Accuracy of lintula score versus alvarado score in diagnosis of acute appendicitis in Al-yarmouk teaching hospital

Dr. Ali Saadi Omar and Dr. Sattar Jabbar Kadhim

DOI: https://doi.org/10.33545/surgery.2020.v4.i4a.532

Abstract

Background: Acute appendicitis is a common and urgent surgical illness with different manifestations, generous overlap with other clinical symptoms. Alvarado score uses mainly clinical findings and laboratory values to assess the presence of acute appendicitis. Lintula scoring system has the inherent advantage in that it does not require laboratory parameters.

Aim of study: To compare between two applied scoring systems (Alvarado and Lintula) in the diagnosis of acute appendicitis.

Methods: A prospective observational study that was conducted in the Department of General Surgery at Al-Yarmouk Teaching Hospital/Baghdad during the period of 10 months from 1st of April 2019 till 1st of February 2020. It included 160 patients attended the outpatient clinic or the emergency department with signs and symptoms suggestive of acute appendicitis.

Results: In this study, most of the patients (88.8%) were underwent open appendectomy and follow up after discharge. More than half of the operated cases (95.8%) were diagnosed as acute appendicitis. Cut-off point of lintula scoring system was (21), so lintula score > 21 is predictive for diagnosis of appendicitis. Lintula scoring system was 67% sensitive, 58.3% specific, and 63.1% accurate. Cut-off point of Alvarado scoring system was (7), so Alvarado score > 7 is predictive for diagnosis of appendicitis. Alvarado scoring system was 82.7% sensitive, 55% specific, and 77.9% accurate.

Conclusion: Lintula score is comparable to Alvarado score in sensitivity, specificity, and accuracy for the diagnosis of acute appendicitis. Lintula score is simple, non-invasive way to be used in resource limited conditions, but Alvarado score is still more statistically better than Lintula score.

Keywords: Alvarado score, Lintula score, appendicitis

Introduction

Acute Appendicitis is defined as an inflammation of the inner lining of the vermiform appendix that spreads to its other parts. It is a common and urgent surgical illness with protean manifestations, generous overlap with other clinical syndromes, and significant morbidity, which increases with diagnostic delay. In fact, despite diagnostic and therapeutic advancement in medicine, appendicitis remains a clinical emergency and is one of the more common causes of acute abdominal pain [1]. Appendicitis may occur for several reasons, such as an infection of the appendix, but the most important factor is the obstruction of the appendicular lumen [2]. No single sign, symptom, or diagnostic test accurately confirms the diagnosis of appendiceal inflammation in all cases, and the classic history of anorexia and periumbilical pain followed by nausea, right lower quadrant (RLQ) pain, and vomiting occurs in only 50% of cases [3].

Incidence

Appendicitis is most common between the ages of 5 and 40; the median age is 28 [4]. Risk factors include being male, higher household income and living in a rural area. In 2013, it resulted in 72,000 deaths globally, down from 88,000 in 1990 [5]. In the United States, there were nearly 293,000 hospitalizations involving appendicitis in 2010 [6]. Appendicitis is one of the most frequent diagnoses for emergency department visits resulting in hospitalization among children ages 5–17 years in the United States [7]. In the UK, around 42,000 to 47,000 operations for appendicitis were performed yearly between 2007 and 2012. Large studies from the UK and US have shown that complicated appendicitis is found at surgery in around 16.5% to 24.4% of cases [8].
In Asian and African countries, the incidence of acute appendicitis is probably lower because of the dietary habits of the inhabitants of these geographic areas. The incidence of appendicitis is lower in cultures with a higher intake of dietary fiber. The incidence of appendicitis gradually rises from birth, peaks in the late teen years, and gradually declines in the geriatric years [11]. Lymphoid hyperplasia is observed more often among infants and adults and is responsible for the increased incidence of appendicitis in these age groups. Younger children have a higher rate of perforation, with reported rates of 50-85%. The median age at appendectomy is 22 years. Although rare, neonatal and even prenatal appendicitis have been reported. Clinicians must maintain a high index of suspicion in all age groups [11].

