chronic inflammation in mice. This may also result in increased function of AMPK. AMPK/PRKA maintains energy homeostasis by activating catabolic processes to increase ATP production and inhibiting anabolic processes to suppress ATP consumption. In order to replenish ATP stores, AMPK/PRKA actively stimulates glucose utilization by inducing glucose transporter expression and further increases glucose uptake into cells (Kim et al., 2010). AMPK/PRKA also has been reported to regulate glycolytic flux through the pathway by phosphorylating phosphofructo-2-kinase/fructose 2,6-bisphosphatase 3 (PFKFB3), which affects the activity of PFK1, a rate-limiting enzyme in glycolysis (Bando et al., 2005). Our previous study has demonstrated that AMPK/PRKA regulates glycolysis in part via the HIF1α pathway (Yang et al., 2018), and increased HIF1A expression promotes glycolysis, resulting in a rapid supply of ATP (Semenza, 2012). In addition to stimulating glycolysis, AMPK/PRKA also increases FAO by a reduction of the activity of ACC, decreased the level of malonyl-CoA, and resulted in increased fatty acid import into mitochondria for β-oxidation (Saggerson, 2008). The studies indicated that the AMPK–ACC–malonyl CoA–carnitine palmitoyl transferase 1 mechanism plays a key role in the physiological regulation of FAO (Dagher et al., 2001). Although these studies have indicated an interaction between AMPK/PRKA and cellular metabolism in cells of other types, our study has demonstrated that Prkaa1 is also critical in regulation of glycolysis and FAO in leukocytes in mice. Compromised production of ATP, especially on the actin compartment in Prkaa1-deficient leukocytes, may dramatically affect many steps of leukocyte recruitment, including rolling, adhesion and migration. Additionally, decreased energy production plus decreased metabolites of glycolysis and FAO may also result in compromised repair, leading to apoptosis of infiltrated macrophages.
The physiological effect of Prkaa1 in leukocytes revealed in this study may not explain the pharmacological effect of AMPK/PRKA activation. Over the past decades, much work has emerged to support the beneficial role of AMPK in chronic inflammatory disorders such as metabolic syndrome and inflammatory diseases (Cheang et al., 2014; Guma et al., 2015; Kjøbsted et al., 2015). It has been reported that metformin or AICAR attenuates Ang II-induced atheromatous plaque formation and protects against hyperglycemia-induced atherosclerosis (Li et al., 2010; Vasamsetti et al., 2015; Wang et al., 2017) and also reduces insulin resistance (Yang et al., 2012). These beneficial effects may operate mainly through the effect on cells other than myeloid cells, such as vascular cells or metabolic cells. Also, some beneficial effect from the use of metformin, AICAR or A769662 may be through an AMPK-independent pathway (Guigas et al., 2006; Kirchner et al., 2018). Additionally, pharmacological activation of AMPKα1 in leukocytes may also reduce inflammation through many other pathways than the metabolism induced by pharmacologically activated AMPKα1. All of these possibilities will be explored in our future studies.

Phenotypic variance is noted in myeloid Prkaa1-deficient mice. Mice that were deficient in myeloid Prkaa1, when bred to Ldr−/− mice, displayed enhanced macrophage inflammation, increased plasma cholesterol and triglyceride levels, and a phenotype of enhanced diet-induced obesity and insulin resistance as well as accelerated atherosclerosis (Cao et al., 2016). In contrast, Apoe−/− mice with Prkaa1 deletion or myeloid Prkaa1 deletion showed reduced monocyte differentiation and survival, thus attenuating the initiation and progression of atherosclerosis (Zhang et al., 2017). Apoe−/− mice with myeloid Prkaa2 deficiency developed smaller atherosclerotic plaques that contained fewer macrophages and less MMP9 than plaques from control mice through regulating myeloid DNA methylation (Fisslthaler et al., 2019). A very recent study did not find any difference in the size of atherosclerotic lesions between control Apoe−/− mice and Apoe−/− mice deficient in both Prkaa1 and Prkaa2 in myeloid cells (LeBlond et al., 2020). These inconsistent results from different studies indicate the disease phenotype is affected by many important experimental factors, such as background strain, littersmate control, diet and the stages of disease when mice were evaluated. In our study, we have followed a recently published protocol for rodent atherosclerosis (Daugherty et al., 2017). With our expertise in cell metabolism and leukocyte recruitment, we are confident of our conclusion in which AMPK/PRKAA1/Prkaa1-mediated metabolism is critical for myeloid cell recruitment and survival.

CONCLUSION

In conclusion, these findings clarify that AMPKα1 plays a key role in regulating macrophage glucose and lipid metabolism, further controls monocyte recruitment and macrophage viability, and eventually promotes the development of diet-induced insulin resistance and atherosclerosis. Targeting AMPKα1-driven macrophage metabolism could be a therapeutic intervention in cardiovascular diseases.

All data are expressed as mean ± SEM. Statistical significance was determined by unpaired Student’s t-test. *p < 0.05 was considered significant, **p < 0.01, ***p < 0.001.
