KEYWORDS
Multi-question approach; Randomized response; Proportional allocation; Relative efficiency.

Abstract. This study proposes optional Randomized Response Technique (RRT) models in a binary response situation. The application of the proposed optional RRT models under stratification is also explored. Gupta et al. [1] introduced an ingenious idea of optional RRT model in which a question may appear sensitive to one respondent while being not sensitive to another. This study focuses on estimating $\pi$, the prevalence of sensitive attribute, $\omega$, the sensitivity level of the underlying sensitive question when the proportion of unrelated innocuous attribute $\pi_o$ is unknown. A new multi-question approach is proposed for estimation of parameters $(\pi, \omega)$. A comparison between the proposed optional RRT models and the corresponding full RRT models is carried out numerically under simple and stratified random sampling.

1. Introduction

Respondents usually either distort the truth or refuse to answer when potentially sensitive questions such as illegal use of drugs, tax evasion, homosexuality, cheating in exams, extra marital affairs, illegal income, or domestic violence are included in surveys. Non-response or false response produces biased estimates; therefore, Randomized Response Technique (RRT) is useful for reducing the bias and procuring reliable data. Warner [2] suggested an ingenious method of RRT to estimate the unknown population prevalence of sensitive attribute ($\pi$). In Warner’s model, a randomly selected proportion $p$ of respondents is asked a sensitive attribute, say $A$, and the remaining proportion $(1-p)$ of respondents are asked complement of the sensitive attribute $A'$. The researcher does not know the respondents’ answers, whether they are of sensitive question or its complement. Greenberg et al. [3] extended the Warner’s model by introducing unrelated innocuous attribute say $X$ as a replacement of $A'$ in their RRT model. Some other developments in RRT result from Chaudhuri and Mukerjee [4], Mahmood et al. [5], Perri [6], Hussain and Shabbir [7], Lee et al. [8], Abdelfatah and Mazlom [9], Tanveer and Singh [10,11], Blair et al. [12], Singh and Gorey [13], Bose [14], and Abid et al. [15].

RRT models can be categorized as full, partial, and optional. In full RRT model, a Randomization Device (RD) is provided to respondents who are requested to respond to the question (i.e., sensitive or non-sensitive) occurring on RD. The element of a truthful response is incorporated in partial RRT model by adding the additional stage or RD. For example, in the two-stage RRT model, the first RD has two options:
(i) Do you belong to the sensitive group?

(ii) Go to the second RD with known probabilities $T$ and $(1 - T)$.

The second RD is exactly the same as that provided in the full RRT model. In the optional RRT model, respondents are requested to provide truthful responses if they consider the question non-sensitive and use the RD if they consider the sensitive question and provides the response after using it. Mangat and Singh [16] and Gupta et al. [1] introduced the partial RRT model and optional RRT model, respectively. The characteristics of optional RRT models were discussed further by Gupta and Shabbir [17], Gupta et al. [18–20], and Chhabra et al. [21]. The purpose of all RRT models is to protect privacy and promote cooperation among respondents.

Researchers remain mostly interested in investigating both the prevalence of sensitive attribute and sensitivity level of the question. To this end, Gupta et al. [22] described a two-step approach to estimating the mean of a sensitive variable and sensitivity level. In this approach, the respondents are asked two separate questions:

- Question 1 is the auxiliary question about whether or not the main research question is sensitive enough for the respondent to opt for a scrambled response;

- Question 2 is the main research question that the respondent answers using an additive optional RRT model.

Silm et al. [23], Chhabra et al. [21], and Narjis and Shabbir [24] discussed some improvement on a two-step approach.

Motivated by Silm et al. [23], we propose optional RRT models for the randomized devices that consist of three types of statements and three techniques proposed by Mahmood et al. [5]. We propose a multi-question approach to estimate the prevalence of sensitive attribute and sensitivity level when an unrelated innocuous attribute is unknown. The basic purpose of this study is to obtain the truthful responses from some proportion of people and promote the efficiency of the models. This paper is organized as follows: Section 2 presents RRT models given by Mahmood et al. [5]. Section 3 introduces a multi-question approach to estimate the parameters of the proposed optional RRT models under Simple Random Sampling With Replacement (SRSWR) and numerically compares it with the RRT models proposed by Mahmood et al. [5]. Section 4 proposes optional RRT models under stratification and numerically compares them with the mentioned RRT models. Finally, Section 5 concludes the paper.

2. Some existing RRT models

This section discusses RRT models from Mahmood et al. [5]. Mahmood et al. [5] introduced three binary unrelated question models to estimate the prevalence of sensitive attribute:

Technique-I: The RD consists of three types of statements:

(i) I belong to group $A$;

(ii) I belong to group $X^c$;

(iii) I belong to group $X$ with probabilities $p_1$, $p_2$, and $p_3$, such that $\sum_{i=1}^{3} p_i = 1$.

The proportion of the unrelated question $\pi_x$ is unknown; thus, to estimate $\pi_x$, another sample of size $n_2$ is required such that $(n_1 + n_2) = n$. The probability of a “Yes” response in the first sample of size $n_1$ respondents is given as follows:

$$\lambda_{M_1} = \pi p_1 + p_2 (1 - \pi_x) + p_3 \pi_x.$$  \(1\)

In the second independent sample of $n_2$ respondents, the question is asked only on the unrelated question $X$ to estimate the proportion $\pi_x$ of the unrelated innocuous attribute. An unbiased estimator for population proportion $\pi$ is given by:

$$\hat{\pi}_{M_1} = \frac{\lambda_{M_1} - p_2 (1 - \hat{\pi}_x) - p_3 \hat{\pi}_x}{p_1},$$  \(2\)

taking $\lambda_{M_1} \sim B(n_1, \lambda_{M_1})$ and $\hat{\pi}_x \sim B(n_2, \pi_x)$. The minimum variance of $\hat{\pi}_{M_1}$ is given by:

$$\text{Var}(\hat{\pi}_{M_1})_{\text{min}} = \frac{\left[\sqrt{\lambda_{M_1} (1 - \lambda_{M_1})} + (p_2 - p_3) \sqrt{\pi_x (1 - \pi_x)}\right]^2}{np_1^2}.$$  \(3\)

The ratio of optimal sample sizes $n_1$ and $n_2$ for the two independent samples is given by:

$$\frac{n_1}{n_2}_{\text{opt}} = \sqrt{\frac{\lambda_{M_1} (1 - \lambda_{M_1})}{(p_2 - p_3)^2 \pi_x (1 - \pi_x)}}.$$  \(4\)

Technique-II: The statement (ii) from Technique-I is simply replaced with “Try once again”. The respondents are advised to repeat the process if the selected card shows “Try once again” statement. In the second draw, if statement “Try once again” reappears, then respondents are asked to say “Yes” irrespective of their actual status. The probability of a “Yes” response in the first sample of size $n_1$ respondents is given as follows:

$$\lambda_{M_1} = (1 + p_2)(p_1 \pi + p_2 \pi_x) + p_2^2.$$  \(5\)
In the second independent sample of \( n_2 \) respondents, the question is asked only on the unrelated question \( X \) to estimate the proportion \( \pi_x \) of the unrelated character. An unbiased estimator of population proportion \( \pi \) is given by:

\[
\hat{\pi}_{M_1} = \frac{\hat{\lambda}_{M_1} - p_2^2 - p_1(1 + p_2)\hat{\pi}_x}{p_1(1 + p_2)}.
\]

(6)

Taking \( \hat{\lambda}_{M_1} \sim B(n_1, \lambda_{M_1}) \) and \( \hat{\pi}_x \sim B(n_2, \pi_x) \). The minimum variance of \( \hat{\pi}_{M_1} \) is given by:

\[
\text{Var}(\hat{\pi}_{M_1})_{\text{min}} = \frac{\left[ \sqrt{\lambda_{M_1}(1-\lambda_{M_1})} + p_1(1 + p_2)\sqrt{\pi_x(1-\pi_x)} \right]^2}{n(p_1(1 + p_2))^2}.
\]

