Abstract—We study a class of distributed hypothesis testing against conditional independence problems. Under the criterion that stipulates minimization of the Type II error rate subject to a (constant) upper bound \( \epsilon \) on the Type I error rate, we characterize the set of encoding rates and exponent for both discrete memoryless and memoryless vector Gaussian settings.

I. INTRODUCTION

Consider the multiterminal detection system shown in Figure 1. In this problem, a memoryless vector source \((X,Y_0,Y_1,...,Y_K)\), \(K \geq 1\), has joint distribution that depends on two hypotheses, a null hypothesis \(H_0\) and an alternate hypothesis \(H_1\). A detector that observes directly the pair \((X,Y_0)\) but only receives summary information of the observations \((Y_1,...,Y_K)\) determines which of the two hypotheses is true. Specifically, Encoder \(k\), \(1 \leq k \leq K\), which observes an i.i.d. string \(Y_k^n\), sends a message \(M_k\) to the detector a finite rate of \(R_k\) bits per observation over a noise-free channel; and the detector makes its decision between the two hypotheses on the basis of the received messages \((M_1,...,M_K)\) as well as the available pair \((X^n,Y_0^n)\). In doing so, the detector can make two types of error: Type I error (guessing \(H_1\) while \(H_0\) is true) and Type II error (guessing \(H_0\) while \(H_1\) is true). The type II error probability decreases exponentially fast with the size \(n\) of the i.i.d. strings, say with an exponent \(E_k\); and, classically, one is interested in characterizing the set of achievable rate-exponent tuples \((R_1,...,R_K,E)\) in the regime in which the probability of the Type I error is kept below a prescribed small value \(\epsilon\). This problem, which was first introduced by Berger [1], and then studied further in [2–4], arises naturally in many applications (for recent developments on this topic, the reader may refer to [5]–[11] and references therein). Its theoretical understanding, however, is far from complete, even from seemingly simple instances of it.

![Fig. 1. Distributed hypothesis testing against conditional independence.](image)

One important such instances was studied by Rahman and Wagner in [12]. In [12], the two hypotheses are such that \(X\) and \((Y_1,\ldots,Y_K)\) are correlated conditionally given \(Y_0\) under the null hypothesis \(H_0\); and they are independent conditionally given \(Y_0\) under the alternate hypothesis \(H_1\), i.e.,

\[
H_0 : P_{X,Y_0,Y_1,\ldots,Y_K} = P_{X|Y_0}P_{Y_0}P_{Y_1,\ldots,Y_K|Y_0} \quad (1a)
\]

\[
H_1 : Q_{X,Y_0,Y_1,\ldots,Y_K} = P_{Y_0}P_{X|Y_0}P_{Y_1,\ldots,Y_K|Y_0}. \quad (1b)
\]

Note that \((Y_0,Y_1,\ldots,Y_K)\) and \((Y_0,X)\) have the same distributions under both hypotheses; and the multiterminal problem [1] is a generalization of the single-encoder test against independence studied by Ahlswede and Csiszar in [2]. For the problem [1] Rahman and Wagner provided inner and outer bounds on the rate-exponent region which do not match in general (see [12, Theorem 1] for the inner bound and [12, Theorem 2] for the outer bound). The inner bound of [12, Theorem 1] is based on a scheme, named Quantize-Bin-Test scheme therein, that is similar to the Berger-Tung-distributed source coding scheme [13, 14].

In this paper, we study a class of the hypothesis testing problem [1] obtained by restricting the joint distribution of the variables under the null hypothesis to satisfy the Markov chain

\[
Y_S \rightarrow (X,Y_0) \rightarrow Y_S^c \quad \forall S \subsetneq K := \{1,\ldots,K\} \quad (2)
\]
i.e., the encoders’ observations \(\{Y_k\}_{k \in K}\) are independent conditionally given \((X,Y_0)\) under \(H_0\). We investigate both discrete memoryless (DM) and memoryless vector Gaussian models. For the DM setting, we provide a converse proof and show that it is achieved using the Quantize-Bin-Test scheme of [12, Theorem 1]. Our converse proof is inspired by that of the rate-distortion region of the Chief-Executive Officer (CEO) problem under logarithmic loss of Courtade and Weissman [15, Theorem 10]. We note that, prior to this work, for general distributions under the null hypothesis (i.e., without the Markov chain [2] under this hypothesis) the optimality of the Quantize-Bin-Test scheme of [12, Theorem 1] for the problem of testing against conditional independence was known only for the special case of a single encoder, i.e., \(K = 1\), (see [12, Theorem 3]), a result which can also be recovered from our result in this paper.

For the vector Gaussian setting too we provide a full characterization of the rate-exponent region. For the proof of the converse of this result, we obtain an outer bound by evaluating our outer bound the DM model by means of a technique that relies on the de Bruijn identity and the properties of Fisher information. In doing so, we show that the Quantize-Bin-Scheme of [12, Theorem 1] with Gaussian test channels and time-sharing is optimal, thus providing

1In fact, the model of [12] also involves a random variable \(Y_{K+1}\), which is chosen here to be deterministic as it is not relevant for the analysis and discussion that will follow in this paper (see Remark 2).
what appears to be the first optimality result for the Gaussian hypothesis testing against conditional independence problem in the vector case even for the single-encoder case, i.e., \( K = 1 \).