Etiology

Often, the exact etiology of acute appendicitis is unknown. When the appendiceal lumen gets obstructed, bacteria will build up in the appendix and cause acute inflammation with perforation and abscess formation [10]. The cause of appendicitis is usually from an obstruction of the appendiceal lumen. This can be from an appendicolith (stone of the appendix), or from some other mechanical etiologies. Appendiceal tumors such as carcinoid tumors, intestinal parasites, and hypertrophied lymphatic tissue are all known causes of appendiceal obstruction and appendicitis [10].

Pathophysiology

The pathophysiology of appendicitis likely result from obstruction of the appendiceal lumen, which results in inflammation, localized ischemia, perforation, and the development of a contained abscess or frank perforation with resultant peritonitis. This obstruction may be caused by lymphoid hyperplasia, infections (parasitic), fecaliths, or benign or malignant tumors [11]. If appendiceal obstruction persists, intraluminal pressure rises ultimately above that of the appendiceal veins, leading to venous outflow obstruction. As a consequence, appendiceal wall ischemia begins, resulting in a loss of epithelial integrity and allowing bacterial invasion of the appendiceal wall. Within a few hours, this localized condition may worsen because of thrombosis of the appendicular artery and veins, leading to perforation and gangrene of the appendix. As this process continues, a peri-appendicular abscess or peritonitis may occur [13]. Bacterial overgrowth occurred at the time of obstruction, with aerobic organisms predominating in early appendicitis and mixed aerobes and anaerobes later in the course. Common organisms include Escherichia coli, Peptostreptococcus, Bacteroides, and Pseudomonas [12].

The scoring system for predicting acute appendicitis

They have the potential to reduce diagnostic error, increase quality and enhance appropriate patient care [13].

♦ The Alvarado score

Alvarado score is the first and most widely known scoring method, the accuracy of which has been clinically approved [14]. It uses mainly clinical findings and laboratory values to assess the presence of acute appendicitis [15]. It has been shown that Alvarado score prevents the delay in therapy and reduced the negative appendectomy rate. Although Alvarado score has a high accuracy rate [16]. The original Alvarado score describes a possible total of 10 points, but those medical facilities that are unable to perform a differential white blood cell count, are using a Modified Alvarado Score with a total of 9 points which is not as accurate as the original score [17]. Further investigations, such as ultrasound and computed tomography (CT) scanning, are recommended when probability of appendicitis is in the intermediate range [18].

♦ The Lintula score

The Lintula scoring tools were developed in an attempt to assist clinicians in distinguishing acute appendicitis from other causes of abdominal pain, with the aim of reducing the negative appendectomy rate [19]. Acute abdominal pain patients with a total score of ≤15 on the Lintula scales have a lower probability of acute appendicitis and thus do not require hospitalization. Patients with scores of ≥21, have a higher probability of acute appendicitis requiring emergency appendectomy. Patients with Lintula scores between 16 and 20 are suspected cases for acute appendicitis; close inpatient follow-up is recommended for this group [20]. The Lintula scoring system is a simple, non-invasive and cost effective way of narrowing down the diagnosis of acute appendicitis with potential utility in resource limited settings [21].

Aim of the study

To compare between two applied scoring systems (Alvarado and Lintula) in the diagnosis of acute appendicitis.

Patients and method

This is a prospective observational study that was conducted in the Department of General Surgery at Al-Yarmouk Teaching Hospital / Baghdad during the period of 10 months from 1st of April 2019 till 1st of February 2020. The study included 160 patients attended the outpatient clinic or the emergency department with signs and symptoms suggestive of acute appendicitis (lower abdominal and/or right iliac fossa pain).

