The Frequency of ABO Blood Group among Male Inmates in a Typical Nigerian Prison

Minari JB* and Mgbada NM
Department of Cell Biology and Genetics, University of Lagos, Nigeria

Abstract
The frequency of ABO blood group was carried out among male inmates in a typical Nigerian prison. This study sought to correlate blood grouping with crime to determine whether a relationship could be established. The results obtained will serve as a platform for instigating awareness to relevant authorities and the public at large. The experiment was carried out at the hospital premises of the Kirikiri medium prison Apapa Lagos Nigeria. A total of 501 male inmates voluntarily provided themselves for this study. Blood was taken by piercing the thumb with a lancet and dropped on the card. The ABO and rhesus blood grouping was determined using felines card method with commercially prepared antisera. The frequency of each blood type was calculated. Among the male inmates charged for various crimes, blood group O+ has the most occurrences, having the highest blood group frequency for stealing, fighting, robbery and rape. Blood group A+ followed, having the highest frequency for inmates charged for fraud and murder. Blood group B+ has the least occurrence, having similar frequency with blood group A for inmates charged for Murder. This study indicates that Blood group O+ had the highest frequency for inmates convicted for the various crimes. Blood type AB+ and AB- had the least frequency. The results obtained were compared with previously published data. Some variations in frequencies were observed. The frequency of ABO and Rhesus blood groups appeared to be stable and consistent with reports from previous studies in Nigeria.

Materials and Method

Materials used
Materials used include: Anti sera A, B and D, Cotton wool, Alcohol swab, Blood group test card X 1 (inside foil pouch), Blood group result card, Lancets X 2, Glass rod, Applicators (eldonsticks) and Disposable container.

Blood group and RH determination: The ABO and rhesus blood grouping was determined using felines card method. (2005) Drops of antigens for A, B, AB and O blood groups were placed separately using, pipette, on a tile with one row of four columns each marked A, B, AB and O respectively. A drop of the subject's blood was placed on the anti sera on each column. The mixture was examined for agglutination. Agglutination in a particular mixture indicated the ABO blood group. When there was no agglutination in the anti A and B mixture, the sample was O. In the case of Rh positive, a drop of 0.5 ml of the subject's blood was dropped on another card, Lancets X 2, Glass rod, Applicators (eldonsticks) and Disposable container. The ABO and rhesus blood grouping was determined using felines card method. (2005) Drops of antigens for A, B, AB and O blood groups were placed separately using, pipette, on a tile with one row of four columns each marked A, B, AB and O respectively. A drop of the subject's blood was placed on the anti sera on each column. The mixture was examined for agglutination. Agglutination in a particular mixture indicated the ABO blood group. When there was no agglutination in the anti A and B mixture, the sample was O. In the case of Rh positive, a drop of 0.5 ml of the subject's blood was dropped on another card.

Clearance
This study was approved by the Lagos state Comptroller of Prisons through the Deputy Comptroller of Prisons Kirikiri Apapa Lagos.

Keywords: Blood group, Male inmates, Nigerian, Prison

Introduction
Blood is a bodily fluid in animals that delivers necessary substances such as nutrients and oxygen to the cells and transports metabolic waste products away from those same cells. In vertebrates, it is composed of blood cells suspended in blood plasma. Plasma, which constitutes 55% of blood fluid, is mostly water (92% by volume), and contains dissipated proteins, glucose, mineral ions, hormones, carbon dioxide (plasma being the main medium for excretory product transportation), and blood cells [1]. Blood can be classified into different groups based on the presence or absence of inherited antigenic substances on the surface of red blood cells (RBCs). Blood types are inherited and represent contributions from both parents. Forensics use a system called the 'ABO System', which is a system that measures antigens; antigens within the body determine blood type and are normally categorised as either A or B. Also within the blood typing system there are Rhesus antigens, which can be categorised as Type D; should an individual's red blood cells have these Rhesus antigens, they are classified as Rh Positive and likewise if they do not appear they are classified as Rh negative [2].

At a crime scene where there has been blood spilled - either that of the victim or that of the assailant - and indeed in some instances that of both parties; a serologist will take blood samples in order to identify who’s blood belongs to whom. Blood and other body fluid collected from victim and also from criminal has important role in the identification and investigation of criminal cases. Forensics uses Blood samples for the identification of criminals. Though information is lacking in this area of research, the need therefore arises to find the relationship between blood group and crime. If we have availability of this information beforehand it will aid criminal investigations especially in the identification of individuals there by solving the challenges in identifying these criminals. This study therefore sought to correlate blood grouping with crime to determine whether a relationship could be established.

A+ was the most predominant group, occurring with 29% followed by blood group O+ occurring in 20%. The result also shows Blood group AB+ as the least compared to Blood group A+ and B+. The corresponding rhesus negative of the blood group shows blood group A- and AB- being the least compared to blood group B- and O-.