### A. Notation

Throughout this paper, we use the following notation. Upper case letters are used to denote random variables, e.g., \( X \); lower case letters are used to denote realizations of random variables, e.g., \( x \); and calligraphic letters denote sets, e.g., \( \mathcal{X} \). The cardinality of a set \( X \) is denoted by \(|X|\). The closure of a set \( A \) is denoted by \( \bar{A} \). The length-\( n \) sequence \((X_1, \ldots, X_n)\) is denoted as \( X^n \); and, for integers \( j \) and \( k \) such that \( 1 \leq j \leq k \leq n \), the subsequence \((X_k, X_{k+1}, \ldots, X_j)\) is denoted as \( X_{j:k}^k \). Probability mass functions (pmfs) are denoted by \( P_X(x) \equiv P\{X = x\} \); and, sometimes, for short, as \( p(x) \). We use \( \mathcal{P}(X) \) to denote the set of discrete probability distributions on \( X \). Boldface upper case letters denote vectors or matrices, e.g., \( X \), where context should make the distinction clear. For an integer \( K \geq 1 \), we denote the set of integers smaller or equal \( K \) as \( \mathcal{K} = \{ k \in \mathbb{N} \mid 1 \leq k \leq K \} \). For a set of integers \( S \subseteq \mathcal{K} \), the complementary set of \( S \) is denoted by \( S^c \), i.e., \( S^c = \{ k \in \mathbb{N} \mid k \in \mathcal{K} \setminus S \} \). Sometimes, for convenience we will need to define \( \bar{S} \) as \( \bar{S} = \{ 0 \} \cup S^c \). For a set of integers \( S \subseteq \mathcal{K} \); the notation \( X_S \) designates the set of random variables \( \{X_k\}_{k \in S} \) with indices in the set \( S \), i.e., \( X_S = \{X_k\}_{k \in S} \). We denote the covariance of a zero mean, complex-valued, vector \( X \) by \( \Sigma_X = \mathbb{E}[XX^*] \), where \((\cdot)^*\) indicates conjugate transpose. Similarly, we denote the cross-correlation of two zero-mean vectors \( X \) and \( Y \) as \( \Sigma_{X,Y} = \mathbb{E}[XY^*] \), and the conditional correlation matrix of \( X \) given \( Y \) as \( \Sigma_{X|Y} = \mathbb{E}[(X - \mathbb{E}[X|Y])(X - \mathbb{E}[X|Y])^*] \), i.e., \( \Sigma_{X|Y} = \Sigma_X - \Sigma_X Y \Sigma_Y^{-1} \Sigma_Y X \). For matrices \( A \) and \( B \), the notation \( \text{diag}(A, B) \) denotes the block diagonal matrix whose diagonal elements are the matrices \( A \) and \( B \) and its off-diagonal elements are the all zero matrices. Also, for a set of integers \( J \subseteq \mathbb{N} \) and a family of matrices \( \{A_i\}_{i \in J} \) of the same size, the notation \( A_J \) is used to denote the (super) matrix obtained by concatenating vertically the matrices \( \{A_i\}_{i \in J} \), where the indices are in the ascending order, e.g., \( A_{\{0,2\}} = [A_0^T, A_2^T]^T \).

### II. Problem Formulation

Consider a \((K + 2)\)-dimensional memoryless source \((X, Y_0, Y_1, \ldots, Y_K)\) with finite alphabet \( \mathcal{X} \times \mathcal{Y}_0 \times \mathcal{Y}_1 \times \ldots \times \mathcal{Y}_K \). The joint probability mass function (pmf) of \((X, Y_0, Y_1, \ldots, Y_K)\) is assumed to be determined by a hypothesis \( H \) that takes one of two values, a null hypothesis \( H_0 \) and an alternate hypothesis \( H_1 \). Specifically, \( X \) and \((Y_0, Y_1, Y_2, \ldots, Y_K)\) are correlated under the null hypothesis \( H_0 \), with their joint distribution assumed to satisfy the Markov chain

\[
Y_0 \rightarrow (X, Y_0) \rightarrow Y_{S^c} \quad \forall S \subseteq \mathcal{K} := \{1, \ldots, K\} \quad (3)
\]

under this hypothesis; and \( X \) and \((Y_1, Y_2, \ldots, Y_K)\) are independent conditionally given \( Y_0 \) under the alternate hypothesis \( H_1 \), i.e.,

\[
H_0 : P_{X,Y_0,Y_1 \ldots Y_K} = P_X P_{Y_0|X} P_{Y_1 \ldots Y_K|Y_0} \quad (4a)
\]

\[
H_1 : Q_{X,Y_0,Y_1 \ldots Y_K} = P_{X|Y_0} P_{Y_1 \ldots Y_K|Y_0} \quad (4b)
\]