Exclusion criteria

- Age < 5 years.
- Pregnant ladies.
- Patients with features of generalized peritonitis.
- Previous history of intra-abdominal surgery.

Data collection tools

A questionnaire applied to all enrolled participants to collect the needed information. It includes questions to gather the following information:

- Age, gender, and occupation.
- Past medical and surgical history.
- Symptoms: Anorexia. Vomiting. Pain (Site, shifting, rebound, and severity).
- Examination (General and vital signs, temperature, abdominal examination and bowel sound).
- Investigation results (Complete blood count).

Ethical considerations and official approvals

Verbal permission was obtained from each patient prior to collecting data, and information were anonymous. Names were removed and replaced by identification codes. All information kept confidential in a password secured laptop and data used exclusively for the research purposes.

Statistical analysis

The data analyzed using Statistical Package for Social Sciences
(SPSS) version 25. The data presented as mean, standard deviation and ranges. Categorical data presented by frequencies and percentages. Chi square test was used to assess the association between provisional diagnosis and certain parameters of both scores. Receiver operating characteristic (ROC) curve analysis was used for prediction of Alvarado and lintula scores as diagnostic of acute appendicitis. Pearson’s correlation test \((r)\) was used to assess correlation between Alvarado and lintula scores. A level of \(P – \text{value} \leq 0.05\) was considered significant.

**Results**

Figure 1 shows the distribution of study patients by decision of appendectomy. Most of the patients (142 patients, 88.8%) had appendectomy.

![Fig 1: Distribution of study patients by decision of appendectomy](image)

**Diagnosis**

Table 1 shows the final diagnosis regarding those who underwent appendectomy. We noticed that majorities of the operated cases (95.8%) diagnosed as acute appendicitis (simple+ acute+ gangrenous+ catarrhal appendicitis), while the rest (4.2%) were not appendix (ovarian and pelvic collection).

![Table 1: Final diagnosis regarding those who underwent appendectomy](image)

**Alvarado scoring system**

The distribution of Alvarado scoring system is shown in figure (2). In this study the highest proportion of study patients were scored between 7 - 8 by Alvarado scoring system (41.3%).

![Fig 2: Distribution of Alvarado scoring system](image)

**Lintula scoring system**

The association between lintula scoring system parameters and the final diagnosis is shown in table (2). We noticed that 85.9% of patients who had body temperature \(\geq 37.5 \, ^\circ\text{C}\), 78.9% of those who experienced guarding during examination, and 80.7% of those who showed rebound tenderness during examination were diagnosed with appendicitis with significant associations between final diagnosis and all of body temperature \((P= 0.001)\), guarding \((P= 0.017)\), and rebound tenderness \((P= 0.04)\). No statistical significant associations between final diagnosis and all other parameters \((P\geq 0.05)\).

![Fig 3: Distribution of lintula scoring system](image)

The cut-off point of lintula scoring system was (21), so lintula score > 21 is predictive for diagnosis of appendicitis as a large...
significant area under the curve (AUC= 64.5%) indicating significant association between higher score of lintula score and diagnosis of appendicitis. Lintula scoring system was 67% sensitive, 58.3% specific, and 63.1% accurate as a predictor for diagnosis of appendicitis.

Table 3: Diagnostic accuracy of lintula scoring system for diagnosis of appendicitis

| Lintula scoring system | Cut-off value | Sensitivity | Specificity | PPV | NPV | Accuracy |
|------------------------|---------------|-------------|-------------|-----|-----|----------|
|                        | 21            | 67%         | 58.3%       | 66.3% | 59.2% | 63.1%    |

In table 4, the cut-off point of Alvarado scoring system was (7), so Alvarado score > 7 is predictive for diagnosis of appendicitis as a large significant area under the curve (AUC= 85.7%) indicating significant association between higher score of Alvarado score and diagnosis of appendicitis. Alvarado scoring system was 82.7% sensitive, 55% specific, and 77.9% accurate as a predictor for diagnosis of appendicitis.

