Weierstrass sets on finite graphs

Alessio Borzì

December 22, 2021

Abstract

We study two possible tropical analogues of Weierstrass semigroups on graphs, called rank and functional Weierstrass sets. We prove that on simple graphs, the first is contained in the second. We completely characterize the subsets of $\mathbb{N}$ arising as a functional Weierstrass set of some graph. Finally, we give a sufficient condition for a subset of $\mathbb{N}$ to be the rank Weierstrass set of some graph, allowing us to construct examples of rank Weierstrass sets that are not semigroups.

1 Introduction

Let $X$ be a smooth projective algebraic curve of genus $g$ and fix a point $P \in X$. Denote by $H(P)$ the set of pole orders at $P$ of rational functions regular on $X \setminus \{P\}$. By the Weierstrass gap theorem (see [11, III.5.3]), the set of gaps $G(P) = \mathbb{N} \setminus H(P)$ has cardinality exactly $g$. This implies that $H(P)$ is a numerical semigroup, that is, a cofinite additive submonoid of $\mathbb{N}$. The numerical semigroups arising in this way are called Weierstrass semigroups. We have $G(P) = \{1, \ldots, g\}$ except in a finite number of points, called Weierstrass points of $X$ (see [11 III.5.9]).

In 1893 Hurwitz [13] asks if all the numerical semigroups arise in this manner. Several years later, in 1980, Buchweitz [5] showed that the numerical semigroup $S = \langle 13, 14, 15, 16, 17, 18, 20, 22, 23 \rangle$ is not Weierstrass (see also [9 page 499]). The proof essentially gives the following necessary condition for a semigroup to be Weierstrass: the $m$-sumset of the set of gaps must satisfy $|mG(P)| \leq (2m - 1)(g - 1)$ for any integer $m \geq 2$. Several numerical semigroups not satisfying the previous condition are constructed in [16].
Furthermore, in [10] it was proved that for a fixed numerical semigroup $S$, the set of integers $m$ that do not satisfy the above condition is finite. Despite these results, little is known more generally about the family of Weierstrass semigroups. For instance, the problem of determining its density in the set of all numerical semigroups is still open [15].

After the advent of tropical geometry, the tropical analogues of many classical results in algebraic geometry were found. Baker and Norine [2] proved a Riemann-Roch theorem for graphs, which was successively extended by Gathmann and Kerber [12] and Mikhalkin and Zharkov [17] to metric graphs, namely (abstract) tropical curves. The analogue notion of Weierstrass points on graphs was studied for instance in [1, Section 4] and [19].

Inspired by a work of Kang, Matthews and Peachey [14], in this paper we investigate possible tropical analogues of Weierstrass semigroups. We will focus our attention on graphs rather than metric graphs, the latter are left for future work. It was already noted in [14] that two possible non-equivalent definitions can be given, as we now explain. Throughout this paper, a graph will mean a finite connected multigraph having no loop edges. Let $G$ be a graph and fix a vertex $P \in V(G)$ of $G$. The functional Weierstrass set of $G$ at $P$ is defined by

$$H_f(P) = \{ n \in \mathbb{N} : \exists f \in \mathcal{M}(G) \text{ that has a unique pole of order } n \text{ at } P \},$$

where $\mathcal{M}(G)$ is the set of all integer-valued functions on the vertices of $G$. The rank Weierstrass set of $G$ at $P$ is defined by

$$H_r(P) = \{ n \in \mathbb{N} : r(nP) > r((n-1)P) \},$$

where $r(D)$ denotes the rank of the divisor $D$ of the graph $G$, in the sense of Baker and Norine [2] (see Section 2). Classically, for curves, we have $H_f(P) = H_r(P) = H(P)$. However this is not the case for graphs, for instance the cardinality of the set difference $H_f(P) \setminus H_r(P)$ can be arbitrarily large [14, Proposition 3.9].

Our first main result was conjectured in [14], and relates the two sets when $G$ is a graph with no multiple edges and more than one vertex, that in this paper will be called simple.

**Theorem A** (Theorem 3.4). Let $G$ be a simple graph. For every $P \in V(G)$ we have $H_r(P) \subseteq H_f(P)$. 

---

2
As an application of the previous theorem, we calculate the rank and functional Weierstrass set of the graphs \( K_{n+1} \) and \( K_{n,m} \).

Secondly, we completely characterize the subsets of \( \mathbb{N} \) arising as functional Weierstrass sets of graphs and of simple graphs, answering a question in [14].

**Theorem B** (Theorem 4.5). The functional Weierstrass sets of graphs (resp. simple graphs) are precisely the additive submonoids of \( \mathbb{N} \) (resp. numerical semigroups).

Further, we give a sufficient condition for a subset of \( \mathbb{N} \) to be the rank Weierstrass set of a graph.