Let now \( \{(X_1, Y_0, Y_1, \ldots, Y_K)\}_{i=1}^n \) be a sequence of \( n \) independent copies of \((X, Y_0, Y_1, \ldots, Y_K)\), and consider the detection system shown in Figure 1. Here, there are \( K \) sensors and one detector. Sensor \( k \in \mathcal{K} \) observes the memoryless source component \( Y_{k}^n \) and sends a message \( M_k = \phi_k^{(n)}(Y_{k}^n) \) to the detector, where the mapping

\[
\phi_k^{(n)} : Y_{k}^n \rightarrow \{1, \ldots, M_k^{(n)}\} \quad (5)
\]

designates the encoding operation at this sensor. The detector observes the pair \((X^n, Y_0^n)\) and uses them, as well as the messages \( \{M_1, \ldots, M_K\} \) gotten from the sensors, to make a decision between the two hypotheses, based on a decision rule

\[
\psi^{(n)} : \{1, \ldots, M_1^{(n)}\} \times \ldots \times \{1, \ldots, M_K^{(n)}\} \times X^n \times Y_0^n \rightarrow \{H_0, H_1\} \quad (6)
\]

The mapping \( \psi^{(n)} \) is such that \( \psi^{(n)}(m_1, \ldots, m_K, x^n, y_0^n) = H_0 \) if \((m_1, \ldots, m_K, x^n, y_0^n) \in A_n \) and \( H_1 \) otherwise, with

\[
A_n \subseteq \bigcap_{k=1}^n \{1, \ldots, M_k^{(n)}\} \times X^n \times Y_0^n
\]

designating the acceptance region for \( H_0 \). The encoders \( \{\phi_k^{(n)}\}_{k=1}^K \) and the detector \( \psi^{(n)} \) are such that the Type I error probability does not exceed a prescribed level \( \epsilon \in [0, 1] \), i.e.,

\[
P_{\psi^{(n)}}(Y_0^n, \ldots, Y_K^n, X^n, Y_0^n | A_n) \leq \epsilon \quad (7)
\]

and the Type II error probability does not exceed \( \beta \), i.e.,

\[
Q_{\psi^{(n)}}(Y_0^n, \ldots, Y_K^n, X^n, Y_0^n | A_n) \leq \beta \quad (8)
\]

**Definition 1.** A rate-exponent tuple \((R_1, \ldots, R_K, E)\) is achievable for a fixed \(\epsilon \in [0, 1] \) if for any positive \(\delta\) and sufficiently large \(n\) there exist encoders \( \{\phi_k^{(n)}\}_{k=1}^K \) and a detector \( \psi^{(n)} \) such that

\[
\frac{1}{n} \log M_k^{(n)} \leq R_k + \delta \quad \text{for all } k \in \mathcal{K}, \quad (9a)
\]

\[
-\frac{1}{n} \log \beta \geq E - \delta. \quad (9b)
\]

**The rate-exponent region** \( \mathcal{R}_{HT} \) is defined as

\[
\mathcal{R}_{HT} := \bigcap_{\epsilon > 0} \mathcal{R}_{HT, \epsilon}, \quad (10)
\]

where \( \mathcal{R}_{HT, \epsilon} \) is the set of all achievable rate-exponent vectors for a fixed \(\epsilon \in [0, 1] \).

### III. DISCRETE MEMORYLESS CASE

We start with an entropy characterization of the rate-exponent region \( \mathcal{R}_{HT} \) as defined by \(10\). Let

\[
\mathcal{R}^* = \bigcup_{n=1}^\infty \bigcup_{\{\phi_k^{(n)}\}_{k \in \mathcal{K}}} \mathcal{R}^*(n, \{\phi_k^{(n)}\}_{k \in \mathcal{K}}) \quad (11)
\]

where

\[
\mathcal{R}^*(n, \{\phi_k^{(n)}\}_{k \in \mathcal{K}}) = \left\{ (R_1, \ldots, R_K; E) \text{ s.t.} \right. \quad (12a)
\]

\[
R_k \geq \frac{1}{n} \log |\phi_k^{(n)}(Y_k^n)| \text{ for all } k \in \mathcal{K}, \quad (12b)
\]

\[
E \leq \frac{1}{n} H(\{\phi_k^{(n)}(Y_k^n)\}_{k \in \mathcal{K}}; X^n | Y_0^n) \right\}. \quad (12b)
\]

We have the following proposition the proof of which is essentially similar to that of \([2\text{, Theorem 5}]\); and, hence, is omitted.

**Proposition 1.** \( \mathcal{R}_{HT} = \mathcal{R}^* \).
We now have the following theorem which provides a single-letter characterization of the rate-exponent region $R_{\text{VT}}$.

