INTRODUCTION

Over 2.3 billion school-age children spend one-third of their time in schools. For many school-age children, schools are the first and the most accessible point of contact with health services. Health-promoting school focus on: caring for oneself and others, making healthy decisions and taking control over life’s circumstances. Thus creating conditions that are conducive to health, building capacities for preventing death, disease and disability caused by helminths, tobacco use, HIV/AIDS/STDs, sedentary lifestyle, drugs and alcohol, violence and injuries, unhealthy nutrition and health-related behaviours.

In 2016, leading causes of adolescent girls’ deaths were maternal conditions, self-harm and road injury, while other major causes include HIV/AIDS, road injury, lower respiratory infections, malaria and diarrhoeal diseases. A quarter of all deaths in male adolescents aged 15-19 years were due to road injury while HIV/AIDS, road injury, lower respiratory infections, malaria, drowning and diarrhoeal diseases caused many deaths.
Teachers are the key personnel in schools to look after the health of school children, as they are a rich local resource. Teachers are the key personnel in schools to look after the health of school children, as they are a rich local resource, acceptable personnel to the students as well as to the community and other local agencies like NGOs.

If they are equipped with proper knowledge regarding school health, it will help in developing and maintaining his or her own health as well as of the students. Teachers can provide health education to school children, assess the school environment for better health outcomes, provide health care services and help in the maintenance of student health records. Schools have a responsibility to educate their students and foster among them healthy and hygienic behaviour. Students should be educated on the health risks they face at school and how to protect themselves and others against diseases and other forms of ill-health by adopting health-promoting and health-risking habits and practices. But according to the studies, school teachers are ill-equipped with adequate knowledge regarding school health and without adequate knowledge, it is impossible to take care of the health promotion of students. As per available literature, there is a scarcity of data regarding the knowledge among school teachers regarding school health services. So this study was conducted to assess the status of knowledge of school health services among designated school teachers.

**METHODS**

This community-based cross-sectional study was carried out from June 2018 to June 2020 in the department of Community Medicine, Bhagat Phool Singh Government Medical College for Women, Khanpur Kalan, Sonipat district, Haryana. This study was done among designated schoolteachers for school health in both government and private schools of Haryana, a northern state of India.

**Sample size**

This was a part of a larger study. The sample size was calculated using Cochran’s formula, taking prevalence of the adequate environmental and sanitary conditions in the previous study 50% at 95% CI and 15% permissible error, the sample size obtained was ≈ 50.

One designated schoolteacher for school health from each sampled school was included in this study to form a sample size of 50 schoolteachers.

**Sampling technique**

Three-stage random sampling technique using PPS (Probability Proportional to Size) was adopted for the present study. In stage I one district that is, Sonipat, was selected randomly from a list of 22 district of Haryana a northern state of India.

Two educational blocks were selected using simple random sampling in Stage II. After which I9 government and 31 private schools were selected from the sampled educational blocks by PPS in stage III. One schoolteacher designated for school health was included from each sampled school.

**Inclusions criteria**

It comprises designated schoolteachers for school health from schools located in the district Sonipat, Haryana which were functional in the last five years and granted permission for the study.

**Exclusions criteria**

Schools that were shut down/ non-functional, primary schools and teachers not involved in school health services were excluded.

**Study tools and data management**

The data were collected using a pretested, structured self-administered questionnaire from one schoolteacher of each sampled school. The tool was prepared to collect the data including gender, age, experience of teaching, training status and level of knowledge for school health among designated school teachers. The knowledge was tested by asking multiple-choice questions on various aspects of school health which includes environmental and sanitary conditions in the school, hygiene of students, communicable diseases, non-communicable diseases and health education at school.

A pilot study was conducted among ten school teachers who were not included in the final sample size. Collected data were entered in Microsoft excel version 2019, coding and tabulation was done. The level of teacher’s knowledge regarding school health was graded as adequate (≥75%), moderately adequate (50-74.9%) and inadequate (<50%).

**Ethical consideration**

An informed written consent was obtained from each participant. It was told that participation in this study was voluntary and they can withdraw from the study at any time in between and there won’t be any administrative consequences to them. To maintain the anonymity, codes were given to the schoolteachers.

**Statistical analysis**

Percentage and proportion were calculated for qualitative data. A $\chi^2$ test was used for the categorical variable. SPSS software was used for statistical analyses. The p-value <0.05 was considered statistically significant.
RESULTS

We observed that 19 (38%) participants were from government and 31 (62%) were from private schools. Twenty nine (58%) participants were from rural schools and 21 (42%) participants were from urban schools. In the age distribution, 19 (38%) participants were lying in the age group of 41-50 years, 18 (36%) participants were in the age group of 31-40 years, eight (16%) of the participants were in the age group of 25-30 years and 10% of the participants were of more than 50 years.