Table 4: Diagnostic accuracy of Alvarado scoring system for diagnosis of appendicitis

| Alvarado scoring system | Cut-off value | Sensitivity | Specificity | PPV  | NPV  | Accuracy |
|------------------------|---------------|-------------|-------------|------|------|----------|
|                        | 7             | 82.7%       | 55%         | 74.2% | 52.2% | 77.9%    |

The correlation between Alvarado and lintula scoring systems is shown in table (5) and figure (4). Statistically significant moderate positive correlation was detected between Alvarado and lintula scoring systems (r= 0.562, P= 0.001).

Table 5: Correlation between Alvarado and lintula scoring systems

| Lintula scoring system | Alvarado scoring system |
|------------------------|-------------------------|
|                        | r | P-Value |
|                        | 0.562 | 0.001 |

Fig 4: Correlation between Alvarado and lintula scoring systems

Discussion

In the present study. Most of the patients underwent appendectomy (88.8%). Also, majorities of them were diagnosed as acute appendicitis (95.8%) and normal appendix found in 4.2% of the participants.

In comparison to other studies, a comparable result observed in Ojuka et al. study in 2017, in which they found that majority of their respondents underwent appendectomy (85.9%); 9.9% were discharged while 4.2% underwent formal laparotomy, also noticed that 42.6% of the patients who underwent appendectomy had uncomplicated acute appendicitis, while 16.4% were found to have a normal appendix [21]. Differently, Kirkil and colleagues in their study in 2013, reported a lower result, as noticed that appendectomy was performed in 64 of the 114 patients included in their study (56.1%). Histopathological examination was negative for acute appendicitis in 11 of these 64 patients (17%) [22]. Furthermore, a different results observed in Kanumba et al. study in 2011, in which all the participants (127 patients) underwent appendectomy. Histopathological examination yielded a higher results, as confirmed appendicitis in 85 patients (66.9%) and the remaining 42 patients had normal appendix giving a negative appendectomy rate of 33.1% [23]. In this study, the highest proportion of study patients were scored between 21 – 25 by Lintula scoring system (48.8%). By comparison to other studies, a lower results observed in Ojuka et al. study in 2017, in which found that minority of the respondents (19.72%) had a Lintula index of between 26 and 28 [21]. In this study, association between Lintula scoring and final diagnosis showed that 85.9% are febrile patients (≥ 37.5 °C), 78.9% of those who experienced guarding, and 80.7% of those had rebound tenderness were diagnosed with appendicitis with significant associations with body temperature (P= 0.001), guarding (P= 0.017), and rebound tenderness (P= 0.04), while no statistical significant associations between final diagnosis and all other parameters (P ≥ 0.05).

Ojuka and colleagues in their study in 2017, observed a comparable result, when noticed that no association between gender and whether or not the respondents had appendicitis (p = 0.155). Also observed a non-significant association between pain intensity and final diagnosis (p= 0.245) and pain relocation was not related to final diagnosis (p = 0.711) [21]. In this study, ROC curve analysis showed that cut-off point of lintula scoring system was (21), so Lintula score > 21 is predictive for diagnosis of appendicitis. Lintula scoring system was 67% sensitive, 58.3% specific, and 63.1% accurate. In comparison to other studies, current results were slightly sensitive than results observed in Ojuka et al. study in 2017, as found at a cut-off score of 21 for the Lintula scoring system, 9.8% of patients would have been falsely positive. At this cut-off point, the specificity, sensitivity and PPV of the Lintula scoring systems were 60.8%, 60% and 79.5% respectively [21]. A more specific findings observed in Kanumba E et al., studies in 2011, in which the PPV for a score of 21 was 100%, with an accuracy of 78%. The cut-off limit of 15 had a PPV of 88.5% and a NPV of 77.8%. Finally found the optimal cut-off point to be 12 points, with a PPV of 87.2% and a NPV of 87.8% [23]. On the other hand, Kahaner and colleagues in ROC curve analysis included in their study in 2016, observed at cut-off point of Lintula score 16, sensitivity, specificity and PPV were 59.3%, 80.1% and 57.1% respectively, which were more specific despite a lower score value [21].