(7)

The ratio of optimal sample sizes \( n_1 \) and \( n_2 \) for the two independent samples is given by:

\[
\left( \frac{n_1}{n_2} \right)_{\text{opt}} = \sqrt{\frac{\lambda_{M_1}(1-\lambda_{M_1})}{p_1(1 + p_2)^2\pi_x(1-\pi_x)}}.
\]

(8)

Technique-III: This Technique differs from Technique-I in the sense that the second statement “I belong to group \( X_2 \)” is simply replaced by the statement “I belong to group \( A \)”. The probability of a “Yes” response in the first sample of size \( n_1 \) respondent is determined as follows:

\[
\lambda_{M_2} = \pi p_1 + p_2(1-\pi) + p_1\pi_x.
\]

(9)

In the second independent sample of \( n_2 \) respondents, the question is asked only on the unrelated question \( X \) to estimate the proportion \( \pi_x \) of the unrelated character. An unbiased estimator for population proportion \( \pi \) is given by:

\[
\hat{\pi}_{M_2} = \frac{\hat{\lambda}_{M_2} - p_2 - p_1\hat{\pi}_x}{p_1 - p_2},
\]

(10)

taking \( \hat{\lambda}_{M_2} \sim B(n_1, \lambda_{M_2}) \) and \( \hat{\pi}_x \sim B(n_2, \pi_x) \). The minimum variance of \( \hat{\pi}_{M_2} \) is given by:

\[
\text{Var}(\hat{\pi}_{M_2})_{\text{min}} = \frac{\left[ \sqrt{\lambda_{M_2}(1-\lambda_{M_2})} + p_1\sqrt{\pi_x(1-\pi_x)} \right]^2}{n(p_1 - p_2)^2}.
\]

(11)

The ratio of optimal sample sizes \( n_1 \) and \( n_2 \) for the two independent samples is given by:

\[
\left( \frac{n_1}{n_2} \right)_{\text{opt}} = \frac{\lambda_{M_2}(1-\lambda_{M_2})}{p_1^2\pi_x(1-\pi_x)}.
\]

(12)

In the next section, a new multi-question approach to estimating the prevalence of sensitive attribute and sensitivity level of modified binary optional RRT models is proposed.

3. Multi-question approach

The main motivation of the multi-question approach is to avoid split sample approach to parameter estimation which requires a larger sample size. To estimate the parameters of RRT models, i.e., unrelated innocuous attributes (\( \pi_x, \pi_y \)), sensitivity level (\( \omega \)), and prevalence of sensitive attribute (\( \pi \)) in the multi-question approach, each respondent is asked more than two separate questions. In the multi-question approach, the Direct Question (DQ) method is applied first to estimate the proportion of unrelated innocuous attributes (\( \hat{\pi}_x, \hat{\pi}_y \)) used in RRT models and, then, to apply two RDs, denoted by \( R_1 \) and \( R_2 \), to estimate the proportion of sensitivity level (\( \hat{\omega} \)) and sensitive attribute (\( \hat{\pi} \)).

3.1. Estimation of sensitivity level

The question about sensitivity is asked via \( R_1 \). In this randomization process, the sensitive question is “Is the main research question sensitive?” It is asked along with an unrelated innocuous question. We use \( R_1 \) device proposed by Greenberg et al. [3]. The probability of getting a “Yes” response to \( R_1 \) is:

\[
\lambda_\omega = \omega p + (1 - p)\pi_y.
\]

(13)

An unbiased estimator of population proportion \( \omega \) is given by:

\[
\hat{\omega} = \frac{\hat{\lambda}_\omega - (1 - p)\hat{\pi}_y}{p}.
\]

(14)

where \( \hat{\lambda}_\omega \) and \( \hat{\pi}_y \) are the proportion of “Yes” answer reported by \( n \) respondents through \( R_1 \) and DQ method in the sample, taking \( \hat{\lambda}_\omega \sim B(n, \lambda_\omega) \) and \( \hat{\pi}_y \sim B(n, \pi_y) \). It is easy to prove that \( \hat{\omega} \) is unbiased for \( \omega \) with the following variance:

\[
\text{Var}(\hat{\omega}) = \frac{1}{p^2} \left[ \frac{\lambda_\omega(1 - \lambda_\omega)}{n} + (1 - p)^2\pi_y(1 - \pi_y) \right].
\]

(15)

3.2. Estimation of prevalence of the sensitive attribute

In this section, we propose three binary optional RRT models to estimate the prevalence of the sensitive attribute. Each respondent is given the option to answer the sensitive question directly if they consider question insensitive or provide the response after using device \( R_2 \).

Technique-I: Optional RRT model

The probability of getting “Yes” response from the proposed binary optional RRT model of Technique-I or the main research question is measured as follows:

\[
\lambda_1 = (1 - \omega)\pi + \omega \left[ p_1 \pi + p_2(1 - \pi_x) + p_0\pi_x \right].
\]

(16)
Solving Eq. (16) for \( \pi \), we have an estimator of \( \pi \) as follows:

\[
\hat{\pi}_{JS_1} = \frac{\hat{\lambda}_1 - \hat{\omega} \{ p_2 - (p_2 - p_3) \hat{\pi}_x \}}{1 - \omega(1 - p_1)}. \tag{17}
\]

where \( \hat{\omega} \) is obtained from Eq. (14) and \( \hat{\lambda}_1 \) and \( \hat{\pi}_x \) are the proportions of “Yes” answers reported by \( n \) respondents through \( R_2 \) and DQ method in the sample, taking \( \hat{\lambda}_1 \sim B(n, \lambda_1) \) and \( \hat{\pi}_x \sim B(n, \pi_x) \). After applying first-order Taylor’s expansion to Eq. (17), we have:

\[
\hat{\pi}_{JS_1} \approx \frac{\lambda_1 - \omega \{ p_2 - (p_2 - p_3) \pi_x \}}{1 - \omega(1 - p_1)} + \frac{\hat{\lambda}_1 - \lambda_1}{1 - \omega(1 - p_1)} + \frac{\omega(p_2 - p_3)(\hat{\pi}_x - \pi_x)}{1 - \omega(1 - p_1)} + \frac{\theta_1 (\hat{\omega} - \omega)}{1 - \omega(1 - p_1)^2}. \tag{18}
\]

where:

\[
\theta_1 = (p_2 - p_3)\pi_x + (1 - p_1)\lambda_1 - p_2.
\]

**Theorem 3.1.** The estimator \( \hat{\pi}_{JS_1} \) is unbiased for \( \pi \) with variance as given below:

\[
\text{Var}(\hat{\pi}_{JS_1}) = \frac{\lambda_1 (1 - \lambda_1) + \omega^2 (p_2 - p_3)^2 \pi_x (1 - \pi_x)}{n(1 - \omega(1 - p_1))^2} + \frac{\theta_1^2 \{ \lambda_\omega (1 - \lambda_\omega) + (1 - p)^2 \pi_y (1 - \pi_y) \}}{np^2 (1 - \omega(1 - p_1))^4}. \tag{19}
\]

**Proof.** Taking expected value on both sides of Eq. (18), we have:

\[
E(\hat{\pi}_{JS_1}) \approx \lambda_1 \frac{1 - \omega \{ p_2 - (p_2 - p_3) \pi_x \}}{1 - \omega(1 - p_1)} + \frac{E(\hat{\lambda}_1) - \lambda_1}{1 - \omega(1 - p_1)} + \frac{\omega(p_2 - p_3)(E(\hat{\pi}_x) - \pi_x)}{1 - \omega(1 - p_1)} + \frac{\theta_1 (E(\hat{\omega}) - \omega)}{1 - \omega(1 - p_1)^2}. \tag{20}
\]

