(Dated: July 30, 2008)

We calculate the upper critical field, $H_{c2}(T)$, due to the orbital pair breaking in disordered superconductors without inversion symmetry. Differences from the usual centrosymmetric case are highlighted. The linearized gap equations in magnetic field, with the singlet and triplet pairing channels mixed by impurity scattering, are solved exactly for a cubic crystal.

PACS numbers: 74.20.-z, 74.25.Op

I. INTRODUCTION

Recently, superconductivity has been discovered in a number of compounds lacking inversion symmetry, such as CePt$_3$Si (Ref. 1), Ulr (Ref. 2), CeRhSi$_3$ (Ref. 3), CeIrSi$_3$ (Ref. 4), Li$_2$(Pd$_{3-x}$Pt$_x$)B (Ref. 5), and many others. Much of the theoretical work in the field has focussed on searching for the features which are specific to noncentrosymmetric systems. These include the magnetoelectric effect, a large residual spin susceptibility and reduced paramagnetic limiting and various novel nonuniform superconducting states.

In this paper we study the effects of the absence of inversion symmetry on the upper critical field, $H_{c2}(T)$, at arbitrary temperature. We assume the pairing to be of the Bardeen-Cooper-Schrieffer (BCS) type, and include only the orbital pair breaking. The main qualitative difference from the centrosymmetric case is that the spin-orbit (SO) coupling of electrons with the crystal lattice changes the nature of single-electron states, lifting spin degeneracy of the energy bands. Then even scalar impurities can mix the singlet and triplet channels in the Cooper pair propagator, thus making the theory considerably more complicated. The derivation of the $H_{c2}$ equations for arbitrary noncentrosymmetric crystal symmetry is presented in Sec. II, below, with some of the technical details relegated to Appendices A and B. In Sec. III, we apply the general equations to a cubic superconductor with the point group $G = O$. Assuming that both the band structure and the SO coupling are fully isotropic, we are able to exactly solve the coupled equations for the singlet and triplet channels, obtain the $H_{c2}$ equation in a closed form, and derive analytical expressions for the upper critical field in the “dirty” limit. This isotropic model clearly shows the deviations from the usual, i.e. centrosymmetric BCS, case, for which the upper critical field was calculated in the classic papers by Helfand, Werthamer, and Hohenberg in 1960s (Refs. 17, 18).

Sec. IV contains a discussion of our results. The magnetic phase diagram of noncentrosymmetric superconductors has been discussed previously in several works. The upper critical field for a clean three-dimensional Rashba superconductor was calculated in Ref. 15, while the effects of disorder in the Ginzburg-Landau regime were studied in Ref. 14. Two-dimensional case, in which only the paramagnetic pair breaking is present, was considered in Ref. 20. Recently, $H_{c2}$ at all temperatures was calculated in Ref. 21, neglecting the impurity-induced triplet channel in the pair propagator in the limit when the SO band splitting is small compared with the Fermi energy. In this paper, we relax this last condition and include both the singlet and triplet channels.

Throughout the paper we use the units in which $\hbar = k_B = 1$.

II. DERIVATION OF $H_{c2}$ EQUATIONS: GENERAL CASE

Let us consider a noncentrosymmetric superconductor with the Hamiltonian given by $H = H_0 + H_{imp} + H_{int}$. The first term,

$$H_0 = \sum_k [\epsilon_0(k) \delta_{\alpha\beta} + \gamma(k) \sigma_{\alpha\beta}] a_k^\dagger a_k,$$

(1)

describes non-interacting electrons in the crystal lattice potential, where $\alpha, \beta = \uparrow, \downarrow$ are spin indices, $\epsilon_0(k)$ is the quasiparticle energy counted from $E_F$, and $\sigma$ are the Pauli matrices. In Eq. (1) and everywhere below, summation over repeated spin indices is implied, while summation over space and band indices is always shown explicitly. The second term in Eq. (1), with $\gamma(k) = -\gamma(-k)$, describes a Rashba-type (or antisymmetric) SO coupling of electrons with the crystal lattice. In addition, there might be a usual (symmetric) SO coupling, present even in centrosymmetric crystals. If the latter is included, then $\alpha, \beta$ in Eq. (1) should be interpreted as pseudospin projections. Diagonalization
of $H_0$ yields two non-degenerate bands labelled by the helicity $\lambda = \pm$:

$$\xi_\lambda(k) = \epsilon_0(k) + \lambda |\gamma(k)|.$$  

(2)

The Fermi velocities in the two bands are given by $v_\lambda(k) = \partial \xi_\lambda / \partial k$. The Fermi-level densities of states are defined in the usual way by $N_\lambda = V^{-1} \sum_k \delta [\xi_\lambda(k)]$ ($V$ is the system volume), and the difference between $N_+$ and $N_-$ is characterized by a parameter

$$\delta = \frac{N_+ - N_-}{N_+ + N_-}.$$  

(3)

If the SO coupling is small compared with the Fermi energy, then $\delta \sim \mathcal{O}(E_{SO}/\epsilon_F)$, where $E_{SO} = 2 \max_k |\gamma(k)|$ is a measure of the SO band splitting.