**Theorem 1.** The rate-exponent region $R_{\text{VT}}$ is given by the union of all non-negative tuples $(R_1, \ldots, R_K, E)$ that satisfy, for all subsets $S \subseteq \mathcal{K}$,

$$E \leq I(U_S; X|Y_0, Q) + \sum_{k \in S} \left( R_k - I(Y_k; U_k|X, Y_0, Q) \right)$$

for some auxiliary random variables $(U_1, \ldots, U_K, Q)$ with distribution $P_{U_1, \ldots, U_K, Q(u_1, \ldots, u_K, q)}$ such that

$$P_{X, Y_0, U_1, \ldots, U_K, Q}(x, y_0, u_1, \ldots, u_K, q) = P_Q(q)P_{X, Y_0}(x, y_0) \prod_{k=1}^K P_{U_k|X, Y_0}(u_k|y_0).$$

(13)

**Proof.** The proof of Theorem 1 is given in Section V.A.

**Remark 1.** As we mentioned in the introduction section, Rahman and Wagner [12] study the hypothesis testing problem of Figure 1. Theorem 1 characterizes the rate-exponent region which do not match in general (see [12, Theorem 1]) is optimal. We consider in [12] are independent condition given $X$, however, the model studied by Rahman and Wagner is restricted to satisfy that, like in our setup (which corresponds to $K=1$), a result which can also be recovered from Theorem 1.

IV. MEMORYLESS VECTOR GAUSSIAN CASE

We now turn to a continuous example of the hypothesis testing problem studied in this paper. Here, $(X, Y_0, Y_1, \ldots, Y_K)$ is a zero-mean Gaussian random vector such that

$$Y_0 = H_0 X + N_0$$

where $H_0 \in \mathbb{C}^{n_0 \times n_2}$, $X \in \mathbb{C}^{n_2}$ and $N_0 \in \mathbb{C}^{n_0}$ are independent Gaussian vectors with zero-mean and covariance matrices $\Sigma_k \succeq 0$ and $\Sigma_0 \succeq 0$, respectively. The vectors $(Y_1, \ldots, Y_K)$ and $X$ are correlated under the null hypothesis $H_0$ and are independent under the alternate hypothesis $H_1$, with

$$H_0 : Y_k = H_k X + N_k, \quad \forall k \in \mathcal{K}$$

(16a)

$$H_1 : (Y_1, \ldots, Y_K) \text{ independent from } X \text{ conditionally given } Y_0.$$  

(16b)

The noise vectors $(N_1, \ldots, N_K)$ are jointly Gaussian with zero mean and covariance matrix $\Sigma_{N_k} \succeq 0$. They are assumed to be independent from $X$ but correlated among them and with $N_0$, with for every $S \subseteq \mathcal{K}$,

$$N_S \sim N_0 \sim N_{S^c}.$$  

(17)

Let $\Sigma_k$ denote the covariance matrix of noise $N_k$, $k \in \mathcal{K}$. Also, let $R_{\text{VG-HT}}$ denote the rate-exponent region of this vector Gaussian hypothesis testing against conditional independence problem.

For convenience, we now introduce the following notation which will be instrumental in what follows. Let, for every set $S \subseteq \mathcal{K}$, the set $S = \{0\} \cup S^c$. Also, for $S \subseteq \mathcal{K}$ and given matrices $(\Omega_k)_{k=1}^K$ such that $0 \preceq \Omega_k \preceq \Sigma_k^{-1}$, let $\Lambda_S$ denote the block-diagonal matrix given by

$$\Lambda_S \triangleq \begin{bmatrix} 0 & \text{diag}((\Sigma_k - \Omega_k \Sigma_k)_{k \in S^c}) \end{bmatrix}$$

(18)

where $0$ in the principal diagonal elements is the $n_0 \times n_0$-all zero matrix.

The following theorem gives an explicit characterization of $R_{\text{VG-HT}}$.

**Theorem 2.** The rate-exponent region $R_{\text{VG-HT}}$ of the vector Gaussian hypothesis testing against conditional independence problem is given by the set of all non-negative tuples $(R_1, \ldots, R_K, E)$ that satisfy, for all subsets $S \subseteq \mathcal{K}$,

$$E \leq \sum_{k \in S} \left( R_k + \log |1 - \Omega_k \Sigma_k| \right) + \log \left| 1 + \Sigma_k H_k^H \Sigma_k^{-1} H_0 \right|$$

$$+ \log \left| 1 + \Sigma_k H_0^H \Sigma_k^{-1} \Lambda_{S^c} \Sigma_k^{-1} \right|$$

(19a)

for matrices $(\Omega_k)_{k=1}^K$ such that $0 \preceq \Omega_k \preceq \Sigma_k^{-1}$, where $S = \{0\} \cup S^c$ and $\Lambda_S$ is given by (18).

**Proof.** The proof of Theorem 2 is given in Section V.B.

In what follows, we elaborate on two special cases of Theorem 2:

i) the one-encoder vector Gaussian testing against conditional independence problem (i.e., $K = 1$) and

ii) the $K$-encoder scalar Gaussian testing against independence problem.