Given that \( E(\hat{\lambda}_1) = \lambda_1 \), \( E(\hat{\pi}_x) = \pi_x \), \( E(\hat{\omega}) = \lambda_\omega \), and \( E(\pi_y) = \pi_y \), Eq. (20) becomes:

\[
E(\hat{\pi}_{JS_1}) \approx \lambda_1 \frac{1 - \omega \{ p_2 - (p_2 - p_3) \pi_x \}}{1 - \omega(1 - p_1)} = \pi. \tag{21}
\]

Thus, \( \hat{\pi}_{JS_1} \) is approximately an unbiased estimator of \( \pi \). Now, applying variance on both sides of Eq. (18), we have:

\[
\text{Var}(\hat{\pi}_{JS_1}) = \left[ \frac{\text{Var}(\hat{\lambda}_1) + \omega^2 (p_2 - p_3)^2 \text{Var}(\hat{\pi}_x)}{1 - \omega(1 - p_1)^2} + \frac{\theta_1^2 \text{Var}(\hat{\omega})}{1 - \omega(1 - p_1)^2} \right]. \tag{22}
\]

Using the fact that \( \text{Var}(\hat{\lambda}_1) = \frac{\lambda_1 (1 - \lambda_1)}{n} \) and \( \text{Var}(\hat{\pi}_x) = \frac{\pi_x(1 - \pi_x)}{n} \) and substituting the values of \( \text{Var}(\hat{\omega}) \) given in Eq. (15), we have Eq. (19) that completes the proof.

**Technique-II optional RRT model**

In \( R_2 \), the respondent has an option to answer the sensitive question directly or using Technique-II of Mahmood et al. [6]. Under \( R_2 \), the probability of getting “Yes” response is:

\[
\lambda_2 = (1 - \omega)\pi + \omega \{ (1 + p_2)(p_1\pi + p_3\pi_x) + \rho_2^2 \}. \tag{23}
\]

Solving Eq. (23) for \( \pi \), we have an estimator of \( \pi \) as follows:

\[
\hat{\pi}_{JS_1} = \frac{\lambda_2 - \hat{\omega} \{ \rho_2^2 + p_3(1 + p_2)\pi_x \}}{1 - \hat{\omega}(1 - p_1)}, \tag{24}
\]

where \( \hat{\omega} \) is obtained from Eq. (14) and \( \lambda_2 \) and \( \pi_x \) are the proportions of “Yes” answers reported by \( n \) respondents through \( R_2 \) and DQ method in the sample by taking \( \lambda_2 \sim B(n, \lambda_2) \) and \( \pi_x \sim B(n, \pi_x) \).

After applying first-order Taylor’s expansion to Eq. (24), we have:

\[
\hat{\pi}_{JS_1} \approx \frac{\lambda_2 - \omega \{ p_2 - (p_2 - p_3) \pi_x \}}{1 - \omega(1 - p_1)} + \frac{\hat{\lambda}_2 - \lambda_2}{1 - \omega(1 - p_1)} + \frac{\omega(p_2 - p_3)(\hat{\pi}_x - \pi_x)}{1 - \omega(1 - p_1)} + \frac{\theta_2 (\hat{\omega} - \omega)}{1 - \omega(1 - p_1)^2}. \tag{25}
\]

where:

\[
\theta_2 = \lambda_2 - \omega \{ p_2 - (p_2 - p_3) \pi_x \} - \lambda_2 (1 + p_2)(\hat{\pi}_x - \pi_x) - \omega (1 - \pi_x) + \omega^2 (p_2 - p_3)^2 \pi_x (1 - \pi_x) + \frac{\theta_1^2 \{ \lambda_\omega (1 - \lambda_\omega) + (1 - p)^2 \pi_y (1 - \pi_y) \}}{np^2 (1 - \omega(1 - p_1))^4}. \tag{26}
\]

**Theorem 3.2.** The estimator \( \hat{\pi}_{JS_1} \) is an unbiased one for \( \pi \) with variance, as given by:

\[
\text{Var}(\hat{\pi}_{JS_1}) = \frac{\lambda_2 (1 - \lambda_2) + \omega^2 (p_2 - p_3)(1 + p_2)\pi_x (1 - \pi_x)}{n[1 - \omega(1 - p_1)]^2} + \frac{\theta_2^2 \{ \lambda_\omega (1 - \lambda_\omega) + (1 - p)^2 \pi_y (1 - \pi_y) \}}{np^2 (1 - \omega(1 - p_1))^4}. \tag{27}
\]

**Proof.** The proof is analogous to that of Theorem 3.1.
Technique-III optional RRT model

The probability of getting “Yes” response from the proposed binary optional RRT model is:

\[
\lambda_3 = (1 - \omega) \pi + \omega \left\{ p_1 \pi + p_2 (1 - \pi) + p_3 \pi_x \right\}.
\] (27)

Solving Eq. (27) for \( \pi \), we have an estimator of \( \pi \) as:

\[
\hat{\pi}_{JS3} = \frac{\lambda_3 - \omega (p_2 + p_3 \pi_x)}{1 - \omega (1 - p_1 + p_2)}.
\] (28)

where \( \hat{\omega} \) is obtained from Eq. (14) and \( \hat{\lambda}_3 \) and \( \hat{\pi}_x \) are the proportions of “Yes” answers reported by \( n \) respondents through \( R_3 \) and DQ method in the sample by taking \( \hat{\lambda}_3 \sim B(n, \lambda_3) \) and \( \hat{\pi}_x \sim B(n, \pi_x) \). After applying first-order Taylor’s expansion to Eq. (28), we have:

\[
\hat{\pi}_{JS3} \approx \left[ \frac{\lambda_3 - \omega (p_2 + p_3 \pi_x)}{1 - \omega (1 - p_1 + p_2)} \right]
\]

\[
+ \frac{\lambda_3 - \lambda_3}{1 - \omega (1 - p_1 + p_2)}
\]

\[
- \frac{\omega p_1 (\hat{\pi}_x - \pi_x)}{1 - \omega (1 - p_1 + p_2)}
\]

\[
+ \frac{\theta_3 (\hat{\omega} - \omega)}{1 - \omega (1 - p_1 + p_2)^2}
\]

where:

\[
\theta_3 = \lambda_3 (1 - p_1 + p_2) - \pi x p_3 - p_2.
\]

Thus, we have the following theorem and its proof is similar to that of Theorem 3.1.

**Theorem 3.3.** The estimator \( \hat{\pi}_{JS3} \) is an unbiased one for \( \pi \) with variance as given by:

\[
\text{Var}(\hat{\pi}_{JS3}) = \frac{\lambda_3 (1 - \lambda_3) + \omega^2 p_3^2 \pi_x (1 - \pi_x)}{n (1 - \omega (1 - p_1 + p_2))^2}
\]

\[
+ \frac{\theta_3^2 \{ \lambda_3 (1 - \lambda_3) + (1 - p)^2 \pi_y (1 - \pi_y) \}}{n \pi^2 (1 - \omega (1 - p_1 + p_2))^4}
\] (30)

3.3. Privacy protection

Lanke [25] proposed a measure of privacy protection based on the idea that a person belonging to the sensitive group \( A \) might be reluctant to reveal the actual group, whereas a member of the complementary group \( A^c \) is expected to be quite willing to announce so. Thus, membership in \( A \) may be embarrassing, except for that in \( A^c \). Thus, the higher the conditional probability \( P(A|R) \), \( R \in \{\text{"Yes"} , \text{"No"}\} \) of belonging to \( A \) given a certain answer \( R \), the greater the embarrassment caused by giving that response. The Lanke measure (hereafter L-measure) is:

\[
L = \max\{P(A|Yes), P(A|No)\}.
\] (31)