Scattering of electrons at isotropic scalar impurities is introduced according to

$$H_{imp} = \int d^3r \, U(r) \psi^\dagger_\sigma(r) \psi_\sigma(r).$$  

(4)

The random potential $U(r)$ has zero mean and is characterized by the correlator $\langle U(r)U(r') \rangle = n_{imp}U^2 \delta(r - r')$, where $n_{imp}$ is the impurity concentration and $U_0$ has the meaning of the strength of an individual point-like impurity.

Neglecting the paramagnetic pair breaking, which is a good assumption in many bulk noncentrosymmetric materials, the effect of a uniform external magnetic field $H$ is described by the Peierls substitution:

$$\hat{h} = \epsilon_0(K) + \gamma(K) \hat{\sigma} + U(r),$$  

(5)

where $K = -i\nabla + (e/c)A(r)$, and $e$ is the absolute value of the electron charge.

We describe the pairing interaction by a BCS-like Hamiltonian:

$$H_{int} = -V \int d^3r \, \psi^\dagger_\uparrow(r) \psi^\dagger_\downarrow(r) \psi_\downarrow(r) \psi_\uparrow(r),$$  

(6)

where $V > 0$ is the coupling constant. In this model, the superconducting order parameter is represented by a single complex function $\eta(r)$, see Ref. [24]. The critical temperature at a given field, or inversely the upper critical field, $H_{c2}(T)$, at a given temperature, is found from the condition that the linearized gap equation

$$\left( \frac{1}{V} - T \sum_n \langle \hat{X}(\omega_n) \rangle \right) \eta(r) = 0$$  

(7)

has a nontrivial solution. Here $\omega_n = (2n + 1)\pi T$ is the fermionic Matsubara frequency, the prime in the second term means that the summation is limited to $|\omega_n| \leq \omega_c$, where $\omega_c$ is the BCS frequency cutoff, and the operator $\hat{X}(\omega_n)$ is defined by the following kernel:

$$X(r, r'; \omega_n) = \frac{1}{2} \langle \text{tr} \, \hat{g}^\dagger \hat{G}(r, r'; \omega_n) \hat{g} \hat{G}^T(r, r'; -\omega_n) \rangle_{\text{imp}},$$  

(8)

where $\hat{g} = i\hat{\sigma}_2$. The angular brackets denote the impurity averaging, and $\hat{G}(r, r'; \omega_n)$ is the Matsubara Green’s functions of electrons in the normal state, which satisfies the equation

$$(i\omega_n - \hat{h}) \hat{G}(r, r'; \omega_n) = \delta(r - r'),$$  

(9)

where the single-particle Hamiltonian $\hat{h}$ is given by expression (5).

At zero field, Eq. (9) yields the following expression for the average Green’s function:

$$\hat{G}(k, \omega_n) = \sum_{\lambda = \pm} \hat{\Pi}_\lambda(k) \hat{G}_\lambda(k, \omega_n),$$  

(10)

where

$$\hat{\Pi}_\lambda(k) = \frac{1 + \lambda \gamma(k) \hat{\sigma}}{2}$$  

(11)
are the band projection operators \( \hat{\gamma} = \gamma / |\gamma| \), and

\[
G_\lambda(k, \omega_n) = \frac{1}{i\omega_n - \xi_\lambda(k) + i\Gamma \text{sign} \omega_n},
\]

(12)

are the electron Green’s functions in the band representation. Here \( \xi_\lambda(k) \) is the quasiparticle dispersion in the \( \lambda \)th band, see Eq. (2), \( \Gamma = 1/2\tau \) is the elastic scattering rate, \( \tau = (2\pi n_{\text{imp}} U_0^2 N_F)^{-1} \) is the electron mean free time due to impurities, and

\[
N_F = \frac{N_+ + N_-}{2}.
\]

(13)

The impurity average of the product of two Green’s functions in Eq. (8) can be represented graphically by the ladder diagrams, see Fig. 1. We assume the disorder to be sufficiently weak for the diagrams with crossed impurity scattering can induce also a nonzero spin-triplet component: Using Eqs. (17), we obtain:

\[
d(r, \omega_n) = d_0(r, \omega_n) \hat{g} + d(r, \omega_n) \hat{g}.
\]

(16)

we obtain a system of four integral equations for \( d_a(r, \omega_n) \), where \( a = 0, 1, 2, 3 \):

\[
\sum_{b=0}^{3} [\delta_{ab} - \Gamma \hat{Y}_{ab}(\omega_n)] d_b(r, \omega_n) = \eta(r) \delta_{a0}.
\]

(17)

Here the operators \( \hat{Y}_{ab}(\omega_n) \) are defined by the kernels

\[
Y_{ab}(r, r'; \omega_n) = \frac{1}{2\pi N_F} \text{tr} \hat{g}_a \hat{G}(r, r'; \omega_n) \hat{g}_b \hat{G}^T(r, r'; -\omega_n),
\]