**Theorem C** (Theorem 5.3). Let \( e_1 \geq e_2 \geq \cdots \geq e_n \geq 0 \) be integers and set \( s_i = \sum_{j=1}^{i} e_j \). There exists a simple graph \( G \) with a vertex \( P \in V(G) \) such that

\[
H_r(P) = \{0, s_1, s_2, \ldots, s_{n-1}\} \cup (s_n + \mathbb{N}).
\]

The previous theorem allows us to construct families of graphs in which the rank Weierstrass set is not a semigroup (see Example 5.6), justifying the name “Weierstrass set”.

## 2 Preliminaries

In this section, we fix our notation and review the basics and some results of Riemann-Roch theory on finite graphs.

In this paper, a graph will mean a finite connected multigraph having no loop edges; a simple graph will mean a graph with no multiple edges and more than one vertex. Let \( G \) be a graph and let \( V(G) \) (resp. \( E(G) \)) denote the set of vertices (resp. edges) of \( G \). The set \( \text{Div}(G) \) of divisors of \( G \) is the free abelian group on \( V(G) \). We think of a divisor as a formal integer linear combination of the vertices \( D = \sum_{P \in V(G)} a_P P \in \text{Div}(G) \) with \( a_P \in \mathbb{Z} \). For convenience, we will write \( D(P) \) for the coefficient \( a_P \) of \( P \) in \( D \). The degree of a divisor \( D \) is defined by \( \deg(D) = \sum_{P \in V(G)} D(P) \in \mathbb{Z} \). If \( D, D' \in \text{Div}(G) \) are two divisors, then \( D \geq D' \) if and only if \( D(P) \geq D'(P) \) for all \( P \in V(G) \). A divisor \( D \) is effective if \( D \geq 0 \). The set of effective divisors of degree \( d \) is denoted by \( \text{Div}^d_+(G) \).

Let \( \mathcal{M}(G) = \text{Hom}(V(G), \mathbb{Z}) \) be the set of integer-valued functions on the vertices of \( G \). For every vertex \( P \in V(G) \), define the indicator function
Let $f \in \mathcal{M}(G)$, and denote by $\mathcal{N}(P)$ the neighbourhood of $P \in V(G)$, that is, the subset of vertices of $G$ adjacent to $P$. Define the Laplacian operator $\Delta : \mathcal{M}(G) \to \text{Div}(G)$ by

$$
\Delta f = \sum_{P \in V(G)} \left( \sum_{Q \in \mathcal{N}(P)} (f(P) - f(Q)) \right) P.
$$

The divisors of the form $\Delta f$ are principal. For convenience we will write $\Delta_P f$ for the coefficient $\Delta f(P)$. If we think of $f$ as a vector, the Laplacian operator can be seen as the multiplication of the Laplacian matrix $Q = D - A$, where $D$ is the diagonal matrix of the degrees of the vertices, and $A$ is the adjacency matrix of $G$. The matrix $Q$ has rank $|V(G)| - 1$, and $\ker Q = (1, \ldots, 1)^t$. From this fact, it is easy to see that every principal divisor has degree 0.

Two divisors $D, D' \in \text{Div}(G)$ are linearly equivalent, written $D \sim D'$, if $D - D' = \Delta f$, for some $f \in \mathcal{M}(G)$. The linear system associated to a divisor $D \in \text{Div}(G)$ is

$$|D| = \{ E \in \text{Div}(G) : E \sim D, E \geq 0 \}.$$

The rank $r(D)$ of a divisor $D$ is defined as $-1$ if $|D| = \emptyset$, otherwise

$$r(D) = \max \{ k \in \mathbb{N} : |D - E| \neq \emptyset, \forall E \in \text{Div}_k(G) \}.$$

Lemma 2.1. \cite{BakerNorine2006} For all $D_1, D_2 \in \text{Div}(G)$ with $r(D_1), r(D_2) \geq 0$ we have $r(D_1 + D_2) \geq r(D_1) + r(D_2)$.

Lemma 2.2. \cite{BakerNorine2013} Let $G$ be a graph, and let $D \in \text{Div}(G)$. Then $r(D - P) \geq r(D) - 1$ for all $P \in V(G)$, and if $r(D) \geq 0$, then $r(D - P) = r(D) - 1$ for some $P \in V(G)$.