However, it takes \( L = P(A|Yes) \) when:

\[
P(A|Yes) - P(A|No) = \frac{\pi [P(Yes|A) - P(Yes)]}{P(Yes)[1 - P(Yes)]} > 0,
\]

that is when:

\[
P(Yes|A) - P(Yes) = (1 - \pi) [P(Yes|A) - P(Yes|A^c)] > 0.
\]

This is true for all the considered RRT models. Therefore, for these randomization procedures, L-measure reduces to:

\[
L = \frac{\pi P(Yes|A)}{P(Yes)}.
\] (32)

The L-measure for the RRT models is given below:

\[
L_{M_1} = \frac{\pi [p_1 + p_2 (1 - \pi_x) + p_3 \pi_x]}{p_1 + p_2 (1 - \pi_x) + p_3 \pi_x},
\] (33)

\[
L_{M_2} = \frac{\pi [(1 + p_2)(p_1 + p_3 \pi_x) + p_3^2]}{(1 + p_2)(p_1 \pi + p_3 \pi_x) + p_3^2},
\] (34)

and:

\[
L_{M_3} = \frac{\pi [p_1 + p_3 \pi_x]}{p_1 + p_2 (1 - \pi) + p_3 \pi_x}.
\] (35)

The L-measure for the proposed optional RRT models is given by:

\[
L_{JS_1} = \frac{\pi [(1 - \omega) + \omega (p_1 + p_2 (1 - \pi_x) + p_3 \pi_x)]}{(1 - \omega) \pi + \omega [p_1 + p_2 (1 - \pi_x) + p_3 \pi_x]},
\] (36)

\[
L_{JS_2} = \frac{\pi [(1 - \omega) + \omega (p_1 + p_2 (1 - \pi_x) + p_3 \pi_x)]}{(1 - \omega) \pi + \omega [p_1 + p_2 (1 - \pi_x) + p_3 \pi_x]},
\] (37)

and:

\[
L_{JS_3} = \frac{\pi [(1 - \omega) + \omega (p_1 + p_3 \pi_x)]}{(1 - \omega) \pi + \omega (p_1 \pi + p_2 (1 - \pi) + p_3 \pi_x)}.
\] (38)

Based on the two RRT models, the model with the smaller value of Lanke [25] privacy measure will be more protective than the other.

If the inequality given below holds true, then the proposed optional RRT models are more protected than competitor models, respectively.

\[
L_{JS_i} - L_{M_i} < 0, \quad i = 1, 2, 3.
\] (39)
Inequality (39) under $L_{JS_2}$ and $L_{M_2}$ is:

$$(1 - \omega)(1 - \pi)(p_2 - (p_2 - p_3)\pi_x) < 0,$$

(40)

Inequality (39) under $L_{JS_1}$ and $L_{M_1}$ is:

$$(1 - \omega)(1 - \pi)(p_2^2 + p_3(1 + p_2)\pi_x) < 0,$$

(41)

Inequality (39) under $L_{JS_2}$ and $L_{M_2}$ is:

$$(1 - \omega)(1 - \pi)(p_2 + p_3\pi_x) < 0.$$

(42)

Privacy of the respondents and gain in efficiency are two alternating measures. The efficiency of the RRT model decreases when the degree of protection to the respondents increases, and vice versa. Theoretically, we observe that the proposed optional RRT models are less protective than competitor RRT models. However, as seen in Figure 1, we observe that for a highly sensitive question ($\omega = 0.9$), the proposed Technique-I optional RRT model and competitor model are equally protected at different values of design parameters. In the case of Technique-II and Technique-III, the same conclusion can be drawn. Chhabra et al. [21] also highlighted that when the asked question is highly sensitive, the proposed optional models achieved the same protection level as the corresponding RRT model. Our conclusion is consistent with that of Chhabra et al. [21].

3.4. Simulation study

In this section, the theoretical and empirical results of the proposed estimators $\hat{\pi}_{JS_i}(i = 1, 2, 3)$ and $\hat{\omega}$ are presented. The parameters $\omega$, $\pi_y$, $p_1$, $p_2$, $p_3 = (1 - p_1 - p_2)$, and $p_3 = 2(1 - p_1)/3$ were allowed to vary, while all others were fixed, $\pi = 0.45$, $\pi_x = 0.85$, $p = 0.7$, $n = 10,000$, and 10,000 trials per simulation. For the simulation of $\hat{\pi}_{JS_i}$ and $\hat{\omega}$, the value of $\omega$ varies from 0.1 to 0.9 with the increment of 0.2. Similarly, the value of $p_1$ varies from 0.2 to 0.8 with the increment of 0.2. Moreover, $\pi_y$ values are chosen as 0.35 and 0.65, respectively.

The simulated results of $\hat{\pi}_{JS_i}(i = 1, 2, 3)$ and $\hat{\omega}$ of optional RRT models are obtained using the multi-question approach which provides a strong support for our earlier findings that $\hat{\pi}_{JS_i}$ and $\hat{\omega}$ are unbiased estimators of $\pi$ and $\omega$, respectively. As shown in Tables 1–3, the simulated values of $E(\hat{\pi})$ and $\text{Var}(\hat{\pi})$ are very close to the corresponding true parameter values of $\pi$ and theoretical values of $\text{Var}(\hat{\pi})$, respectively. The first-order Taylor’s approximation was used to calculate the theoretical values for $\text{Var}(\hat{\pi})$. Similarly, simulated values of $E(\hat{\omega})$ and $\text{Var}(\hat{\omega})$ are very close to the corresponding true parameter values of $\omega$ and theoretical value of $\text{Var}(\hat{\omega})$, respectively. The results presented in Tables 1–3 indicate that the proposed optional RRT models of the multi-question approach are more efficient than competitor RRT models. The results of each model with respect to their competitor RRT models are discussed below:

(i) The findings in Table 1 indicate that Technique-I, i.e., proposed optional RRT model, is more efficient than that proposed by Mahmoud et al. [5]. For example, the results in Table 1 for $\omega = 0.5$, $p_1 = 0.6$, and $\pi_y = 0.35$ show the empirical variance of $\text{Var}(\hat{\pi}) = 0.0004$ and theoretical variance of $\text{Var}(\hat{\pi}) = 0.0004$ for the proposed optional RRT model, respectively. However, the empirical and theoretical variances for the model of Mahmoud et al. [5] include $\text{Var}(\hat{\pi}) = 0.0007$ and $\text{Var}(\hat{\pi}) = 0.0006$, respectively, which demonstrate greater variance than that for the proposed optional RRT model. Similar efficiency patterns are observed at different values of $\omega$, $p_1$, and $\pi_y$;

(ii) The results given in Table 2 show that for $\omega = 0.5$, $p_1 = 0.6$, and $\pi_y = 0.35$, empirical variance of $\text{Var}(\hat{\pi}) = 0.0003$ and theoretical variance of $\text{Var}(\hat{\pi}) = 0.0004$ for the Technique-II optional RRT model are achieved. However, the empirical and theoretical variances of Technique-II of Mahmoud et al. [5] are $\text{Var}(\hat{\pi}) = 0.0005$ and $\text{Var}(\hat{\pi}) = 0.0008$, respectively, which demonstrate that the Technique-II optional RRT model is more efficient than the competitor model. The efficiency pattern remains similar for different values of $\omega$, $p_1$, and $\pi_y$;

(iii) Table 3 demonstrates that for $\omega = 0.5$, $p_1$, and $\pi_y = 0.35$, the empirical and theoretical variances of Technique-III optional RRT model are $\text{Var}(\hat{\pi}) = 0.0004$ and $\text{Var}(\hat{\pi}) = 0.0004$, respectively. The result shows that Technique-III optional RRT model is more efficient than the competitor Technique-III of Mahmoud et al. [5]. The empirical and theoretical variances of Technique-III of Mahmoud et al. [5] are $\text{Var}(\hat{\pi}) = 0.0011$ and $\text{Var}(\hat{\pi}) = 0.0016$, respectively, indicating to its lower efficiency than that of the proposed optional RRT model. The same variance patterns are observed at different values of $\omega$, $p_1$, and $\pi_y$. 
While comparing the results of the proposed optional RRT models with competitor RRT models, one should keep in mind that optional models simultaneously estimate the prevalence of sensitive attribute (π) and sensitivity level (ω). The proposed optional RRT models are characterized by their own merits and demerits; therefore, different models can be used under different scenarios.