(18)

with \( \hat{g}_0 = \hat{g} \), and \( \hat{g}_i = \hat{g}_i \) for \( i = 1, 2, 3 \). We see that, in addition to the spin-singlet component \( d_0(r, \omega_n) \), impurity scattering can induce also a nonzero spin-triplet component \( d(r, \omega_n) \). The gap equation (7) contains only the singlet component: Using Eqs. (17), we obtain:

\[
\frac{1}{N_F} \eta(r) = \pi T \sum_n \frac{d_0(r, \omega_n) - \eta(r)}{\Gamma} = 0.
\]

(19)

We would like to note that the triplet component does not appear in the centrosymmetric case. Indeed, in the absence of the Zeeman interaction the spin structure of the Green’s function is trivial: \( G_{\alpha\beta}(r, r'; \omega_n) = \delta_{\alpha\beta} G(r, r'; \omega_n) \). Then it follows from Eq. (18) that \( \hat{Y}_{ab}(\omega_n) = \delta_{ab} \hat{Y}(\omega_n) \), therefore \( \hat{d}_0 = (1 - \Gamma \hat{Y})^{-1} \eta \) and \( \hat{d} = 0 \).
The next step is to find the spectrum of the operators \( \hat{Y}_{ab}(\omega_n) \). The orbital effect of the magnetic field is described by a phase factor in the average electron Green’s function: 
\[
\hat{G}(r, r'; \omega_n) = \hat{G}_0(r - r'; \omega_n) e^{i\phi(r, r')},
\]
where \( \hat{G}_0 \) is the average Green’s function in the normal state at zero field, \( \phi(r, r') = (e/c) \int_{r'}^{r} A(r)dr \), and the integration is performed along a straight line connecting \( r \) and \( r' \) (Ref. [25]). The “phase-only” approximation is legitimate if the temperature is not very low, so that the Landau level quantization can be neglected. Using the identity 
\[
e^{2i\phi(r, r')} \eta(r') = e^{-i(r-r')D} \eta(r),
\]
where \( D = -i \nabla + (2e/c)A \), we obtain:
\[
\hat{Y}_{ab}(\omega_n) = \hat{Y}_{ab}(q, \omega_n)|_{q \to D},
\]
where
\[
\hat{Y}_{ab}(q, \omega_n) = \frac{1}{2\pi N_F} \int \frac{d^3k}{(2\pi)^3} \text{tr} \hat{g}_a \hat{G}_0(k + q, \omega_n) \hat{g}_b \hat{G}_0^T(-k, -\omega_n),
\]
Substituting here the Green’s functions (10) and calculating the spin traces, we obtain for the singlet-singlet term:
\[
\hat{Y}_{00}(q, \omega_n) = \frac{1}{2} \sum_{\lambda} \rho_{\lambda} \left( \frac{1}{|\omega_n| + \Gamma + i\nu_{\lambda}(k)q \text{sign} \omega_n/2} \right)_{\lambda},
\]
where
\[
\rho_{\pm} = \frac{N_{\pm}}{N_F} = 1 \pm \delta
\]
are the fractional densities of states in the two bands, and \( \langle (\ldots) \rangle_{\lambda} \) denotes the Fermi-surface averaging in the \( \lambda \)-th band. Similarly, for the singlet-triplet mixing terms we obtain:
\[
\hat{Y}_{0i}(q, \omega_n) = \hat{Y}_{i0}(q, \omega_n) = \frac{1}{2} \sum_{\lambda} \rho_{\lambda} \left( \frac{\hat{\gamma}_i(k)}{|\omega_n| + \Gamma + i\nu_{\lambda}(k)q \text{sign} \omega_n/2} \right)_{\lambda},
\]
We see that the mixing occurs due to the SO coupling and vanishes at \( \gamma \to 0 \), when \( \rho_{+} = \rho_{-} = 1 \) and \( \nu_{+} = \nu_{-} = \nu_F \).
Finally, the triplet-triplet terms can be represented as follows:
\[
\hat{Y}_{ij}(q, \omega_n) = \hat{Y}^{(1)}_{ij}(q, \omega_n) + \hat{Y}^{(2)}_{ij}(q, \omega_n),
\]
where
\[
\hat{Y}^{(1)}_{ij}(q, \omega_n) = \frac{1}{2} \sum_{\lambda} \rho_{\lambda} \left( \frac{\hat{\gamma}_i(k)\hat{\gamma}_j(k)}{|\omega_n| + \Gamma + i\nu_{\lambda}(k)q \text{sign} \omega_n/2} \right)_{\lambda},
\]
and
\[
\hat{Y}^{(2)}_{ij}(q, \omega_n) = \frac{1}{2\pi N_F} \sum_{\lambda} \int \frac{d^3k}{(2\pi)^3} \langle \delta_{ij} - \hat{\gamma}_i \hat{\gamma}_j - i\lambda \epsilon_{ijl} \hat{\gamma}_l \rangle G_{\lambda}(k + q, \omega_n)G_{-\lambda}(-k, -\omega_n).
\]
The singlet impurity scattering channel, which is described by the first term in expression (15), causes only the scattering of intraband pairs between the bands. In contrast, the triplet impurity scattering can create also interband pairs, which are described by \( \hat{Y}^{(2)}_{ij} \). It is easy to show that if the SO band splitting exceeds both \( \omega_c \) and \( \Gamma \), then the second (interband) term in Eq. (25) is smaller than the first (intraband) one, see Appendix A. Note that in real materials, \( E_{SO} \) ranges from tens to hundreds meV, see Ref. [26] for CePt3Si, and Ref. [27] for Li2Pd3B and Li2Pt3B. On the other hand, there is still considerable uncertainty as to the values of \( \omega_c \), especially in heavy-fermion compounds, such as CePt3Si. The typical energy of phonons responsible for the pairing in Li2Pd3B was estimated in Ref. [27] to be 20 meV, while the SO band splitting is 30 meV (reaching 200 meV in Li2Pt3B).