The canonical divisor of $G$ is

$$K_G = \sum_{P \in V(G)} (\deg(P) - 2)P.$$

It has degree $\deg(K_G) = 2g - 2$, where $g = |E(G)| - |V(G)| + 1$ is the genus (or cyclomatic number) of the graph $G$. We are now ready to state the Riemann-Roch theorem for graphs, proved by Baker and Norine \cite{BakerNorine2006}.
Theorem 2.3 (Riemann-Roch for graphs). Let $D$ be a divisor on a graph $G$ of genus $g$. Then

$$r(D) - r(K_G - D) = \deg(D) + 1 - g.$$

For $A \subseteq V(G)$ and $Q \in A$, let $\text{outdeg}_A(Q)$ denote the number of edges incident with $Q$ and a vertex in $V(G) \setminus A$. Fix $P \in V(G)$. A divisor $D$ is $P$-reduced if it is effective in $V(G) \setminus \{P\}$, and every non-empty subset $A \subseteq V(G) \setminus \{P\}$ contains a vertex $Q \in A$ such that $\text{outdeg}_A(Q) > D(Q)$.

Proposition 2.4. [2, Proposition 3.1] Let $P$ be a vertex of a graph $G$. For every divisor $D$ in $G$, there exists a unique $P$-reduced divisor $D'$ such that $D \sim D'$.

Following [1, Section 4], a vertex $P \in V(G)$ of a graph $G$ of genus $g$, is a Weierstrass point if $r(gP) \geq 1$. We now state an analogue of the Weierstrass gap theorem for graphs.

Lemma 2.5. [3, Lemma 4.2] Let $G$ be a graph of genus $g$, and fix a vertex $P \in V(G)$.

1. $P$ is a Weierstrass point if and only if $\mathbb{N} \setminus H_r(P) \neq \{1, \ldots, g\}$.
2. $|\mathbb{N} \setminus H_r(P)| = g$.
3. $\mathbb{N} \setminus H_r(P) \subseteq \{1, 2, \ldots, 2g - 1\}$.

Note that, in the classical case for curves, the inclusion $\mathbb{N} \setminus H(P) \subseteq \{1, \ldots, 2g - 1\}$ follows from $|\mathbb{N} \setminus H(P)| = g$ and the fact that $H(P)$ is a semigroup (see [20, Lemma 2.14]).

We now describe a binary operation on graphs that we will use frequently in Section 4 and 5. Let $G_1$ and $G_2$ be two graphs and $v_1$ and $v_2$ be vertices of respectively $G_1$ and $G_2$. The vertex gluing (or vertex identification) of $v_1$ and $v_2$ is the graph $G$ obtained from $G_1$ and $G_2$ by identifying $v_1$ and $v_2$ as a new vertex $v$. 

![Vertex Gluing Diagram]
3 The inclusion $H_r(P) \subseteq H_f(P)$

In this section, we will assume that $G$ is a simple graph. We will prove the inclusion $H_r(P) \subseteq H_f(P)$ for every vertex $P \in V(G)$. First, we will need a series of lemmas, inspired by the Cori-Le Borgne algorithm \cite{7, Proposition 2} for the rank of divisors of a complete graph.

Lemma 3.1. Fix a vertex $P \in V(G)$ and let $D$ be a $P$-reduced divisor on $G$. There exists a neighbour $Q \in V(G) \setminus \{P\}$ of $P$ such that $D(Q) = 0$.

Proof. Set $A = V(G) \setminus \{P\}$ and let $\mathcal{N}(P) \subseteq A$ be the set of neighbours of $P$. Assume by contradiction that $D(Q) \geq 1$ for all $Q \in \mathcal{N}(P)$. Since $G$ is simple, we have outdeg$_A(Q) = 1$ for all $Q \in \mathcal{N}(P)$. This implies $D(Q) \geq$ outdeg$_A(Q)$ for all $Q \in A$, contradicting the fact that $D$ is $P$-reduced.

Let $D$ be a divisor on $G$ of rank $r$. Using the same terminology as in \cite{7, 8}, a proof for the rank of $D$ is an effective divisor $E$ of degree $r + 1$ with $|D - E| = \emptyset$. We denote by Proof$(D)$ the set of proofs of $D$. Note that if $D \sim D'$, then Proof$(D) = $ Proof$(D')$.

Lemma 3.2. Fix a vertex $P \in V(G)$ and let $D$ be a $P$-reduced divisor on $G$ of rank zero. We have Proof$(D) \setminus \{P\} \neq \emptyset$.

Proof. If $D(P) > 0$, then $P \notin$ Proof$(D) \neq \emptyset$. Now assume $D(P) = 0$, from Lemma \cite[3.1]{3} there exists a neighbour $Q$ of $P$ such that $D(Q) = 0$. The divisor $D' = D - Q$ is $Q$-reduced. In fact, let $A \subseteq V(G) \setminus \{Q\}$: if $P \notin A$ then, since $D$ is $P$-reduced, we have outdeg$_A(v) > D(v) = D'(v)$ for some $v \in A$; otherwise if $P \in A$, then outdeg$_A(P) \geq 1 > 0 = D(P) = D'(P)$. Finally, since $D'(Q) < 0$ and $D'$ is $Q$-reduced, it follows that $Q$ is a proof for $D$ with $Q \neq P$.