Let us first consider the case $K = 1$. In this case, the Markov chain $(17)$ which is to be satisfied under the null hypothesis is non-restrictive; and Theorem 2 then provides a complete solution of the (general) one-encoder vector Gaussian testing against conditional independence problem. More precisely, in this case the optimal trade-off between rate and Type II error exponent is given by the set of pairs $(R_1, E)$ that satisfy

$$E \leq R_1 + \log |1 - \Omega_1 \Sigma_1|$$

(19a)

$$E \leq \log \left| 1 + \Sigma_k H_k^H \Sigma_k^{-1} \Lambda_{S^c} \Sigma_k^{-1} \right|$$

$$- \log \left| 1 + \Sigma_k H_0^H \Sigma_k^{-1} H_0 \right|,$$

(19b)
for some $n_1 \times n_1$ matrix $\Omega_1$ such that $0 \preceq \Omega_1 \preceq \Sigma^{-1}$, where $H_{(0,1)} = [H_0^T, H_1^T]^T$, $\Sigma_{(0,1)}$ is the covariance matrix of noise $(N_0, N_1)$ and

$$A_{(0,1)} := \begin{bmatrix} 0 & 0 \\ 0 & \Sigma_1 - \Sigma_1 \Omega_1 \Sigma_1 \\ \end{bmatrix}$$

with the $0$ in its principal diagonal denoting the $n_0 \times n_0$ all zero matrix. In particular, for the setting of testing against independence, i.e., $Y_0 = \emptyset$ and the decoder’s task reduced to guessing whether $Y_1$ and $X$ are independent or not, the optimal trade-off expressed by (19) reduces to the set of $(R_1, E)$ pairs that satisfy, for some $n_1 \times n_1$ matrix $\Omega_1$ such that $0 \preceq \Omega_1 \preceq \Sigma^{-1}$,

$$E \leq \min \left\{ R_1 + \log \left| I - \Omega_1 \Sigma_1 \right|, \log \left| I + \Sigma \Omega_1 \Sigma_1 \right| \right\}. \quad (21)$$

Observe that (19) is the counter-part, to the vector Gaussian setting, of the result of [12, Theorem 3] which provides a single-letter formula for the Type II error exponent for the one-encoder DM testing against independence problem. Similarly, (21) is the solution of the vector Gaussian version of the one-encoder DM testing against independence problem which is studied, and solved, by Ahlswede and Csiszar in [2, Theorem 2]. Also, we mention that, perhaps non-intuitive, in the one-encoder vector Gaussian testing against independence problem swapping the roles of $X$ and $Y$ yields the optimal trade-off (19) expressed by Ahlswede and Csiszar in [2, Theorem 2]. Also, we mention that, perhaps non-intuitive, in the one-encoder vector Gaussian testing against independence problem swapping the roles of $X$ and $Y$ yields the optimal trade-off (19) expressed by Ahlswede and Csiszar in [2, Theorem 2].

The connection, which is sometimes misleading, consists in viewing the decoder in the hypothesis testing against independence problem considered here as one that computes a binary-valued function of $(X, Y_1)$. The region $R_{SG-HT}$ as given by (23) can be used to, e.g., characterize the centralized rate region, i.e., the set of rate vectors $(R_1, \ldots, R_K)$ that achieve the centralized Type II error exponent

$$I(Y_1, \ldots, Y_K; X) = \sum_{k=1}^{K} \log \frac{\sigma_X^2}{\sigma_k^2}. \quad (24)$$

We close this section by mentioning that, implicit in Theorem 2, the Quantize-Bin-Test scheme of [12, Theorem 1] with Gaussian test channels and time-sharing is optimal for the vector Gaussian $K$-encoder hypothesis testing against conditional independence problem [16]. Furthermore, we note that Rahman and Wagner also characterized the optimal rate-exponent region of a different Gaussian hypothesis testing against independence problem, called the Gaussian many-help-one hypothesis testing against independence problem therein, in the case of scalar valued sources [12, Theorem 7]. Specialized to the case $K = 1$, the result of Theorem 2 recovers that of [13, Theorem 7] in the case of no helpers; and extends it to vector-valued sources and testing against conditional independence in that case.

### V. PROOFS

#### A. Proof of Theorem 1

1) **Converse part:** Let a non-negative tuple $(R_1, \ldots, R_K, E) \in R_{HT}$ be given. Since $R_{HT} = \mathbb{R}^+$, there must exist a series of non-negative tuples $\{(R_1^{(m)}, \ldots, R_K^{(m)}, E^{(m)})\}_{m \in \mathbb{N}}$ such that

$$(R_1^{(m)}, \ldots, R_K^{(m)}, E^{(m)}) \in \mathbb{R}^+ \quad \text{for all } m \in \mathbb{N}, \quad \lim_{m \to \infty} (R_1^{(m)}, \ldots, R_K^{(m)}, E^{(m)}) = (R_1^*, \ldots, R_K^*, E^*). \quad (25a)$$