4. Stratified random sampling scheme

In this section, the applications of RRT models proposed by Mahmood et al. [5] and the suggested optional RRT models under stratified random sampling are discussed; in this regard, the population consists of $L$ number of strata and the size of each stratum $N_h$ is known. Let the population of size $N$ be divided into disjoint $L$ strata of size $N_h(h = 1, 2, \ldots, L)$ and $W_h = \left( \frac{N_h}{N} \right)$ is the known proportion of population units falling in the $h$th stratum. Let $n_h(\sum_{h=1}^{L} n_h = n)$ respondents be selected by SRSWR and asked to answer “Yes” or “No” according to the RDs.

4.1. The stratified Technique-I of Mahmood et al. [5]

Each respondent in stratum $h$ is provided an RD that consists of three types of statements:

(i) I belong to group $A_h$;

(ii) I belong to group $X_h^c$.
### Table 2. Simulation results for $\pi = 0.45$ when $\text{trials} = 10,000$, $n = 1000$, $\pi_x = 0.85$, $\pi_y = 0.35$, $0.65$, $p = 0.7$ and at various choices of $\omega$, $p_1$, $p_3 = 2(1 - p_1)/3$, and $p_2 = (1 - p_1 - p_3)$.

| $P_1$ | Technique-II Mahmood et al. [5] | Technique-II optional RRT model | $\pi_y = 0.35$ | $\pi_y = 0.65$ |

| 0.6   | 0.5227                           | 0.0005                          | 0.0008         | 0.1000         | 0.2997         | 0.5000         | 0.7002         | 0.0999         | 0.3000         | 0.5003         | 0.7004         | 0.8999         |
| 0.8   | 0.4857                           | 0.0003                          | 0.0004         | 0.1001         | 0.2998         | 0.4998         | 0.7000         | 0.1002         | 0.2996         | 0.4998         | 0.7002         | 0.8998         |

(iii) I belong to group $X_h$ with probabilities $p_{h_1}$, $p_{h_2}$, and $p_{h_3}$, respectively, such that $\sum_{i=1}^n p_{h_i} = 1$.

The proportion of the unrelated question $\pi_{x_h}$ is unknown; therefore, estimating $\pi_{x_h}$ needs another sample of size $n_{h_1}$ such that $(n_{h_1} + n_{h_2} = n_h)$. The probability of a “Yes” response in the first sample of size $n_{h_1}$ respondents is given by:

$$\lambda_{M_{x_1}} = \pi_{h_1}p_{h_1} + p_{h_2}(1 - \pi_{x_1}) + p_{h_3}\pi_{x_1}. \tag{43}$$

In the second independent samples of $n_{h_1}$ respondents, the question is asked only on the unrelated question $X_h$ to estimate the proportion $\pi_{x_h}$ of the unrelated character. An unbiased estimator for the population proportion $\hat{\pi}_{M_{x_1}}$, is given below:

$$\hat{\pi}_{M_{x_1}} = \frac{\lambda_{M_{x_1}}}{n_{h_1}} = \frac{\lambda_{M_{x_1}} - p_{h_1}(1 - \pi_{x_1}) - p_{h_3}\pi_{x_1}}{p_{h_1}}. \tag{44}$$

The variance of $\hat{\pi}_{M_{x_1}}$ is measured as follows:

$$\text{Var}(\hat{\pi}_{M_{x_1}}) = \frac{\sum_{i=1}^L W_i^2}{n_{h_1}}V_{M_{x_1}}. \tag{45}$$

where:

$$V_{M_{x_1}} = \frac{\lambda_{M_{x_1}}(1 - \lambda_{M_{x_1}}) + (p_{h_2} - p_{h_3}) \sqrt{\pi_{x_1}(1 - \pi_{x_1})}}{p_{h_1}^2}. \tag{46}$$
| $P_1$   | Technique-III Mathematical [5] | Technique-III optional RRT model | $\pi_V = 0.35$ | $\pi_V = 0.65$ |

4.2. The stratified Technique-II of Mahmood et al. [5]

The RD provided in each stratum consists of three types of statements:

(i) I belong to group $A_k$;
(ii) Try once again;
(iii) I belong to group $X_k$ with probabilities $p_{x_k} = 0.85$, $p_{x_k} = 0.35$, $p_{x_k} = 0.65$, $p = 0.7$ and at various choices of $\omega$, $p_1$, $p_3 = 2(1 - p_1)/3$, and $p_2 = (1 - p_1 - p_3)$.

If the statement “Try once again” appears on the second trial, then the respondent is requested to report “Yes” irrespective of his/her actual status. The proportion of the unrelated question $\pi_{x_k}$ is unknown;
thus, estimating \( \pi_{x_h} \) needs another sample of size \( n_{h_2} \)

\( \) such that \( (n_{h_1} + n_{h_2} = n_h) \). The probability of a “Yes” response in the first sample of size \( n_{h_1} \) respondents is assessed below:

\[
\lambda_{M_{h,1}} = (1 + p_{h_1})(p_{h_1}\pi + p_{h_2}\pi_{x_h}) + p_{h_2}^2.
\]  
\[ (47) \]

In the second independent sample of \( n_{h_2} \) respondents, the question is asked only on the unrelated question \( X_h \) to estimate the proportion \( \pi_{x_h} \) of the unrelated character. An unbiased estimator of population proportion \( \hat{\pi}_{M_{1,i},1} \) is given by:

\[
\hat{\pi}_{M_{1,i},1} = \frac{\lambda_{M_{h,1}} - p_{h_2}^2 - p_{h_2}(1 + p_{h_1})\pi_{x_h}}{p_{h_1}(1 + p_{h_1})}.
\]  
\[ (48) \]

The variance of \( \hat{\pi}_{M_{1,i},1} \) is estimated as follows:

\[
\text{Var} \left( \hat{\pi}_{M_{1,i},1} \right) = \sum_{h=1}^{L} W_h \left[ \frac{\lambda_{M_{h,1}} - p_{h_2}^2 - p_{h_2}(1 + p_{h_1})\pi_{x_h}}{p_{h_1}(1 + p_{h_1})} \right]^2.
\]  
\[ (49) \]

The variance of \( \hat{\pi}_{M_{1,i},1} \) is estimated as follows:

\[
\text{Var} \left( \hat{\pi}_{M_{1,i},1} \right) = \sum_{h=1}^{L} \frac{W_h^2}{n_h} V_{M_1},
\]  
\[ (50) \]

case 4.4. A stratified multi-question approach

to estimate the parameters of RRT models, i.e., unrelated innocuous characteristics (\( \pi_x, \pi_y \)), sensitivity level (\( \omega \)), and prevalence of sensitive characteristic (\( \pi \)) in the multi-question approach, each respondent in stratum \( h \) is asked more than two separate questions. In the multi-question approach, DQ method is applied first to estimate the proportion of unrelated innocuous characteristics (\( \pi_{x_h}, \pi_{y_h} \)) used in RRT models and then, apply two RDs, denoted by \( R_{h_1} \) and \( R_{h_2} \), to estimate the proportion of sensitivity level (\( \omega_h \)) and sensitive characteristic (\( \pi_h \)) respectively.