Lemma 3.3. Let $D$ be a divisor on $G$. For every vertex $P \in V(G)$ there exists $E \in$ Proof$(D)$ such that $E(P) = 0$.

Proof. Without loss of generality, we can assume that $D$ is $P$-reduced. We proceed by induction on the rank $r$ of $D$. The case $r = -1$ is trivial. If $r = 0$ the assertion follows from Lemma \cite[3.2]{3}.

Now suppose that $D$ has rank $r \geq 1$ and assume the statement for divisors of rank $r - 1$. From Lemma \cite[2.2]{2} we have $r(D - P') = r - 1$ for some vertex $P' \in V(G)$. By the inductive hypothesis there exists $E' \in$ Proof$(D - P')$ such
that \( E'(P) = 0 \). Now apply Lemma 3.2 to the \( P \)-reduced divisor equivalent to \( D - E' \). Thus there exists \( Q \in \text{Proof}(D - E') \) with \( Q \neq P \). We conclude by noting that \( E = E' + Q \in \text{Proof}(D) \) and \( E(P) = 0 \).

Now we prove the main result of the section. We will follow the proof outlined in [14, Theorem 2.4] in which the previous Lemma 3.3 was the key step missing.

**Theorem 3.4.** Let \( G \) be a simple graph. For every \( P \in V(G) \) we have \( H_r(P) \subseteq H_f(P) \).

**Proof.** Let \( n \in H_r(P) \). By Lemma 3.3, there exists an effective divisor \( E \in \text{Proof}((n - 1)P) \) such that \( E(P) = 0 \). By the choice of \( E \) and since \( r(nP) > r((n - 1)P) \), there exists a function \( f \in \mathcal{M}(G) \) such that

\[
(n - 1)P - E + \Delta f \not\geq 0, \quad np - E + \Delta f \geq 0.
\]

This, together with the fact that \( E(P) = 0 \), implies that \( f \) has a unique pole of order \( n \) at \( P \), that is \( n \in H_f(P) \).

**Remark 3.5.** In general, Theorem 3.4 fails when \( G \) has just one vertex \( P \) (in which case we have \( H_f(P) = \{0\} \) and \( H_r(P) = \mathbb{N} \)) and when \( G \) has multiple edges. An example of the last statement is given by the multigraph \( B_n \) with two vertices connected by \( n \) edges. For every vertex \( P \in V(B_n) \), it results \( H_f(P) = n\mathbb{N} \) and \( H_r(P) = \mathbb{N} \setminus \{1, \ldots, n - 1\} \), hence \( H_r(P) \nsubseteq H_f(P) \).

Following the strategy outlined in [14], as an application of Theorem 3.4 we calculate the rank Weierstrass set of complete and complete bipartite graphs from their functional Weierstrass set. In fact, in these two cases we have \( H_r(P) = H_f(P) \) for every vertex \( P \) of the graph.

**Lemma 3.6.** [14, Porism 2.11] Let \( G \) be a simple graph, let \( P \in V(G) \) be a vertex and let \( G - P \) be the graph \( G \) with the vertex \( P \) and its adjacent edges removed. If \( G - P \) is connected and \( f \in \mathcal{M}(G) \) is a function with a unique pole at \( P \), then \( f(P) < f(Q) \) for every \( Q \in V(G) \).

Let \( n \geq 1 \) and consider the complete graph \( K_{n+1} \).

**Lemma 3.7.** [14, Proposition 3.7] For every vertex \( P \in V(K_{n+1}) \), we have \( H_f(P) = \langle n, n + 1 \rangle \).
Corollary 3.8. For every vertex $P \in V(K_{n+1})$, we have $H_r(P) = \langle n, n+1 \rangle$.

Proof. By Lemma 3.7 and Theorem 3.4 we have $H_r(P) \subseteq H_f(P) = \langle n, n+1 \rangle$. Finally, from Lemma 2.5 we have $|N \setminus H_r(P)| = g(K_{n+1}) = |N \setminus \langle n, n+1 \rangle|$. □

Now let $n, m \geq 1$ and consider the complete bipartite graph $K_{n,m}$. The proof of the following lemma is inspired by the proof of [14, Proposition 3.7].