Fix $\delta' > 0$. Then, $\exists m_0 \in \mathbb{N}$ such that for all $m \geq m_0$, we have

$$R_k \geq R_k^{(m)} - \delta' \quad \text{for all } k \in K, \quad (26a)$$

$$E \leq E^{(m)} + \delta'. \quad (26b)$$

For $m \geq m_0$, there exist a series $\{n_m\}_{m \in \mathbb{N}}$ and functions $\{\phi_k^{(n_m)}\}_{k \in K}$ such that

$$R_k^{(m)} \geq \frac{1}{n_m} \log |\phi_k^{(n_m)}| \quad \text{for all } k \in K, \quad (27a)$$

$$E^{(m)} \leq \frac{1}{n_m} I(\phi_k^{(n_m)}(Y_k^{n_m})) + X_{n_m}|Y_0^{n_m}). \quad (27b)$$

Combining (26) and (27) we get that for all $m \geq m_0$,

$$R_k \geq \frac{1}{n_m} \log |\phi_k^{(n_m)}(Y_k^{n_m})| - \delta' \quad \text{for all } k \in K, \quad (28a)$$

$$E \leq \frac{1}{n_m} I(\phi_k^{(n_m)}(Y_k^{n_m})) + X_{n_m}|Y_0^{n_m}) + \delta'. \quad (28b)$$

The second inequality of (28) implies that

$$H(X_{n_m}|\phi_k^{(n_m)}(Y_k^{n_m})) \leq n_m (H(X|Y_0) -E) + n_m \delta'. \quad (29)$$

Let $S \subseteq K$ a given subset of $K$, and $J_k := \phi_k^{(n_m)}(Y_k^{n_m})$. Also, define, for $i = 1, \ldots, n_m$, the following auxiliary random variables

$$U_{k,i} := (J_k, Y_k^{-i}), \quad Q_i := (X_{i-1}, X_{i+n_k}, Y_{i-1}, Y_{i+n_k}). \quad (30)$$

This problem is related to the Gaussian many-help-one problem [16-18]. Here, different from the setup of Figure 1, the source $X$ is observed directly by a main encoder who communicates with a detector that observes $Y$ in the aim of making a decision on whether $X$ and $Y$ are independent or not. Also, there are helpers that observe independent noisy versions of $X$ and communicate with the detector in the aim of facilitating that test.
Note that, for all $k \in \mathcal{K}$, it holds that $U_{k,i} \rightarrow Y_{k,i} \rightarrow (X_i, Y_{0,i}) \rightarrow Y_{\mathcal{K}\setminus k,i} \rightarrow U_{\mathcal{K}\setminus k,i}$ is a Markov chain in this order.

We have

$$n_m \sum_{k \in \mathcal{S}} R_k \geq \sum_{k \in \mathcal{S}} H(J_k) \geq H(J_S) \geq H(J_S; J_{S^c}, Y_{n,m})$$

$$(31)$$

$$= I(J_S; X_{n,m} \mid J_{S^c}, Y_{0,n,m}) + I(J_S; Y_{n,m} \mid J_{S^c}, Y_{0,n,m}) = H(X_{n,m} \mid J_{S^c}, Y_{0,n,m}) - H(X_{n,m} \mid J_S, Y_{0,n,m}) + I(J_S; Y_{n,m} \mid J_{S^c}, J_S, Y_{0,n,m})$$

$$(32)$$

$$= H(X_{n,m} \mid J_{S^c}, Y_{0,n,m}) - H(X_{n,m} \mid Y_{0,n,m}) + I(J_S; Y_{n,m} \mid J_{S^c}, Y_{0,n,m}) + n_m E - n_m \delta'$$

$$(33)$$

Notice that $\delta'$ in $(33)$ can be chosen arbitrarily small, a standard time-sharing argument completes the proof of the converse part.

2) Direct part: The achievability follows by applying the Quantize-Bin-Test scheme of Rahman and Wagner [12] Appendix B. Applied to our model, the rate-exponent region achieved by this scheme, which we denote as $\mathcal{R}_{QBT}$, is given by the union of all non-negative rate-exponent tuples $(R_1, \ldots, R_K, E)$ for which

$$\sum_{k \in \mathcal{S}} R_k \geq I(U_S; Y_S \mid U_{S^c}, Y_0, Q), \quad \forall S \subseteq \mathcal{K}, \quad (34a)$$

$$E \leq I(U_S; X \mid Y_0). \quad (34b)$$

Through submodularity arguments that are essentially similar to in [15] Appendix B (see also [19] and [20] Appendix IV), and which we omit here for brevity, the region $\mathcal{R}_{QBT}$ can be shown to be equivalent to the region $\mathcal{R}_{HT}$ as stated in Theorem [1].