The critical temperature of the phase transition into a uniform superconducting state at zero field can be found by setting \( q = 0 \) in the above expressions. According to Eq. (24), the singlet and triplet channels are decoupled. Then it follows from Eqs. (22) and (17) that \( d_0(\omega_n) = (1 + \Gamma/|\omega_n|)\eta \). Substituting this into Eq. (19), we obtain:
\[
\frac{1}{N_F V} - \pi T \sum_n \frac{1}{|\omega_n|} = 0,
\]
which yields the superconducting critical temperature:

\[ T_{c0} = \frac{2eC}{\pi \omega_c e^{-1/N_F V}}, \]

(29)

where \( C \approx 0.577 \) is Euler’s constant. We see that there is an analog of Anderson’s theorem in noncentrosymmetric superconductors with a BCS-contact pairing interaction: The zero-field critical temperature is not affected by scalar disorder.\(^19\)

In the presence of magnetic field, neglecting the interband contributions to the triplet pair propagator, we obtain:

\[ \hat{\mathcal{Y}}_{ab}(q, \omega_n) = \frac{1}{2} \sum_{\lambda} \rho_\lambda \left\langle \frac{\Lambda_{\lambda, a}(k)\Lambda_{\lambda, b}(k)}{|\omega_n| + \Gamma + i\nu(k)q \sign \omega_n/2} \right\rangle_{\lambda}, \]

(30)

where

\[ \Lambda_{\lambda, a}(k) = \begin{cases} 1, & a = 0 \\ \lambda \hat{\gamma}_a(k), & a = 1, 2, 3 \end{cases}. \]

(31)

Next we use in Eq. \((30)\) the identity \( x^{-1} = \int_0^\infty du e^{-ux} \), and make the substitution \( q \to D \), see Eq. \((20)\), in the exponent to represent \( \hat{\mathcal{Y}}_{ab}(\omega_n) \) as a differential operator of infinite order:

\[ \hat{\mathcal{Y}}_{ab}(\omega_n) = \frac{1}{2} \int_0^\infty du e^{-u(|\omega_n| + \Gamma)} \sum_{\lambda} \rho_\lambda \hat{\mathcal{O}}_{\lambda}^{ab}, \]

(32)

where

\[ \hat{\mathcal{O}}_{\lambda}^{ab} = \left\langle \Lambda_{\lambda, a}(k)\Lambda_{\lambda, b}(k)e^{-iu\nu(k)D \sign \omega_n/2} \right\rangle_{\lambda}. \]

(33)

In order to solve Eqs. \((17)\), with the operators \( \hat{\mathcal{Y}}_{ab}(\omega_n) \) given by expressions \((32)\), we follow the procedure described in Ref. \(17\). We choose the \( z \)-axis along the external field, so that \( H = H \hat{z} \), and introduce the operators

\[ a_\pm = \ell_H \frac{D_x \pm iD_y}{2}, \quad a_3 = \ell_H D_z, \]

(34)

where \( \ell_H = \sqrt{c/eH} \) is the magnetic length. It is easy to check that \( a_+ = a_+^\dagger \) and \( [a_-, a_+] = 1 \), therefore \( a_\pm \) have the meaning of the raising and lowering operators, while \( a_3 = a_3^\dagger \) commutes with both of them: \( [a_3, a_\pm] = 0 \). It is convenient to expand both the order parameter \( \eta \) and the impurity-renormalized gap functions \( d_{n} \) in the basis of Landau levels \( |N, p\rangle \), which satisfy

\[ a_+ |N, p\rangle = \sqrt{N + 1} |N + 1, p\rangle, \quad a_- |N, p\rangle = \sqrt{N} |N - 1, p\rangle, \quad a_3 |N, p\rangle = p |N, p\rangle, \]

(35)

where \( N = 0, 1, \ldots, \) and \( p \) is a real number. We have

\[ \eta(r) = \sum_{N,p} \eta_{N,p} |N, p\rangle \langle N, p|, \quad d_{n}(r, \omega_n) = \sum_{N,p} d_{N,p}^{n}(\omega_n) |N, p\rangle \langle N, p|. \]

(36)