Lemma 3.9. Let $P \in V(K_{m,n})$ be a vertex of degree $n$, we have $H_f(P) = n \mathbb{N} \cup (n(m - 1) + \mathbb{N})$

Proof. If $n$ or $m$ is equal to 1, then $H_f(P) = \mathbb{N}$, so we assume that $n, m \geq 2$. We label the vertices of $K_{n,m}$ of degree $n$ by $P = P_1, P_2, \ldots, P_m$ and the vertices of degree $m$ by $Q = Q_1, \ldots, Q_n$. Let $f \in \mathcal{M}(K_{n,m})$ with a unique pole at $P$. By Lemma 3.6 the minimum of $f$ is attained at $P$. Without loss of generality we can assume $f(P) = 0$. Set $f(Q_i) = a + \alpha_i$ for $i \in \{1, \ldots, n\}$ with $a, \alpha_i \in \mathbb{N}$ and $\alpha_1 = 0$, and $f(P_i) = b + \beta_i$ for $i \in \{2, \ldots, m\}$ with $b, \beta_i \in \mathbb{N}$ and $\beta_2 = 0$. Now we have

$$ -\Delta_P f = na + \sum_{i=2}^n \alpha_i \geq 0, $$

$$ \Delta_Q f = a + (m - 1)(a - b) - \sum_{i=3}^m \beta_i \geq 0, $$

$$ \Delta_P^2 f = n(b - a) - \sum_{i=2}^n \alpha_i \geq 0. $$

Now if $a \geq b$, then from the third inequality $0 \geq n(b - a) \geq \sum \alpha_i \geq 0$. Hence $\alpha_i = 0$ for all $i \in \{2, \ldots, m\}$ and $-\Delta_P f = na \in n\mathbb{N}$. On the other hand, if $a < b$, then from the second inequality

$$ a + (m - 1)(a - b) \geq \sum \beta_i \geq 0 \Rightarrow a \geq (m - 1)(b - a) \geq m - 1. $$

This implies $-\Delta_P f = na + \sum \alpha_i \geq n(m - 1)$, that is $-\Delta_P f \in n(m - 1) + \mathbb{N}$. This proves the inclusion $H_f(P) \subseteq n\mathbb{N} \cup (n(m - 1) + \mathbb{N})$.

For the reverse inclusion, it is enough to note that, for the indicator function $f_P$, we have $\Delta f_P = -nP + \sum Q_i$. In addition, for every $t \in \{1, \ldots, n-1\}$

$$ \Delta \left( mf_P + \sum_{i=1}^t f_{Q_i} \right) = -(n(m - 1) + t)P + \sum_{i=2}^m tP_i + \sum_{i=t+1}^n mQ_i. $$

□
Proceeding similarly as in the proof of Corollary 3.8, we are able to calculate the rank Weierstrass set of complete bipartite graphs.

**Corollary 3.10.** Let $P \in V(K_{m,n})$ be a vertex of degree $n$, we have

$$H_r(P) = n\mathbb{N} \cup ((m-1)n + \mathbb{N})$$

**Remark 3.11.** The computation of the rank Weierstrass set of complete graphs (Corollary 3.8) was already implicit in the proof of [6, Theorem 8], a result that gives an upper bound for the gonality sequence of complete graphs. In fact, we note that the rank Weierstrass set of a complete graph coincides with its gonality sequence.

**Question 3.12.** Under which conditions on the graph $G$ and the vertex $P$ do we have $H_f(P) = H_r(P)$?

## 4 Functional Weierstrass sets

In this section, we characterize the subsets of $\mathbb{N}$ that arise as the functional Weierstrass sets of some graph or simple graph.

**Lemma 4.1.** Let $G$ be a graph and fix a vertex $P \in V(G)$. The functional Weierstrass set $H_f(P)$ is an additive submonoid of $\mathbb{N}$. Further, if $G$ is simple, then $H_f(P)$ is a numerical semigroup.

**Proof.** We always have $0 \in H_f(P)$. Further, for every $f, g \in \mathcal{M}(G)$, we have $\Delta(f + g) = \Delta f + \Delta g$, so $H_f(P)$ is closed under addition. Moreover, if $G$ is simple, from Theorem 3.4 we have $H_r(P) \subseteq H_f(P)$, and from Lemma 2.5 it follows $|\mathbb{N} \setminus H_f(P)| \leq |\mathbb{N} \setminus H_r(P)| = g(G)$. Therefore $H_f(P)$ is a numerical semigroup. \( \square \)

When the graph $G$ is not clear from the context, we denote the functional Weierstrass set by $H_f^G(P)$. For two subsets $A, B \subseteq \mathbb{N}$, we define

$$A + B = \{a + b : a \in A, b \in B\}.$$

**Proposition 4.2.** Let $G_1$ and $G_2$ be two graphs, and let $G$ be the graph obtained from $G_1$ and $G_2$ by the vertex gluing of $P_1 \in V(G_1)$ and $P_2 \in V(G_2)$, and denote by $P \in V(G)$ the identified vertex in $G$. Then

$$H_f^G(P) = H_f^{G_1}(P_1) + H_f^{G_2}(P_2).$$
Proof. We will consider $G_1$ and $G_2$ as subgraphs of $G$. For simplicity, set $S = H^G_f(P)$ and $S_i = H^G_{f_i}(P_i)$ for $i \in \{1, 2\}$. Let $x \in S_1$, then there exists $f \in \mathcal{M}(G_1)$ such that $\Delta(f) = D - xP_1$ for some effective divisor $D \geq 0$. Consider the extension $f'$ of $f$ to $G$ by setting $f'(v) = f(P)$ for all $v \in V(G_2) \setminus \{P\}$. Then $\Delta(f') = \Delta(f)$ and $x \in S$. This proves $S_1 \subseteq S$. Similarly we obtain $S_2 \subseteq S$, thus $S_1 + S_2 \subseteq S$ since $S$ is closed under addition.