We observed that mean age of the participants was 41.64±10.3 years, which was observed to be 43.58±6.94 years among participants from government school and 36.45±10.89 years among participants of private schools. Largest proportion (63.1%) of participants in government school were above the age of 40 years. While among private school majority of the participants (61.3%) were below the 40 years of age. Among all participants, 46% were male participants while 54% were female.

Among all, 48% of participants were having less than ten years of experience, 34% were having experience between 11-20 years, 16% of participants were having experience between 21-30 years and only 2% of participants had more than 31 years of experience. We found that mean years of experience was 12.92±7.9 years which was 13.26±6.6 years among participants of government schools and 12.71±8.69 years among participants of private schools. 22% of participants had training regarding school health services while the rest didn’t (Table 1).

The knowledge of designated school teachers regarding school health services was tested in the schools of the study area. We observed that only 11 (22%) participants answered correctly regarding the adequate ratio of students per class in schools, five (10%) participants for the number of students per latrine/toilet ratio, 14 (28%) participants for adequate lighting of a room in the school. Only one (2%) participant responded correctly about adequate classroom furniture, nine (18%) participants had knowledge about factors included in a school environment and sanitation, 43 (86%) participants answered correctly about disease due to mosquitoes, 15 (30%) participants answered correctly the full form of WASH.

29 (58%) participants answered correctly about the guidelines on handwashing, 27 (54%) participants answered correctly about the types of sanitary disposal, 34 (68%) participants answered correctly about the disposal method for sanitary pads in school, 35 (70%) participants answered correctly about the diseases which can be prevented by proper sanitation, 24 (48%) participants answered correctly regarding communicable diseases related to impure water. 14 (28%) participants answered correctly about the responsibilities of teachers regarding health check-up of students, 32 (64%) participants answered correctly about the health education topics for school level (Table 2). It was observed that, regarding school health 40% of participants had moderately adequate knowledge. It was observed to be more among participants of government schools (57.9%) than private schools (29%), while 60% of participants had inadequate knowledge which was 42.1% among government and 71% among participants of private schools (p=0.04) (Table 3).

International Journal of Community Medicine and Public Health | January 2021 | Vol 8 | Issue 1 | Page 362
Level of moderately adequate knowledge was observed to be more among participants of rural schools as compared to the urban schools (p=0.82), among participants of government schools as compared to the participants of private schools. (p=0.04), among participants of the age group of 41-50 years. (p=0.94), among participants with experience of 21-30 years (p value=0.46), among females as compared to the males (p value=0.91) and among trained participants as compared to untrained participants for school health (p=0.26) (Table 4).

**DISCUSSION**

This study was conducted to know the status of knowledge regarding school health services among schoolteachers in schools of a northern Indian state. As far as ownership was concerned the proportion of private school was higher in the study area so we observed that majority of the participants were from private schools (62%), while Abubakar AU9 has found that the majority of the participants (67.8%) were from government schools. As the proportion of schools located in rural area was more in the study area, we observed that majority of the participants were from rural schools (58%), similarly a study by Hun et al found that most of the teachers were from rural schools (69.1%). A higher proportion of private schools were observed to be more in a rural area, may be because of cheaper land in areas located outside the municipality limit. In our study, female participants (54%) outnumbered the male participants (38%). A similar trend but a higher proportion of females teachers was observed by Hun et al (91.8%), and Saadia et al (69.3%) that most of the participants in that study were females. Contrarily Abubakar et al has reported that the majority of the participants were males (79.3%) in his study area. We observed that mean age of participants was 41.64±10.3 years. It was 43.58±6.94 years among participants from government school and 36.45±10.89 years among participants of private schools. Majority of the participants (38%) were in the age group of 41-50 years (52.6% from government and 29% from private). A study by Gowri et al found that most of them (43.8%) were in the age group of 31-40 years and Saadia et al (45.5%) and Abubakar AU9 (37.9%) has found that the majority of the participants were of the age group of 30-39 years. We observed that mean years of experience was 12.92±7.9 years which was 13.26±6.6 years among participants of government schools and 12.71±8.69 years among participants of private schools. Majority (48%) of the participants were having less than ten years of experience. A higher proportion was observed by Gowri et al (85.3%) and Saadia et al (59.2%) that majority of the teachers were having less than ten years of experience. Abubakar AU has found that the majority of the participants (36.4%) were having experience of 10-19 years.

We observed that the proportion of younger teachers i.e. less than 40-year age, was more among private schools as compare to participants of government schools. But length of experience was almost same in both government and private schools which showed that people initially served in private schools and later when they got opportunity, they joined the government schools. This also points that job opportunity in government schools is shrinking for younger generations.