A different results observed in Özsoy et al. study in 2017, in which the highest proportion of the participants had an Alvarado score between 5-7 which constituted 55.1% [25]. In the present study, association between Alvarado scoring and the final diagnosis showed that 85.9% of febrile patients (≥ 37.5 °C), and 80.7% of those had rebound tenderness were diagnosed with appendicitis with significant associations between final diagnosis and body temperature (P= 0.001), and rebound tenderness (P= 0.04), but no statistical significant associations between final diagnosis and all other parameters (P ≥ 0.05).

In the present study, ROC curve analysis showed that cut-off point of Alvarado scoring system was (7), so Alvarado score > 7 is predictive for diagnosis of appendicitis. Alvarado scoring system was 82.7% sensitive, 55% specific, and 77.9% accurate as a predictor for diagnosis of appendicitis. In comparison to other studies, current results were more specific in diagnosis of appendicitis when compared to results observed in Ojuka et al.
study in 2017, as found at a cut-off score of 7 for the Alvarado scoring system, 14.8% of patients would have been falsely positive. At this cut-off point, the sensitivity, specificity and PPV of the Alvarado scoring systems were 84.3%, 35% and 76.8% respectively [21].

In Özsoy et al. study in 2017, ROC curve indicated that cut-off value of Alvarado score for correct diagnosis of appendicitis is 7, in accordance to the current study, but was less sensitive but more specific in determining the diagnosis of appendicitis, as found that sensitivity, specificity and PPV were 59.2%, 83.9% and 93.7% respectively [25]. A less sensitive, more specific results observed in Mandeville et al., study in 2011, in which 287 patients found that an Alvarado cutoff score of 7 or higher would give 118 correct diagnoses (41%); sensitivity, 76%; specificity, 72%; and PPV, 76% [26]. Finally, more specific and sensitive results observed in Pogorelic et al. study in 2015, in which a total of 311 patients were included in the study. Based on the ROC curve analysis, a cutoff value for Alvarado scoring systems was 7. In patients with acute appendicitis and Alvarado score of 7 or higher, the correct diagnosis would have been set in 75% of patients (sensitivity, 89%; specificity, 59%; positive predictive value, 93.1%) [27].

The differences in the above mentioned studies may be explained by the different populations of patients enrolled, difference in age of participants, because of age-related changes seen in the gastrointestinal tract. As the number and function of the myenteric enteric nervous system decrease with age, there is a decrease in the motility of the gastrointestinal system, and constipation is seen in one-fourth of the individuals over 65 years of age [28], difference in gender as female patients with tenderness in the right lower quadrant can potentially have a variety of conditions, including pelvic infectious disease and other gynecological pathologies [29], the experience of surgeon in determining the disease through clinical examination, investigation done and the experience of the operator of such investigation.

In the current results also, the correlation between Alvarado and Lintula scoring, showed a statistically significant moderate positive correlation between Alvarado and Lintula scoring systems (r= 0.562, P= 0.001). Ojuka and colleagues in their study in 2017, agreed to the current results in that a strong positive correlation between Lintula score and Alvarado score (p= 0.001). They observed that a high value of Lintula score was associated with a high value of Alvarado score (p=0.001). Another agreement observed in Kirkil et al. study in 2013, in which observed that Alvarado and Lintula scores correlated highly with the histopathological diagnosis of acute appendicitis (p=0.001 and p=0.000, respectively) [22].

**Conclusion:** This study approved that Lintula score is comparable to Alvarado score in sensitivity, specificity, and accuracy for the diagnosis of acute appendicitis. Lintula score is simple, non-invasive way to be used in resource limited conditions.