On the other hand, let $x \in S$. Then there exists $f \in \mathcal{M}(G)$ such that $\Delta(f) = D - xP$ for some $D \geq 0$. Substituting $f$ with $f + a$ for some constant $a \in \mathbb{Z}$ if necessary, we can assume that $f(P) = 0$. For $i \in \{1, 2\}$, define

$$f_i \in \mathcal{M}(G_i) \quad f_i(v) = f(v) \quad \forall v \in V(G_i) \subseteq V(G).$$

Since $f(P) = 0$, we have $\Delta_v(f_i) = \Delta_v(f) \geq 0$ for all $v \in V(G_i) \setminus \{P\} \subseteq V(G)$, with $i \in \{1, 2\}$. Since every principal divisor has degree zero, we have

$$\Delta(f_1) = D_1 - x_1P, \quad \Delta(f_2) = D_2 - x_2P$$

for some $x_1, x_2 \in \mathbb{N}$ and some effective divisor $D_i \geq 0$ for $i \in \{1, 2\}$. From the definition we have $f = f_1 + f_2$, therefore $\Delta(f) = \Delta(f_1) + \Delta(f_2)$, hence $x = x_1 + x_2 \in S_1 + S_2$. \hfill \Box

Corollary 4.3. For every additive submonoid $M$ of $\mathbb{N}$ there exists a graph $G$ such that $M = H_f(P)$ for some $P \in V(G)$.

Proof. From [20, Lemma 2.3], every additive submonoid of $\mathbb{N}$ is finitely generated, so suppose that $M = \langle n_1, \ldots, n_e \rangle$. Now let $G$ be the graph with vertices $V(G) = \{P, P_1, \ldots, P_e\}$ where the vertex $P$ has $n_i$ edges connected to the vertex $P_i$ for every $i \in \{1, \ldots, e\}$. From Remark 3.3 and Proposition 4.2 it follows that $H_f(P) = n_1\mathbb{N} + \cdots + n_e\mathbb{N} = M$. \hfill \Box

Corollary 4.4. For every numerical semigroup $S$ there exists a simple graph $G$ such that $S = H_f(P)$ for some $P \in V(G)$.

Proof. Suppose that $S = \langle n_1, \ldots, n_e \rangle$. Set $m = \max(\mathbb{N} \setminus S) + 2$ and consider the complete bipartite graphs $K_{m,n_1}, \ldots, K_{m,n_e}$. Fix a vertex of degree $n_i$ in each graph and construct the graph $G$ by identifying these vertices, recursively applying the vertex gluing. Denote with $P$ the identified vertex in $G$. From Proposition 4.2 and Lemma 3.9 we obtain $H_f(P) = S$. \hfill \Box

Using Lemma 4.1 and Corollary 4.3 and 4.4 we now state the main result of this section.
Theorem 4.5. The functional Weierstrass sets of graphs (resp. simple graphs) are precisely the additive submonoids of \( \mathbb{N} \) (resp. numerical semigroups).

We close the section by calculating the multiplicity of the functional Weierstrass set of a simple graph. Recall that the multiplicity of a numerical semigroup \( S \) is the integer \( m(S) = \min(S \setminus \{0\}) \). Let \( G \) be a simple graph and fix a vertex \( P \in V(G) \). Denote with \( G - P \) the graph obtained from \( G \) by removing the vertex \( P \) and its adjacent edges.

Lemma 4.6. \cite[Theorem 2.10]{14} Suppose that \( G - P \) is connected. Then \( m(H_f(P)) = \deg(P) \).

Proposition 4.7. Let \( G_1, \ldots, G_m \) be the connected components of \( G - P \), and let \( \deg_{G_i} P \) be the number of edges incident with \( P \) in \( G_i \). Then
\[
m(H_f(P)) = \min \{ \deg_{G_i} P : i \in \{1, \ldots, m\} \}
\]

Proof. Let \( C_i \) be the graph obtained from \( G_i \) by adding the vertex \( P \) and the edges of \( G \) incident with \( P \) in \( G_i \). The graph \( G \) can be seen as the vertex gluing of the graphs \( C_i \) along \( P \). Now it is enough to apply Proposition 4.2 and Lemma 4.6. \( \square \)

5 Rank Weierstrass sets

Let \( G \) be a graph and fix a vertex \( P \in V(G) \). Define the function \( \lambda_P : \mathbb{N} \to \mathbb{N} \) by
\[
\lambda_P(k) = \min \{ n \in \mathbb{N} : r(nP) = k \}.
\]

Note that the function \( \lambda_P \) is an order preserving bijection between \( \mathbb{N} \) and \( H_r(P) \). Thus, \( \lambda_P \) completely determines \( H_r(P) \) and vice versa. We will write \( \lambda_P^G \) when the graph \( G \) is not clear from the context.