We observed that 22% of participants had training regarding components of school health, which was more than (7.6%) that reported by Chavan et al.11 A lower level of training has clearly been reflecting in knowledge status of schoolteachers regarding various aspect of school health services. Regarding the adequate ratio of students per class in schools, only 11 (22%) participants answered correctly, five (10%) participants answered correctly for the number of students per latrine/toilet ratio, 14 (28%) participants answered correctly for adequate lighting of a room in the school.

Only one (2%) participant responded correctly about adequate classroom furniture, 27 (54%) participants answered correctly about the types of sanitary disposal, 34 (68%) participants answered correctly about the disposal method for sanitary pads in school, nine (18%) participants had knowledge about factors included in a school environment and sanitation, while a higher proportion was observed by Saadia et al, that 66% participants had knowledge for sanitation and 31.8% had knowledge for a supportive environment.

We observed that 43 (86) % participants answered correctly about disease due to mosquitoes, 15 (30%) participants answered correctly about the full form of WASH, 29 (58%) participants answered correctly about the guidelines on handwashing, 35 (70%) participants answered correctly about the diseases which can be prevented by proper sanitation, 24 (48%) participants answered correctly regarding communicable diseases related to impure water, 14 (28%) participants answered correctly about the responsibilities of teachers regarding health check-up of students. A study by Saadia et al has found that 74.1 participants had knowledge regarding the periodic medical examination of students. We observed that 32 (64%) participants answered correctly about the health education topics for the school level. Saadia et al has found that 35.8% of participants had knowledge regarding health issues affecting the school community.

On summing up the various aspect of knowledge on school health services we concluded that none of the participants had adequate knowledge (75% score), 40% of participants had moderately adequate knowledge (50-74.9% score) which was 57.9% among participants of government schools and 29% among participants of private schools.
While 60% of participants had inadequate knowledge (<50% score) which 42.1% among participants of government schools and 71% among participants of private schools. (p-value=0.04). A study by Adebayo et al found that 84.6% of teachers were having inadequate knowledge regarding school health services which was similar in participants of rural and urban schools. The findings of the present study are better than the findings of Gowri et al where 78% of school teachers did not have adequate knowledge, 22% had moderately adequate knowledge and none of the teachers had adequate knowledge regarding the health care of school children. Abubakar et al has found that only 8% of participants were having a good level of knowledge. This highlights the inadequacy of training regarding school health service among schoolteachers.

We observed that level of moderately adequate knowledge was observed to be higher among 44.4% of participants of the age group of 31-40 years. (p-value=0.94), 62.5% participants with experience of 21-30 years of age (p-value=0.46), 40.7% females participants as compared to the males (p-value=0.91), 41.4% participants from rural schools as compared to the urban schools (p-value=0.82).

The difference observed among participants of government schools as compared to the private schools was observed to be statistical significant. (p-value=0.04). Gowri et al has found that there was a statistically significant association between the school teacher’s knowledge with the education and year of teaching experience and there was no statistically significant association between teacher’s knowledge with the age and sex of the participants.

A study by Htun et al found that being teachers from urban areas, over 50 years of age, with service duration of 20-24 years, are found to be statistically significantly associated with higher levels of knowledge. Without adequate knowledge, we can’t expect the schoolteachers to provide a quality health service at schools. This study was conducted among school teachers designated to provide school health services represents a good sample of schools which includes government and private schools in their proportion. Study has also included schools from both rural and urban areas.

Study has not reported any statistically significant difference among teacher strained for School Health Services and the untrained teachers. This strongly points towards the inadequacy and ineffectiveness of the training if any provided to the teachers designated for the School Health Services in the study area.

CONCLUSION

“What the mind doesn’t know, eyes do not see”. Knowledge of school health services is a prerequisite for providing school health services by the designated schoolteachers but the problem of inadequacy of knowledge for school health services was widespread. If schoolteachers won’t see any problem, it will remain unaddressed and thus adversely affects the school children’s health.

Recommendations

It is recommended that the government should make school health training a part of teachers’ educational curriculum. And equipped with desired level of knowledge and skills. This may go long way in approving health of the school children in particular and in the community at large.

ACKNOWLEDGEMENTS

Authors would like to thank ICMR for providing the financial assistance, to District Education Officer, Sonepat, all the school teachers and Dr. Nidhi for their support in the study.

Funding: Financial assistance was provided by ICMR vide letter no. 32/July-2019/PG-Thesis-HRD (25) dated: 30th July 2019.

Conflict of interest: None declared

Ethical approval: The study was approved by the Institutional Ethics Committee