4.4.1. Estimation of sensitivity level under stratification

The question about sensitivity is asked via \( R_{h_1} \) in stratum \( h \). In this randomization process, the sensitive question is “Is the main research question sensitive?” It is asked along with an unrelated innocuous question. We use the device \( R_{h_1} \) suggested by Greenberg et al. [3]. The probability of getting “Yes” response to the \( R_{h_1} \) is:

\[
\lambda_{\omega_h} = \omega_h p_h + (1 - \omega_h)\pi_{y_h}.
\]  
\[ (51) \]

The estimator for \( \omega_h \) is given by:

\[
\hat{\omega}_h = \frac{\lambda_{\omega_h} - (1 - p_h)\pi_{y_h}}{p_h},
\]  
\[ (52) \]

where \( \lambda_{\omega_h} \) is the proportion of “\( y \) Ys” answer reported by \( n \) respondents in the sample \( \lambda_{\omega_h} \sim B(n_h, \lambda_{\omega_h}) \) and \( \hat{\pi}_{y_h} \sim B(n_h, \pi_{y_h}) \). An unbiased estimator for population proportion \( \omega \) is given by:

\[
\hat{\omega}_{(st)} = \sum_{h=1}^{L} W_h \left[ \frac{\lambda_{\omega_h} - (1 - p_h)\hat{\pi}_{y_h}}{p_h} \right].
\]  
\[ (53) \]

It is easy to prove that \( \hat{\omega}_{(st)} \) is unbiased for \( \omega \) with variance:

\[
\text{Var} \left( \hat{\omega}_{(st)} \right) = \sum_{h=1}^{L} W_h^2 \text{Var} \left( \hat{\omega}_h \right),
\]  
\[ (54) \]

where:

\[
\text{Var} \left( \hat{\omega}_h \right) = \frac{1}{p_h^2} \left\{ \frac{\lambda_{\omega_h}(1 - \lambda_{\omega_h})}{n_h} + (1 - p_h)^2 \pi_{y_h}(1 - \pi_{y_h}) \right\}.
\]  
\[ (55) \]
Now, the respondents are given an option to answer the sensitive question directly if they consider question insensitive or provide the response after using device $R_{h_1}$.

4.4.2. Estimation of sensitive attribute
Each respondent in stratum $h$ is given the option to answer the sensitive question directly if they consider the question insensitive or provide the response after using device $R_{h_1}$.

Technique-I optional RRT model under stratification
The probability of getting “Yes” response in stratum $h$ of the proposed binary optional RRT model of Technique-I is:

$$\lambda_{h_1} = (1 - \omega_h)\pi + \omega_h \{ \pi_h p_{h_1} + p_{h_1} (1 - \pi_{x_h}) + p_{h_1} \pi_{x_1} \}.$$  
(60)

Solving Eq. (60) for $\pi_h$, we have an estimator of $\pi_h$ as:

$$\hat{\pi}_{JS_{h_1}} = \hat{\lambda}_{h_1} = \frac{\lambda_{h_1} - \omega_h \{ p_{h_1} - p_{h_2} \} \pi_{x_1}}{1 - \omega_h (1 - p_{h_1})},$$  
(61)

where $\hat{\omega}_h$ is obtained from Eq. (56) and $\hat{\lambda}_{h_1}$ is the proportion of “Yes” answers reported by $n_h$ respondents in the sample, $\hat{\lambda}_{h_1} \sim B(n_h, \lambda_{h_1})$ and $\hat{\pi}_{x_1} \sim B(n_h, \pi_{x_1})$.

After applying the first-order Taylor’s expansion to Eq. (61), we have:

$$\hat{\pi}_{JS_{h_1}} \approx \left[ \frac{\lambda_{h_1} - \omega_h \{ p_{h_1} - p_{h_2} \} \pi_{x_1}}{1 - \omega_h (1 - p_{h_1})} \right] + \frac{\hat{\lambda}_{h_1} - \lambda_{h_1}}{1 - \omega_h (1 - p_{h_1})} + \frac{\omega_h (p_{h_1} - p_{h_2}) (\hat{\pi}_{x_1} - \pi_{x_1})}{1 - \omega_h (1 - p_{h_1})} + \frac{\theta_{h_1} (\hat{\omega}_h - \omega_h)}{1 - \omega_h (1 - p_{h_1})^2}.$$  
(62)

where:

$$\theta_{h_1} = (p_{h_2} - p_{h_3}) \pi_{x_1} + (1 - p_{h_1}) \lambda_{h_1} - p_{h_1}.$$

The stratified estimator $\hat{\pi}_{JS_{1,e}}$ is given by:

$$\hat{\pi}_{JS_{1,e}} = \sum_{h=1}^{L} W_h \hat{\pi}_{JS_{h1}},$$  
(63)

Theorem 4.1. The estimator $\hat{\pi}_{JS_{1,e}}$ is unbiased for $\pi$ with variance, as given by:

$$\text{Var} \left( \hat{\pi}_{JS_{1,e}} \right) = \sum_{h=1}^{L} \frac{W_h^2}{n_h} V_{JS_{h1}},$$  
(64)

where:

$$V_{JS_{h1}} = \lambda_{h_1} (1 - \lambda_{h_1}) + \omega_h^2 (p_{h_1} - p_{h_2})^2 \pi_{x_1} (1 - \pi_{x_1}) \left( \frac{1}{1 - \omega_h (1 - p_{h_1})^2} \right) + \frac{\theta_{h_1}^2 \left( \lambda_{h_1} + \omega_h \{ p_{h_1} - (p_{h_1} - p_{h_2}) \pi_{x_1} \} \right)}{1 - \omega_h (1 - p_{h_1})^4}.$$  
(65)

Proof. Taking expectation on both sides of Eq. (63), we have:

$$E \left( \hat{\pi}_{JS_{1,e}} \right) = \sum_{h=1}^{L} W_h \frac{\lambda_{h_1} - \omega_h \{ p_{h_1} - (p_{h_1} - p_{h_2}) \pi_{x_1} \}}{1 - \omega_h (1 - p_{h_1})},$$  
(66)

Using the fact that $E (\hat{\lambda}_{h_1}) = \lambda_{h_1}$, $E (\hat{\pi}_{x_1}) = \pi_{x_1}$, $E (\hat{\lambda}_{x_1}) = \pi_{x_1}$, and $E (\hat{\pi}_{y_1}) = \pi_{y_1}$, Eq. (66) becomes:

$$E \left( \hat{\pi}_{JS_{1,e}} \right) = \sum_{h=1}^{L} W_h \frac{\lambda_{h_1} - \omega_h \{ p_{h_1} - (p_{h_1} - p_{h_2}) \pi_{x_1} \}}{1 - \omega_h (1 - p_{h_1})} = \pi.$$  
(67)

Thus, $\hat{\pi}_{JS_{1,e}}$ is approximately an unbiased estimator of $\pi$. Now, applying variance on both sides of Eq. (63), we have:

$$V \left( \hat{\pi}_{JS_{1,e}} \right) = \sum_{h=1}^{L} W_h^2 \left[ \frac{\lambda_{h_1} - \omega_h \{ p_{h_1} - (p_{h_1} - p_{h_2}) \pi_{x_1} \}}{1 - \omega_h (1 - p_{h_1})} \right] V \left( \hat{\pi}_{x_1} \right) + \frac{\theta_{h_1}^2 \{ V(\hat{\omega}_h) \}}{1 - \omega_h (1 - p_{h_1})^2}.$$  
(68)

Using the fact that $\text{Var} (\hat{\lambda}_{h_1}) = \lambda_{h_1} (1 - \lambda_{h_1})$ and $\text{Var} (\hat{\pi}_{x_1}) = \pi_{x_1} (1 - \pi_{x_1})$ and substituting the values of $\text{Var} (\hat{\omega}_h)$ given in Eq. (59), we have Eq. (64) which completes the proof.