For inmates who were imprisoned for stealing as seen in Figure 2, blood group O+ was the most prominent group, occurring with 35% followed by blood group B+ occurring in 25% then blood group A+ with 22%. Blood group AB+ was occurring least in the sample population with 6%.

As shown in Figure 3, the frequency distributions of ABO blood group for inmates charged for robbery were all consistent. The most prominent blood group was Blood group O+ which occurred with 44%, followed by blood group A+ (24%) with AB+ having the least percentage for Rhesus positive blood groups (0%). It was also observed that blood group AB- was the least with 0% when compared to A, B, O rhesus negative blood groups.

Blood group O+ was higher with 37% for inmates imprisoned for fighting when compared with other blood groups as seen in Figure 4. Blood group A+, B+, and AB+ gave the following result respectively, 32%, 16% and 5%.

Figure 5 shows the frequency distribution of ABO blood group for inmates imprisoned for murder. Blood groups A+ and B+ (26%) were the most prominent group followed by blood group O+ (25%). Among rape inmates, Figure 6 shows that blood group O+ was the most predominant occurring in 39%. Blood group A+ and B+ occurred with (24%) among the inmates while blood group AB has the least percentage with 4%.

Nigeria. Informed consent was obtained from all the participants used in this experiment.

Limitation

Some of the limitations encountered during the course of the study are due to the fact that: some of the inmates are illiterate and only understood their native languages, so it was difficult to communicate with them because of language barrier. Secondly, Religious Belief and Trust and thirdly, Fear of unknown. All these factors pose as a barrier which made some of them to be reluctant in participating in the experiment.

Results

The frequency of ABO Blood group for male inmates in Kirikiri medium prison, charged for fraud were shown (Figure 1). Blood group
Discussion

Over the past three-quarters of a century, information from studies on blood groups has been applied to medico-legal application. The use of blood group substances in medico-legal examination is based on the fact that once a blood group is established in an individual; it remains unchanged throughout his life [3]. Though there are limited studies relating blood group to crime but lots of research has been carried out on blood group frequency among different populations. There are also myths correlating blood group and personality among the Asians. The desire to know about blood type, started because of an assertion from the West, which stated that Asians were lower, in the evolutionary chain and that they were more closely related, to animals than other races. Interestingly, that was the start point where Asian countries became deep into the study of blood type. They opined that personality can influence one’s behaviour. However there is no scientific evidence to back this up [4].

The result of this research shows that blood group A+ (29%) is the most prominent for male inmates charged with fraud or obtained by trick (OBT). The result is also in agreement to the Japanese myth that most prominent for male inmates charged with fraud or Obtained by trick (OBT). The result is also in agreement to the Japanese myth that most prominent for male inmates charged with fraud or Obtained by trick (OBT). The result is also in agreement to the Japanese myth that most prominent for male inmates charged with fraud or Obtained by trick (OBT). The result is also in agreement to the Japanese myth that most prominent for male inmates charged with fraud or Obtained by trick (OBT). The result is also in agreement to the Japanese myth that most prominent for male inmates charged with fraud or Obtained by trick (OBT). The result is also in agreement to the Japanese myth that most prominent for male inmates charged with fraud or Obtained by trick (OBT). The result is also in agreement to the Japanese myth that most prominent for male inmates charged with fraud or Obtained by trick (OBT).

This study also revealed that Blood group O+ has the most occurrence among male inmates charged for stealing and robbery (35%), followed by A (28.77%) then B (22.64%) and AB (4.25%). This result might be as a result of the high prevalence of blood group O and A among males in Nigeria. This result is in agreement with the result obtained by Bassey and Imabong 2006 [10]. His study showed O factor had the greatest number of individuals (44.34%), followed by A (28.77%) then B (22.64%) and AB (4.25%) For those imprisoned for rape blood group A and B has the same value (24%). Roshi2009 also observed similar personality trait. He inferred that individuals with type O blood are Arrogant, vain, insensitive and ruthless. Blood group AB+ has a lower frequency when compared to the other blood groups. Personalities studies has also revealed that AB’s blood group are known to be cool, controlled, rational, introverted and empathic as observed by Kathy 2007 [4].

Conclusion

This study revealed that blood group O+ has the most occurrence for male inmates charged for various crimes. O+ blood type has the highest blood group frequency for stealing, fighting, robbery and rape. Blood group A+ followed, having the highest frequency for inmates charged for fraud and murder. Blood group B has the least occurrence, having similar frequency with blood group A for inmates charged for Murder. Blood type A has the least occurrence having highest blood group frequency for only drug abuse. This study revealed that Blood group O was most frequent among the ABO blood groups occurring with highest frequency in most of the crimes recorded in this study. Thus this result shows that blood type O might predispose individuals to the crimes observed in this study.