According to Eqs. \((17)\), the expansion coefficients satisfy the following algebraic equations:

\[ \sum_{N'p',b} \left[ \delta_{ab} \delta_{NN'} \delta_{pp'} - \Gamma(N, p) \hat{\mathcal{Y}}_{ab}(\omega_n) |N', p'\rangle \right] d_{N', p'}^{b}(\omega_n) = \delta_{ab} \eta_{N, p}. \]

(37)

Substituting the solutions of these equations into

\[ \frac{1}{N_F V} \eta_{N, p} - \pi T \sum_{n} \frac{d_{N,p}^{n}(\omega_n) - \eta_{N, p}}{\Gamma} = 0, \]

(38)

see Eq. \((19)\), and setting the determinant of the resulting linear equations for \( \eta_{N, p} \) to zero, one arrives at an equation for the upper critical field.
III. CUBIC CASE

In the general case, i.e. for arbitrary crystal symmetry and electronic band structure, the procedure outlined in the previous section does not yield an equation for $H_{cd}(T)$ in a closed form, since all the Landau levels are coupled, and one has to diagonalize infinite matrices. In order to make progress, we focus on the case of a noncentrosymmetric cubic superconductor with the point group $G = O$, which describes, for instance, the crystal symmetry of Li$_2$(Pd$_{1-x}$Pt$_x$)$_3$B. The simplest expression for the SO coupling compatible with all symmetry requirements has the following form:

$$\gamma(k) = \gamma_0 k,$$

where $\gamma_0$ is a constant. We assume a parabolic band: $\epsilon_0(k) = k^2/2m^* - \epsilon_F$, where $m^*$ is the effective mass, $\epsilon_F = k_0^2/2m^*$, and $k_0$ is the Fermi wave vector in the absence of the SO coupling. The band dispersion functions are given by

$$\xi_{\lambda}(k) = \frac{k^2 - k_0^2}{2m^*} + \lambda |\gamma_0| k,$$

so that the SO band splitting is isotropic and given by $E_{SO} = 2|\gamma_0|k_0$. It is convenient to characterize the SO coupling strength by a dimensionless parameter $\varrho = E_{SO}/4\epsilon_F$. While the two Fermi surfaces have different radii: $k_{F,\lambda} = k_0(\sqrt{1 + \varrho^2 - \lambda^2})$, the Fermi velocities are the same: $v_\lambda(k) = v_F k$, where $v_F = k_0 \sqrt{1 + \varrho^2/m^*}$. For the parameter $\delta$, which characterizes the difference between the band densities of states, see Eq. 39, we have $|\delta| = 2\varrho \sqrt{1 + \varrho^2/(1 + 2\varrho^2)}$. We assume that

$$\delta_c \ll |\delta| \leq 1,$$

where $\delta_c = \text{max}(\omega_\lambda, \Gamma)/\epsilon_F \ll 1$. While the first inequality is equivalent to the condition $E_{SO} \gg \text{max}(\omega_\lambda, \Gamma)$, which ensures the smallness of the interband contribution to the Cooper impurity ladder (see Appendix A), the second one is always satisfied, with $|\delta| \to 1$ corresponding to the rather unrealistic limit of extremely strong SO coupling, $\varrho \to \infty$.

In order to solve the gap equations, we make a change of variables in the triplet component:

$$d_\pm(r, \omega_n) = d_1(r, \omega_n) \pm id_2(r, \omega_n).$$

Then, Eqs. (17) take the following form:

$$\begin{pmatrix}
1 - \Gamma \hat{Y}_{00} & -\Gamma \hat{Y}_{03} & -\Gamma \hat{Y}_{0-} & -\Gamma \hat{Y}_{0+} \\
-\Gamma \hat{Y}_{03} & 1 - \Gamma \hat{Y}_{03} & -\Gamma \hat{Y}_{3-} & -\Gamma \hat{Y}_{3+} \\
-\Gamma \hat{Y}_{0-} & -\Gamma \hat{Y}_{3+} & 1 - \Gamma \hat{Z} & -\Gamma \hat{Z}_+ \\
-\Gamma \hat{Y}_{0+} & -\Gamma \hat{Y}_{3-} & -\Gamma \hat{Z}_- & 1 - \Gamma \hat{Z} \\
\end{pmatrix}
\begin{pmatrix}
d_0 \\
d_1 \\
d_2 \\
d_3 \\
\end{pmatrix}
= \begin{pmatrix}
\eta \\
0 \\
0 \\
0 \\
\end{pmatrix},$$

where

$$\hat{Y}_{0\pm} = \frac{\hat{Y}_{01} \pm i\hat{Y}_{02}}{\sqrt{2}}, \quad \hat{Y}_{3\pm} = \frac{\hat{Y}_{13} \pm i\hat{Y}_{23}}{\sqrt{2}}, \quad \hat{Z} = \frac{\hat{Y}_{11} + \hat{Y}_{22}}{2}, \quad \hat{Z}_\pm = \frac{\hat{Y}_{11} \pm 2i\hat{Y}_{12} - \hat{Y}_{22}}{2},$$

with $\hat{Y}_{ab} = \hat{Y}_{ba}$ given by Eqs. (32).