Technique-II optional RRT model under stratification
The probability of getting “Yes” response in stratum $h$ of the proposed binary optional RRT model of
Technique-II is:
\[ \lambda_{h} = (1 - \omega_{h}) \pi_{h} + \omega \left\{ (1 + p_{h}) (p_{h} \pi_{h} + p_{h} \pi_{h}) + p_{h}^{3} \right\}. \]  
(69)
Solving Eq. (69) for \( \pi_{h} \), we have an estimator of \( \pi_{h} \) as follows:
\[ \hat{\pi}_{JS_{h}} = \frac{\hat{\lambda}_{h} - \hat{\omega}_{h} \left\{ \lambda_{h}^{2} (1 + p_{h}) (1 + p_{h}) \pi_{x_{h}} \right\}}{\left\{ 1 - \hat{\omega}_{h} \left\{ 1 - p_{h} (1 + p_{h}) \right\} \right\}}, \]  
(70)
where \( \hat{\omega}_{h} \) is obtained from Eq. (56) and \( \hat{\lambda}_{h} \) is the proportion of “Yes” answers reported by \( n_{h} \) respondents in the sample, \( \hat{\lambda}_{h} \sim B(n_{h}, \lambda_{h}) \) and \( \hat{\pi}_{x_{h}} \sim B(n_{h}, \pi_{x_{h}}) \). Applying first-order Taylor’s expansion to Eq. (70), we have:
\[ \hat{\pi}_{JS_{h}} \approx \frac{\hat{\lambda}_{h} - \hat{\omega}_{h} \left\{ \lambda_{h}^{2} (1 + p_{h}) (1 + p_{h}) \pi_{x_{h}} \right\}}{\left\{ 1 - \hat{\omega}_{h} \left\{ 1 - p_{h} (1 + p_{h}) \right\} \right\}} + \frac{\theta_{h}}{1 - \hat{\omega}_{h} \left\{ 1 - p_{h} (1 + p_{h}) \pi_{h} \right\}^{2}}, \]  
(71)
where:
\[ \theta_{h} = \lambda_{h} \pi_{h} \left\{ (1 + p_{h}) (p_{h} \pi_{h} + \lambda_{h} p_{h} \pi_{h}) + p_{h}^{3} \right\} \]
The stratified estimator \( \hat{\pi}_{JS_{i \cap t}} \) is obtained as follows:
\[ \hat{\pi}_{JS_{i \cap t}} = \sum_{h=1}^{L} W_{h} \hat{\pi}_{JS_{h}}, \]  
(72)
**Theorem 4.2.** The estimator \( \hat{\pi}_{JS_{i \cap t}} \) is unbiased for \( \pi \) with variance as given by:
\[ \text{Var} \left( \hat{\pi}_{JS_{i \cap t}} \right) = \sum_{h=1}^{L} W_{h}^{2} / n_{h} V_{JS_{h}}, \]  
(73)
where:
\[ V_{JS_{h}} = \frac{\lambda_{h} \left\{ (1 - \lambda_{h}) + \omega^{2} (p_{h} \pi_{h} (1 + p_{h})^{2} \pi_{x_{h}} (1 - \pi_{x_{h}}) \right\}}{\left\{ 1 - \omega_{h} \left\{ 1 - p_{h} (1 + p_{h}) \right\} \right\}^{2}} + \frac{\theta_{h}^{2} \left\{ \lambda_{h} \pi_{h} (1 - \lambda_{h}) + (1 - p_{h})^{2} \pi_{y_{h}} (1 - \pi_{y_{h}}) \right\}}{\left\{ 1 - \omega_{h} \left\{ 1 - p_{h} (1 + p_{h}) \right\} \right\}^{2}}. \]  
(74)
**Proof.** The proof is analogous to that of Theorem 4.1.

Technique-III optional RRT model under stratification
The probability of getting “Yes” response in stratum \( h \) of the proposed binary optional RRT model of Technique-III is:
\[ \lambda_{h} = (1 - \omega_{h}) \pi_{h} + \omega \left\{ (1 + p_{h}) (p_{h} \pi_{h} + p_{h} \pi_{h} + p_{h}^{3} \pi_{x_{h}}) + p_{h}^{3} \right\}. \]  
(75)
Solving Eq. (75) for \( \pi_{h} \), we have an estimator for \( \pi_{h} \) as follows:
\[ \hat{\pi}_{JS_{h}} = \frac{\hat{\lambda}_{h} - \hat{\omega}_{h} \left\{ \lambda_{h}^{2} \pi_{h} (1 + p_{h}) (1 - \pi_{h} + p_{h} \pi_{h}) \right\}}{\left\{ 1 - \hat{\omega}_{h} \left\{ 1 - p_{h} (1 + p_{h}) \right\} \right\}}, \]  
(76)
where \( \hat{\omega}_{h} \) is obtained from Eq. (56) and \( \hat{\lambda}_{h} \) is the proportion of “Yes” answers reported by \( n_{h} \) respondents in the sample, \( \hat{\lambda}_{h} \sim B(n_{h}, \lambda_{h}) \) and \( \hat{\pi}_{x_{h}} \sim B(n_{h}, \pi_{x_{h}}) \). Applying first-order Taylor’s expansion to Eq. (76), we have:
\[ \hat{\pi}_{JS_{h}} \approx \frac{\lambda_{h} - \omega \left\{ (1 + p_{h}) \pi_{h} (1 - \pi_{h} + p_{h} \pi_{h}) \right\}}{\left\{ 1 - \omega_{h} \left\{ 1 - p_{h} (1 + p_{h}) \right\} \right\}} \]
\[ + \frac{\hat{\lambda}_{h} - \hat{\lambda}_{h}}{\left\{ 1 - \hat{\omega}_{h} \left\{ 1 - p_{h} (1 + p_{h}) \right\} \right\}^{2}} \]
\[ - \frac{\omega \hat{p}_{h} \pi_{h} (1 + p_{h}) \pi_{x_{h}} (1 - \pi_{x_{h}})}{\left\{ 1 - \hat{\omega}_{h} \left\{ 1 - p_{h} (1 + p_{h}) \right\} \right\}^{2}} \]
\[ + \frac{\theta_{h} \omega \pi_{h} (1 - \pi_{h} + p_{h} \pi_{h})}{\left\{ 1 - \hat{\omega}_{h} \left\{ 1 - p_{h} (1 + p_{h}) \right\} \right\}^{2}}, \]  
(77)
where:
\[ \theta_{h} = \lambda_{h} \pi_{h} (1 - p_{h} + p_{h} \pi_{h}) - \pi_{x_{h}} p_{h} \pi_{h} - p_{h}. \]
The stratified estimator \( \hat{\pi}_{JS_{i \cap t}} \) is given by:
\[ \hat{\pi}_{JS_{i \cap t}} = \sum_{h=1}^{L} W_{h} \hat{\pi}_{JS_{h}}. \]  
(78)
Thus, we have the following theorem and its proof is similar to that of Theorem 4.1.