Proposition 5.1. Let \( G_1 \) and \( G_2 \) be two graphs and fix \( P_i \in V(G_i) \) for \( i \in \{1, 2\} \). Let \( G \) be the vertex gluing of \( P_1 \) and \( P_2 \), and let \( P \) be the identified vertex. Then
\[
\lambda_P^G(k) = \max \{ \lambda_{P_1}^{G_1}(k_1) + \lambda_{P_2}^{G_2}(k_2) : k_1 + k_2 = k \}.
\]
Proof. We will consider $G_1$ and $G_2$ as subgraphs of $G$. First, note that every divisor $E \in \text{Div}^k_+(G)$ can be decomposed as the sum $E = E_1 + E_2$ where $E_i \in \text{Div}^k_+(G_i)$ for $i \in \{1, 2\}$ with $k_1 + k_2 = k$. Further, if $\Delta f$ is a principal divisor in $G$, without loss of generality we can assume that $f(P) = 0$, so that $f = f_1 + f_2$ with $f_1 = 0$ in $G_2$ and $f_2 = 0$ in $G_1$. It follows that $\Delta f = \Delta f_1 + \Delta f_2$, in other words any principal divisor in $G$ is the sum of two principal divisors in $G_1$ and $G_2$ respectively.

Claim. Let $n, k \in \mathbb{N}$, the following statements are equivalent:

1. $|nP - E| \neq \emptyset$ for every $E \in \text{Div}^k_+(G)$,

2. $n \geq \lambda^G_{P_1}(k_1) + \lambda^G_{P_2}(k_2)$ for every $k_1 + k_2 = k$.

Proof of claim. First of all, set $n_i = \lambda^G_{P_i}(k_i)$ for $i \in \{1, 2\}$.

1) $\Rightarrow$ 2) Let $k_1, k_2 \in \mathbb{N}$ such that $k_1 + k_2 = k$. By the definition of $n_i$, there exists $E_i \in \text{Div}^k_+(G_i)$ such that $|(n_i - 1)P - E_i| = \emptyset$ for $i \in \{1, 2\}$. Set $E = E_1 + E_2 \in \text{Div}^k_+(G)$. By hypothesis we have

$$nP - E + \Delta f = nP + (\Delta f_1 - E_1) + (\Delta f_2 - E_2) \geq 0,$$

for some $f \in \mathcal{M}(G)$, with $f = f_1 + f_2$ as described above. Assume by contradiction $n < n_1 + n_2$, this means that, for some $i \in \{1, 2\}$, we have $(n_i - 1)P - E_i + \Delta f_i \geq 0$, that is $|(n_i - 1)P - E_i| \neq \emptyset$, contradiction.

2) $\Rightarrow$ 1) Let $E \in \text{Div}^k_+(G)$, then $E = E_1 + E_2$ with $E_i \in \text{Div}^k_+(G_i)$ for $i \in \{1, 2\}$ and $k_1 + k_2 = k$. By the definition of $n_i$, there exists $f_i \in \mathcal{M}(G_i)$ such that $n_i P - E_i + \Delta f_i \geq 0$ for $i \in \{1, 2\}$. Without loss of generality, we can assume that $f_1(P) = f_2(P) = 0$, set $f = f_1 + f_2$, we have

$$nP - E + \Delta f \geq \sum_{i \in \{1, 2\}} (n_i P - E_i + \Delta f_i) \geq 0$$

that is $|nP - E| \neq \emptyset$. $\square$

Now write

$$\lambda^G_{P_i}(k) = \min \{n \in \mathbb{N} : r(nP) \geq k\}$$

$$= \min \{n \in \mathbb{N} : |nP - E| \neq \emptyset, \forall E \in \text{Div}^k_+(G)\}$$

$$= \min \{n \in \mathbb{N} : n \geq \lambda^G_{P_1}(k_1) + \lambda^G_{P_2}(k_2), \text{ for every } k_1 + k_2 = k\}$$

$$= \max \{\lambda^G_{P_1}(k_1) + \lambda^G_{P_2}(k_2) : k_1 + k_2 = k\}.$$ $\square$
Remark 5.2. We note that the notion of rank Weierstrass set implicitly appears in [18, Section 3.2]. In fact, the so called Weierstrass partition of the zero divisor at a marked point $P$ encodes the information of the rank Weierstrass set $H_r(P)$ (see [18, Definition 3.11]). Further, we note that one of the main techniques used in [18] to study the behaviour of Weierstrass partitions is the (analogue of) vertex gluing of an arbitrary metric graph with a cycle.