According to Sec. II, one has to know the matrix elements of the operators $\hat{Y}_{ab}(\omega_n)$ in the basis of the Landau levels $|N, p\rangle$. After some straightforward algebra, see Appendix A we obtain the following expressions for the nonzero matrix elements:

$$\langle N, p|\hat{Y}_{00}(\omega_n)|N, p\rangle = y_{00}^{N, p}(\omega_n),$$
$$\langle N, p|\hat{Y}_{03}(\omega_n)|N, p\rangle = y_{03}^{N, p}(\omega_n),$$
$$\langle N, p|\hat{Y}_{0-}(\omega_n)|N, p\rangle = y_{0-}^{N, p}(\omega_n),$$
$$\langle N, p|\hat{Y}_{13}(\omega_n)|N, p\rangle = y_{33}^{N, p}(\omega_n),$$
$$\langle N, p|\hat{Z}(\omega_n)|N, p\rangle = z_{N, p}(\omega_n).$$
where

\[ y_{N,p}^{00}(\omega_n) = \int_0^\infty du \, e^{-u|\omega_n|+\Gamma} \int_0^1 ds \, \cos(pus)e^{-v^2(1-s^2)/2}L_N[v^2(1-s^2)], \]  

\[ y_{N,p}^{03}(\omega_n) = -i\delta \int_0^\infty du \, e^{-u|\omega_n|+\Gamma} \int_0^1 ds \, s \sin(pus)e^{-v^2(1-s^2)/2}L_N[v^2(1-s^2)], \]  

\[ y_{N,p}^{33}(\omega_n) = \int_0^\infty du \, e^{-u|\omega_n|+\Gamma} \int_0^1 ds \, s^2 \cos(pus)e^{-v^2(1-s^2)/2}L_N[v^2(1-s^2)], \]  

\[ z_{N,p}(\omega_n) = \frac{1}{2} \int_0^\infty du \, e^{-u|\omega_n|+\Gamma} \int_0^1 ds \, (1-s^2) \cos(pus)e^{-v^2(1-s^2)/2}L_N[v^2(1-s^2)], \]

\[ v = (v_F \text{ sign } \omega_n/2\ell_H)u, \text{ and } L_N(x) \text{ are the Laguerre polynomials of degree } N. \] Similarly, we obtain:

\[ (N, p|\tilde{\mathcal{J}}_0-(\omega_n)|N + 1, p) = (N + 1, p|\tilde{\mathcal{J}}_0+(\omega_n)|N, p) = \tilde{y}_{N,p}^0(\omega_n), \]

\[ (N, p|\tilde{\mathcal{J}}_3-(\omega_n)|N + 1, p) = (N + 1, p|\tilde{\mathcal{J}}_3+(\omega_n)|N, p) = \tilde{y}_{N,p}^3(\omega_n), \]

\[ (N, p|\tilde{\mathcal{Z}}-(\omega_n)|N + 2, p) = (N + 2, p|\tilde{\mathcal{Z}}+(\omega_n)|N, p) = \tilde{z}_{N,p}(\omega_n), \]

and \( L^{(\ell)}(x) \) are the generalized Laguerre polynomials.

It follows from the above expressions that the Landau levels are decoupled, and for \( \eta(r) = \eta(r|N, p) \) (\( \eta \) is a constant) the solution of Eqs. \ref{eq:42} has the following form:

\[ \begin{pmatrix} d_0(r, \omega_n) \\ d_3(r, \omega_n) \\ d^+_1(r, \omega_n) \\ d^-_1(r, \omega_n) \end{pmatrix} = \begin{pmatrix} d_{N,p}^0(\omega_n)(r|N, p) \\ d_{N,p}^3(\omega_n)(r|N, p) \\ d_{N,p}^1(\omega_n)(r|N + 1, p) \\ d_{N,p}^-_1(\omega_n)(r|N - 1, p) \end{pmatrix}. \]  

For given \( N \) and \( p \), the coefficients are found from the equations

\[ \sum_{b=0,3,\pm} \mathcal{M}_{ab}(N, p; \omega_n)d_{N,p}^b(\omega_n) = \delta_{a0}\eta, \]  

where

\[ \hat{\mathcal{M}}(N, p; \omega_n) = \begin{pmatrix} 1 - \Gamma y_{N,p}^{00} & \Gamma y_{N,p}^{03} & \Gamma y_{N,p}^0 & \Gamma y_{N,p}^{01} \\ \Gamma y_{N,p}^{03} & 1 - \Gamma y_{N,p}^{33} & \Gamma y_{N,p}^{31} & \Gamma y_{N,p}^{31} \\ \Gamma y_{N,p}^0 & \Gamma y_{N,p}^{31} & 1 - \Gamma y_{N,p}^{11} & \Gamma y_{N,p}^{11} \\ \Gamma y_{N,p}^{01} & \Gamma y_{N,p}^{31} & \Gamma y_{N,p}^{11} & 1 - \Gamma y_{N,p}^{11} \end{pmatrix}. \]  