**Theorem 4.3.** The estimator \( \hat{\pi}_{JS_{i \cap t}} \) is unbiased for \( \pi \) with variance, as given by:
\[ \text{Var} \left( \hat{\pi}_{JS_{i \cap t}} \right) = \sum_{h=1}^{L} \frac{W_{h}^{2}}{n_{h}} V_{JS_{h}}, \]  
(79)
where:
\[ V_{JS_{h}} = \frac{\lambda_{h} \left\{ (1 - \lambda_{h}) + \omega^{2} \hat{p}_{h} \pi_{x_{h}} (1 - \pi_{x_{h}}) \right\}}{\left\{ 1 - \omega_{h} \left\{ 1 - p_{h} (1 + p_{h}) \right\} \right\}^{2}} \]
\[ + \frac{\theta_{h}^{2} \left\{ \lambda_{h} \pi_{h} (1 - \lambda_{h}) + (1 - p_{h})^{2} \pi_{y_{h}} (1 - \pi_{y_{h}}) \right\}}{\left\{ 1 - \omega_{h} \left\{ 1 - p_{h} (1 + p_{h}) \right\} \right\}^{2}} \]  
(80)
**Corollary 4.1.** In proportional allocation, the size of each stratum is \( n_{h} = n \frac{W_{h}}{n_{h}} \) and the variances of \( \hat{\pi}_{JS_{i \cap t}} \) and \( \hat{\pi}_{M_{i \cap t}} \) are respectively given below:
\[ \text{Var} \left( \hat{\pi}_{JS_{i \cap t}} \right) = \frac{1}{n} \sum_{h=1}^{L} W_{h} V_{JS_{h}}, \]  
(81)
and:
\[
\text{Var} \left( \hat{\pi}_{M_{i,t}} \right) = \frac{1}{n} \sum_{k=1}^{K} W_k V_{M_k}, \quad (82)
\]
for \( i = 1, 2, 3, \ldots \)

### 4.5. Relative efficiency

The Relative Efficiency (RE) of the proposed optimal RRT models with respect to the RRT models of Mahmood et al. [6] under stratification by proportional allocation method is defined as:

\[
RE(i) = \frac{\text{Var} \left( \hat{\pi}_{M_{i,t}} \right)}{\text{Var} \left( \hat{\pi}_{J_{S_i,t}} \right)}, \quad i = 1, 2, 3. \quad (83)
\]

To calculate it empirically, we have chosen \( n = 100 \) with two strata having stratum weights \( W_1 = 0.3 \), \( W_2 = 0.7 \) and \( (W_1 = 0.7, W_2 = 0.3) \) for different values of \( \pi_1 \) and \( \pi_2 \). The design parameters are defined as \( p_1 = p_1, p_2 = p_2, \) \( \rho_1 = \rho_1, \rho_2 = \rho_2, \) \( \omega = \omega_1 = \omega_2, \) \( \pi_y = \pi_y_1, \pi_x = \pi_x_1, \) and \( p = p_1 = p_2, \) respectively. The results of each model with respect to their competitor models are discussed as follows:

(i) Table 4 shows that \( RE(1) > 1 \) decreases when \( p_1 \) and \( \omega \) values increase from 0.2 to 0.8 and from 0.1 to 0.9 by increment of 0.2, respectively.

| \( p_1 \) | \( \pi_1 \) | \( \pi_2 \) | \( W_1 \) | \( W_2 \) | \( \pi_y = 0.35 \) | \( \pi_y = 0.65 \) |
|---|---|---|---|---|---|---|
| \( 0.08 \) | 0.13 | 0.3 | 0.7 | 18.71 | 9.15 | 4.80 | 2.40 | 0.98 | 17.17 | 8.86 | 4.90 | 2.46 | 1.03 |

| \( 0.88 \) | 0.93 | 0.3 | 0.7 | 1.79 | 1.50 | 1.28 | 1.09 | 0.93 | 1.78 | 1.50 | 1.28 | 1.09 | 0.93 |
Table 5. Relative efficiency of the proposed Technique-II optional RRT over Technique-II RRT when \( n = 1000, \pi_\omega = 0.85, p = 0.7 \) and at various choices of \( \omega, p_1, p_3 = 2(1-p_1)/3 \) and \( p_2 = (1-p_1-p_3) \).

| \( p_1 \) | \( \pi_1 \) | \( \pi_2 \) | \( W_1 \) | \( W_2 \) | \( \pi_y = 0.35 \) | \( \omega \) | \( 0.1 \) | \( 0.3 \) | \( 0.5 \) | \( 0.9 \) | \( \pi_y = 0.65 \) | \( \omega \) | \( 0.1 \) | \( 0.3 \) | \( 0.5 \) | \( 0.7 \) | \( 0.9 \) |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 0.08 | 0.13 | 0.3 | 0.7 | 30.92 | 15.04 | 8.39 | 4.74 | 2.45 | 28.05 | 14.54 | 8.39 | 4.86 | 2.57 |
| 0.28 | 0.33 | 0.3 | 0.7 | 23.47 | 14.35 | 8.66 | 4.89 | 2.35 | 22.45 | 14.07 | 8.66 | 4.99 | 2.46 |
| 0.48 | 0.53 | 0.3 | 0.7 | 21.72 | 14.60 | 9.07 | 4.98 | 2.20 | 21.31 | 14.45 | 9.07 | 5.06 | 2.30 |
| 0.68 | 0.73 | 0.3 | 0.7 | 24.48 | 16.21 | 9.68 | 4.99 | 2.00 | 23.74 | 16.15 | 9.68 | 5.04 | 2.08 |
| 0.88 | 0.93 | 0.3 | 0.7 | 43.83 | 21.59 | 10.70 | 4.84 | 1.73 | 43.81 | 21.59 | 10.70 | 4.87 | 1.80 |

So, we conclude that the efficiency of Technique-I optional RRT model may either increase or decrease in the case of different combinations of design parameters;

(ii) According to Table 5, when the value of \( p_1 \) increases from 0.2 to 0.8, \( RE(2) > 1 \) decreases. Similarly, an attenuating pattern is observed at fixed values of \( p_1, \pi_1, \) and \( \pi_2 \) when \( \omega \) values increase from 0.1 to 0.9. Overall, result shows that Technique-II optional RRT model is more efficient than the competitor Technique-II of Mahmood et al. [5];

(iii) In Table 6, we observe that the proposed Technique-III optional RRT model is more effi-
Table 6. Relative efficiency of the proposed Technique-III optional RRT over Technique-III RRT when $n = 1000$, $\pi_x = 0.85$, $p = 0.7$ and at various choices of $\omega$, $p_1$, $p_2 = (1 - p_1)/3$, and $p_3 = (1 - p_1 - p_2)$.

6. Concluding remarks

According to the numerical comparison, the proposed optional Randomized Response Technique (RRT) models estimated by using the multi-question approach were more efficient than the corresponding Techniques of Mahmod et al. [5]. It was demonstrated that for a higher sensitive question, the proposed optional RRT model and the competitor models provided equal protection for the respondents. Moreover, the proposed optional RRT models simultaneously estimated the prevalence of sensitive attribute and sensitivity
level, compared to competitor RRT models. We, therefore, preferred the proposed optional RRT models over competitor models. An extensive simulation study showed that the empirical mean and variance of $\hat{\tau}_{RRT}(i = 1, 2, 3)$ and $\hat{\sigma}$ were in good agreement with the corresponding theoretical values. It was also shown that $\hat{\tau}_{RRT}$ in first-order approximation worked very well. The superiority of the suggested optional RRT under stratification was revealed through a numerical comparison and it was observed that the proposed optional RRT models under stratified random sampling outperformed stratified techniques of Malmood et al. [3]. Moreover, we also observed that design parameters played an important role in increasing or decreasing the efficiency of the suggested optional RRT models.

Acknowledgments

The authors are thankful to the editor and anonymous learned referees for their valuable suggestions which improved the quality of this work.

Biographies

Ghulam Narjis completed her PhD degree in Statistics from Quaid-i-Azam University Islamabad, Pakistan in November 2019. She has published five article papers in internationally reputed journals in the field of survey methodologies, randomized response, and data analysis. Her areas of interest include sampling theory and Bayesian analysis. The current article is a part of her PhD research.

Javid Shabbir is working as a Tenured Professor of Statistics at Department of Statistics Quaid-I-Azam University Islamabad, Pakistan. He has completed his PhD in Statistics from Kent University at Canterbury, UK in 1997. He availed Post-Doctoral positions at University of Southern Maine 2003, USA in 2003 and University of North Carolina at Greensboro USA in 2005. He has published about 300 articles in different internationally reputed journals. His area of research includes survey sampling and randomized response techniques. He has supervised many MPhil and PhD students at the department.