Theorem 5.3. Let $e_1 \geq e_2 \geq \cdots \geq e_n \geq 0$ be integers and set $s_i = \sum_{j=1}^{i} e_j$. There exists a simple graph $G$ with a vertex $P \in V(G)$ such that

$$H_r(P) = \{0, s_1, s_2, \ldots, s_{n-1}\} \cup (s_n + \mathbb{N}).$$

Proof. We proceed by induction on $n$. For the base case $n = 1$, by Corollary 3.10 it is enough to consider the graph $K_{2,e_1}$ and a vertex $P$ of degree $e_1$. Now assume that the theorem is true for $n - 1$, and let $G'$ be a graph with a vertex $P_1$ such that

$$H_r^{G'}(P_1) = \{0, s_1, \ldots, s_{n-1}\} \cup (s_n + \mathbb{N}).$$

Consider the graph $K_{2,e_n}$ and fix a vertex $P_2$ of degree $e_n$. Let $G$ be the vertex gluing of $P_1$ and $P_2$. From Corollary 3.10 we have

$$H_r^{K_{2,e_n}}(P_2) = \{0\} \cup (e_n + \mathbb{N}).$$

Now apply Proposition 5.1 to the vertex gluing $G$ of $P_1$ and $P_2$. \hfill \Box

Remark 5.4. In the proof of Theorem 5.3 we glued together complete bipartite graphs $K_{2,e_i}$ along vertices of degree $e_i$. However, we could have used any graph of genus $e_i - 1$ with a fixed non-Weierstrass point, i.e. with a fixed vertex in which the Weierstrass set is $\mathbb{N} \setminus \{1, \ldots, e_i - 1\}$.

Remark 5.5. From Theorem 5.3 it follows that every Arf numerical semigroup is the rank Weierstrass set of some graph. In fact, it is enough to choose the sequence $e_1 \geq \cdots \geq e_n$ to be the multiplicity sequence of the given Arf numerical semigroup. See [4, Section 2] for more information about Arf numerical semigroups and their multiplicity sequence.

Theorem 5.3 can be used to construct families of graphs with rank Weierstrass set that is not a semigroup. We now describe an example of such a graph.
Example 5.6. Let $n = 3$ and $(e_1, e_2, e_3) = (3, 2, 2)$. Following the idea in the proof of Theorem 5.3 we consider the graph $G$ (Figure 1) obtained as the vertex gluing of $K_{2,3}$ and two copies of $K_{2,2}$. Let $P \in V(G)$ be the identified vertex of degree 7. We have

$$H_r(P) = \{0, 3, 5, 7\} \cup (8 + \mathbb{N}).$$

Note that $H_r(P)$ is not a semigroup, since $3 \in H_r(P)$, but $3 + 3 = 6 \notin H_r(P)$.

![Figure 1](image)

Theorem 5.3 gives a sufficient condition for a subset of $\mathbb{N}$ to be the rank Weierstrass set of some graph. We now provide an easy necessary condition.

Proposition 5.7. Let $G$ be a graph and fix a vertex $P \in V(G)$. For every $n, k \in \mathbb{N}$ we have

$$|H_r(P) \cap [1, nk]| \geq k |H_r(P) \cap [1, n]|.$$ 

Proof. From the definition we have $r(nP) = |H_r(P) \cap [1, n]|$, further from Lemma 2.1 $r(nkP) \geq k r(nP)$. \qed

Question 5.8. Can we characterize the cofinite subsets $H \subseteq \mathbb{N}$ that are the rank Weierstrass set of some graph?

In [3] the notion of harmonic morphism between graphs is studied. It is a discrete analogue of morphisms of curves. In particular, in this context it makes sense to talk about hyperelliptic graphs and double covers.

Classically, we know that a curve $X$ is hyperelliptic if and only if there exists $P \in X$ such that $2 \in H(P)$. An analogous fact is proved in [21, Theorem A]: a curve $X$ of genus $g \geq 6\gamma + 4$ is a double cover of a curve of genus $\gamma \geq 1$ if and only if there exists $P \in X$ such that $H(P)$ has $\gamma$ even gaps.
Question 5.9. Can we find an analogue of [21, Theorem A] for graphs?

Acknowledgments. I would like to thank Diane Maclagan, Yoav Len and Victoria Schleis for a careful reading and comments on an earlier version of this manuscript, and Marta Panizzut, Gretchen Matthews, Cong X. Kang and Nathan Pflueger for useful discussions and email exchanges.