Substituting the solution of Eq. \ref{eq:51} in Eq. \ref{eq:38}, and using Eqs. \ref{eq:28} and \ref{eq:29} to eliminate both the frequency cutoff and the coupling constant, we obtain an equation implicitly relating the magnetic field and the transition temperature at given \( N \) and \( p \):

\[ \ln \frac{T_c}{T} = \pi T \sum_n \left\{ \frac{1}{|\omega_n|} - \frac{[\hat{\mathcal{M}}^{-1}(N, p; \omega_n)]_{00} - 1}{\Gamma} \right\}. \]  

The upper critical field, \( H_{c2}(T) \), is obtained by maximizing the solution of this equation with respect to both \( N \) and \( p \).
Note that the matrix elements of $\hat{M}$ which are responsible for the singlet-triplet mixing, i.e. $g_{N-p, p}$ and $g_{N-1, p}$, are all proportional to $\delta$, see Eqs. (44) and (47). Therefore, at $|\delta| \ll 1$ the singlet and triplet channels are effectively decoupled. Neglecting the corrections of the order of $\delta^2$, we obtain from Eq. (51) that $[\hat{M}^{-1}(N, p; \omega_n)]_{00} = (1 - \Gamma y_{N,p})^{-1}$. Substituting this into Eq. (53), we recover the Helfand-Werthamer expressions, with the maximum critical field corresponding to $N = p = 0$ at all temperatures. Thus, in the weak SO coupling limit the absence of inversion symmetry does not bring about any new features in $H_{c2}(T)$, compared with the centrosymmetric case (as long as the paramagnetic pair breaking is not included, see Ref. [21]).

A. “Dirty” limit at $N = 0$, $p = 0$

At arbitrary magnitude of the SO band splitting, the singlet-triplet mixing makes the $H_{c2}$ equation in noncentrosymmetric superconductors considerably more cumbersome than in the Helfand-Werthamer problem, even in our “minimal” isotropic model. It is even possible that, at some values of the parameters, the maximum critical field is achieved for $N > 0$ and $p \neq 0$, the latter corresponding to a disorder-induced modulation of the order parameter along the applied field. Leaving investigation of these exotic possibilities to future work, here we just consider the case $N = p = 0$. Then it follows from Eqs. (50) and (51) that $d_0^2 = 0$, and $[\hat{M}^{-1}(0, 0; \omega_n)]_{00} = (1 - \Gamma z_{1,0})/[(1 - \Gamma y_{0,0})(1 - \Gamma z_{1,0}) - \Gamma^2 (\gamma_{0,0})^2]$. It is convenient to introduce the reduced temperature, magnetic field, and disorder:

$$t = \frac{T}{T_{c0}}, \quad h = \frac{2H}{H_0}, \quad \zeta = \frac{\Gamma}{\pi T_{c0}},$$

where $H_0 = \Phi_0/\pi \xi_0^2$, $\Phi_0 = \pi c/e$ is the magnetic flux quantum, and $\xi_0 = v_F/2\pi T_{c0}$ is the superconducting coherence length. In these notations, Eq. (53) yields the following equation for the upper critical field $h_{c2}(t)$:

$$\ln \frac{1}{t} = 2 \sum_{n \geq 0} \left[ \frac{1}{2n+1} - t \frac{w_n (1 - \zeta p_n) - \zeta \delta^2 q_n^2}{(1 - \zeta w_n)(1 - \zeta p_n) + \zeta^2 \delta^2 q_n^2} \right],$$

(54)

where

$$w_n (t, h) = \int_0^\infty d\rho e^{-\tilde{\omega}_n \rho} \int_0^1 ds e^{-h \rho^2 (1-s^2)/4},$$

$$p_n (t, h) = \int_0^\infty d\rho e^{-\tilde{\omega}_n \rho} \int_0^1 ds \frac{1}{2} \left[ 1 - \frac{h}{2} \rho^2 (1-s^2) \right] e^{-h \rho^2 (1-s^2)/4},$$

$$q_n (t, h) = \int_0^\infty d\rho e^{-\tilde{\omega}_n \rho} \int_0^1 ds \sqrt{\frac{h}{4}} \rho (1-s^2) e^{-h \rho^2 (1-s^2)/4},$$

(55)

where $\tilde{\omega}_n = (2n+1)t + \zeta$.