B. Proof of Theorem 2

Let an achievable tuple $(R_1, \ldots, R_K, E)$ for the memoryless vector Gaussian hypothesis testing against conditional independence problem of Section [IV] be given. By a standard extension of the result of Theorem [1] to the continuous alphabet case (through standard discretization arguments), there must exist a.r.v. $(U_1, \ldots, U_K, Q)$ with distribution that factorizes as

$$P_{X, Y_0, Y_K, U_K, Q}(x, y_0, y_K, u_K, q) = P_Q(q) P_{Y_K}(y_K) P_{U_K}(u_K | y_K, q). \quad (35)$$

such that for all $S \subseteq \mathcal{K}$,

$$E \leq \sum_{k \in \mathcal{S}} R_k \leq I(U_S; X \mid Y_0, Q) - \sum_{k \in \mathcal{S}} I(Y_k; U_K | X, Y_0, Q). \quad (36)$$

The converse proof of Theorem 2 relies on deriving an upper bound on the RHS of $(36)$. In doing so, we use the technique of [21] Theorem 8 which relies on the de Brujin identity and the properties of Fisher information; and extend the argument to account for the time-sharing variable $Q$ and side information $Y_0$.

For convenience, we first state the following lemma.

**Lemma 1.** [21, 22] Let $(X, Y)$ be a pair of random vectors with pmf $p(x, y)$. We have

$$\log \left(\frac{p(x)}{p(y) \cdot \text{mmse}(x|y)}\right) \leq h(x|y) \leq \log \left(\frac{p(x)}{\text{mmse}(x|y)}\right)$$

where the conditional Fisher information matrix is defined as

$$J(x|y) := E[\nabla \log p(x|y) \nabla \log p(x|y)^t]$$

and the minimum mean squared error (MMSE) matrix is

$$\text{mmse}(x|y) := E[(x - E[\hat{x}|y])(x - E[\hat{x}|y])^t].$$

Fix $q \in \mathcal{Q}$, $S \subseteq \mathcal{Q}$. Also, let $0 \leq \Omega_{k,q} < \Sigma_k^1$ and

$$\text{mmse}(y_k | x, u_k, q) = \Sigma_k - \Omega_{k,q} \Sigma_k \Omega_{k,q}. \quad (37)$$

Such $\Omega_{k,q}$ always exists since

$$0 \leq \text{mmse}(y_k | x, u_k, q) \leq \Sigma_k. \quad (38)$$
Then, we have

\[
I(Y_k; U_k|X, Y_0, Q = q) = \log (|\pi e|) \Sigma_k - h(X_k|X, U_k, Y_0, Q = q)
\]

\[
\geq \log |\Sigma_k| - \log |\text{mmse}(Y_k|X, U_k, Y_0, Q = q)|
\]

\[
= - \log |I - \Omega_k, q_\Sigma_k|
\]

(38)

where (a) is due to Lemma 1 and (b) is due to (37).

Now, let the matrix \( \Lambda_{\Sigma, q} \) be defined as

\[
\Lambda_{\Sigma, q} := \begin{bmatrix} 0 & 0 \\
0 & \text{diag}\{(\Sigma_k - \Sigma_k \Omega_k, q_\Sigma_k)_{k \in S'}\}
\end{bmatrix}
\]

(39)

Then, we have

\[
I(U_{S'}; X|Y_0, Q = q) = h(X|Y_0) - h(X|U_{S'}, Y_0, Q = q)
\]

\[
\leq h(X|Y_0) - \log |(\pi e)J^{-1}(X|U_{S'}, Y_0, q)|
\]

\[
\leq h(X|Y_0) - \log \left| (\pi e) \left( \Sigma_{\Sigma}^{-1} + H_S^T \Sigma_{\Sigma}^{-1} (I - \Lambda_{\Sigma, q} \Sigma_{\Sigma}^{-1}) H_S \right) \right|
\]

(40)

where (a) follows by using Lemma 1 and (b) follows by using the equality

\[
J(X|U_{S'}, Y_0, q) = \Sigma_{\Sigma}^{-1} + H_S^T \Sigma_{\Sigma}^{-1} (I - \Lambda_{\Sigma, q} \Sigma_{\Sigma}^{-1}) H_S.
\]

(41)

the proof of which uses a connection between MMSE and Fisher information as shown next. More precisely, for the proof of \([41]\) first recall de Brujin identity which relates Fisher information and MMSE.

**Lemma 2.** \([27]\) Let \((V_1, V_2)\) be a random vector with finite second moments and \(Z \sim CN(0, \Sigma_z)\) independent of \((V_1, V_2)\). Then

\[
\text{mmse}(V_2|V_1, V_2 + Z) = \Sigma_z - \Sigma_z J(V_2 + Z|V_1) \Sigma_z.
\]

From MMSE estimation of Gaussian random vectors, we have

\[
X = E[X|Y_S] + W_S = G_S Y_S + W_S
\]

(42)

where \(G_S := \Sigma_{w_S} H_S^T \Sigma_{n_S}^{-1}\), and \(W_S \sim CN(0, \Sigma_{w_S})\) is a Gaussian vector that is independent of \(Y_S\) and

\[
\Sigma_{w_S}^{-1} := \Sigma_{\Sigma}^{-1} + H_S^T \Sigma_{\Sigma}^{-1} H_S.
\]

(43)

Next, we show that the cross-terms of \(\text{mmse}(Y_S|X, U_{S'}, Y_0, q)\) are zero. For \(i \in S'\) and \(j \neq i\), we have

\[
E\left[(Y_i - E[Y_i|X, U_{S'}, Y_0, q])(Y_j - E[Y_j|X, U_{S'}, Y_0, q])^T\right]
\]

\[
\geq E\left[E(Y_i - E[Y_i|X, U_{S'}, Y_0, q])\right]
\]

\[
\times E(Y_j - E[Y_j|X, U_{S'}, Y_0, q])^T|X, Y_0]
\]

\[
\geq E\left[E(Y_i - E[Y_i|X, U_{S'}, Y_0, q]|X, Y_0]\right]
\]

\[
\times E(Y_j - E[Y_j|X, U_{S'}, Y_0, q]|X, Y_0)^T]
\]

(44)

where (a) is due to the law of total expectation; (b) is due to the Markov chain \(Y_k \rightarrow (X, Y_0) \rightarrow Y_{k+1}\). Then, we have

\[
\text{mmse}(G_S Y_S|X, U_{S'}, Y_0, q)
\]

\[
= G_S \text{mmse}(Y_S|X, U_{S'}, Y_0, q) G_S^T
\]

\[
\geq \text{diag}(\text{mmse}(Y_k|X, U_{S'}, Y_0, q))_{k \in S'}
\]

(45)

where (a) follows since the cross-terms are zero as shown in \([44]\); and (b) follows due to (37) and the definition of \(\Lambda_{\Sigma, q}\) given in (39).

We note that \(W_S\) is independent of \(Y_S = (Y_0, Y_{S'});\) and, with the Markov chain \(U_{S'} \rightarrow Y_{S'} \rightarrow (X, Y_0)\), which itself implies \(U_{S'} \rightarrow Y_{S'} \rightarrow (X, Y_0, W_S)\), this yields that \(W_S\) is independent of \(U_{S'}\). Thus, \(W_S\) is independent of \((G_S Y_S, U_{S'}, Y_0, Q)\). Applying Lemma 2 with \(V_1 := (U_{S'}, Y_0, Q)\), \(V_2 := G_S Y_S\) and \(Z := W_S\), we get

\[
J(X|U_{S'}, Y_0, Q) = \Sigma_{w_S}^{-1} - \Sigma_{w_S}^{-1} \text{mmse}(G_S Y_S|X, U_{S'}, Y_0, Q) \Sigma_{w_S}^{-1}
\]

\[
\geq \Sigma_{w_S}^{-1} - \Sigma_{w_S}^{-1} G_S \Lambda_{\Sigma, q} G_S^T \Sigma_{w_S}^{-1}
\]

(46)

\[
= \Sigma_{w_S}^{-1} + H_S^T \Sigma_{n_S}^{-1} \Lambda_{\Sigma, q} \Sigma_{n_S}^{-1} H_S
\]

where (a) is due to \([45]\) and (b) follows due to the definitions of \(\Sigma_{w_S}^{-1}\) and \(G_S\).

Next, we average the expression in \([38]\) and \([40]\) over the time-sharing \(Q\) and letting \(\Omega_k := \sum_{q \in Q} p(q) \Omega_{k, q}\), we obtain the lower bound

\[
I(Y_k; U_k|X, Y_0, Q = q) = \sum_{q \in Q} p(q) I(Y_k; U_k|X, Y_0, Q = q)
\]

\[
\geq \sum_{q \in Q} p(q) \log |I - \Omega_{k, q} \Sigma_k|
\]

\[
\geq - \sum_{q \in Q} p(q) \text{log}(I - \nabla_k, q) \Sigma_k
\]

(47)

where (a) follows from \([38]\); and (b) follows from the concavity of the log-det function and Jensen’s Inequality.

Besides, we have

\[
I(U_{S'}; X|Y_0, Q = q) = h(X|Y_0) - \sum_{Q \in Q} p(q) h(X|U_{S'}, Y_0, Q = q)
\]

\[
\leq h(X|Y_0) - \sum_{Q \in Q} p(q) \log |(\pi e) \left( \Sigma_{\Sigma}^{-1} + H_S^T \Sigma_{\Sigma}^{-1} (I - \Lambda_{\Sigma, q} \Sigma_{\Sigma}^{-1}) H_S \right)^{-1}|
\]

\[
\leq h(X|Y_0) - \log |(\pi e) \left( \Sigma_{\Sigma}^{-1} + H_S^T \Sigma_{\Sigma}^{-1} (I - \Lambda_{\Sigma, q} \Sigma_{\Sigma}^{-1}) H_S \right)^{-1}|
\]

(48)

where (a) is due to \([40]\) and (b) is due to the concavity of the log-det function and Jensen’s inequality and the definition of \(\Lambda\) given in \([18]\).
Finally, combining (46) and (47), noting that
\[ \Omega_k = \sum_{q \in Q} p(q) \Omega_{k,q} \preceq \Sigma_k^{-1} \] since \( 0 \preceq \Omega_{k,q} \preceq \Sigma_k^{-1} \), and taking the union over \( \Omega_k \) satisfying \( 0 \preceq \Omega_k \preceq \Sigma_k^{-1} \).