In the clean limit, i.e. at $\zeta \to 0$, or if the SO band splitting is negligibly small, i.e. at $\delta \to 0$, one recovers from Eq. (54) the Helfand-Werthamer equation for a centrosymmetric superconductor. Thus the absence of inversion symmetry affects the upper critical field only if disorder is present. One can expect that the effect will be most pronounced in the “dirty” limit, $\zeta \gg 1$. [Note that, according to Eq. (11), the disorder strength should satisfy $\zeta \ll (\epsilon_F/T_{c0})|\delta|$.] We shall see that in this limit $h_{c2}$ scales as $\zeta$, which allows one to use the Taylor expansions of the exponentials in Eqs. (55):

$$w_n (t, h) \simeq \frac{1}{\tilde{\omega}_n} \left( 1 - \frac{h}{3\tilde{\omega}_n^2} \right), \quad p_n (t, h) \simeq \frac{1}{3\tilde{\omega}_n} \left( 1 - \frac{6h}{5\tilde{\omega}_n^2} \right), \quad q_n (t, h) \simeq \frac{\sqrt{h}}{3\tilde{\omega}_n^2}.$$

Using the fact that the main contribution to the Matsubara sum in Eq. (54) comes from $(2n+1)t \ll \zeta$, we arrive at a well-known universal equation, which describes the magnetic pair breaking in superconductors:

$$\ln \frac{1}{t} = \Psi \left( \frac{1}{2} + \frac{\sigma}{t} \right) - \Psi \left( \frac{1}{2} \right),$$

(56)

where $\Psi(x)$ is the digamma function, and

$$\sigma = \frac{2 + \delta^2}{12\zeta}.$$
characterizes the pair-breaker strength. Note that the corresponding expression in the centrosymmetric case is different: \( \sigma_{CS} = h/6\zeta \) (Ref. [17]). Analytical expressions for the upper critical field can be obtained in the weak-field limit near the critical temperature:

\[
h_{c2}|_{t\to 1} = \frac{24\zeta}{(2 + \delta^2)\pi^2}(1 - t),
\]

(58)

and also at low temperatures:

\[
h_{c2}|_{t=0} = \frac{3e^{-C}}{2 + \delta^2}\zeta.
\]

(59)

We see that the SO band splitting in the noncentrosymmetric case enhances the orbital pair breaking.

IV. CONCLUSIONS

We have derived equations for the upper critical field in noncentrosymmetric superconductors, assuming a BCS-contact pairing interaction and orbital pair breaking. In a cubic crystal (the point group \( G = O \)), in which both the electron dispersion and the SO coupling are isotropic, the gap equations are shown to be diagonal in the Landau level basis, with the singlet and triplet channels in the pair propagator mixed together. For the order parameter corresponding to the lowest Landau level, without any modulation along the applied field, we have derived the \( H_{c2} \) equation in a closed form and solved it in the “dirty” limit, in which the effects of the absence of inversion symmetry are expected to be most pronounced. The effect on the upper critical field of the singlet-triplet mixing, which is responsible for the deviations from the Helfand-Werthamer theory, is found to be proportional to \( \delta^2 \).

Application of our theory to real noncentrosymmetric superconductors of cubic symmetry, such as \( \text{Li}_2(\text{Pd}_{3-x}\text{Pt}_x)\text{B} \), is complicated by the fact that the Fermi surfaces as well as the SO band splitting are strongly anisotropic. Using the maximum values of the SO band splitting from Ref. [27], one can estimate the corrections to \( H_{c2}(T) \) due to the singlet-triplet mixing to be of the order of several percent.

APPENDIX A: INTERBAND VS INTRABAND CONTRIBUTIONS

In this appendix, we estimate the relative magnitudes of the intraband and interband contributions to the triplet pair propagator, Eq. (25), in the limit when the SO coupling is strong compared with both the cutoff energy \( \omega_c \) and the elastic scattering rate \( \Gamma \). Let us consider an isotropic band with \( \gamma(k) = \gamma_0 k \) in a cubic crystal. Neglecting for simplicity the differences between the densities of states and the Fermi velocities in the two bands: \( \rho_+ = \rho_- = 1 \) and \( v_+ = v_- = v_F \), and setting \( q = 0 \), we obtain from Eqs. (26) and (27):

\[
\bar{\gamma}_{ij}^{(1)}(q=0,\omega_n) = \frac{\langle \hat{\gamma}_i \hat{\gamma}_j \rangle_k}{|\omega_n| + \Gamma} = \frac{\delta_{ij}}{3(|\omega_n| + \Gamma)} \equiv \mathcal{Y}_{\text{intra}}(\omega_n)\delta_{ij},
\]

and

\[
\bar{\gamma}_{ij}^{(2)}(q=0,\omega_n) = \frac{1}{2} \sum_{\lambda} \frac{\delta_{ij} - \hat{\gamma}_i \hat{\gamma}_j}{|\omega_n| + \Gamma + i\lambda|\gamma| \text{sign} \omega_n} \equiv \frac{2\delta_{ij}}{3(|\omega_n| + \Gamma)(1 + r^2)} \equiv \mathcal{Y}_{\text{inter}}(\omega_n)\delta_{ij},
\]

where \( r(\omega_n) = E_{SO}/2(|\omega_n| + \Gamma) \). Due to the BCS cutoff, the maximum value of \( \omega_n \) is equal to \( \omega_c \), therefore \( r_{\text{min}} \sim E_{SO}/\max(\omega_c, \Gamma) \gg 1 \). From this it follows that

\[
\max_n \mathcal{Y}_{\text{inter}}(\omega_n) = \frac{2}{1 + r_{\text{min}}^2} \sim \left[ \max(\omega_c, \Gamma) \frac{E_{SO}}{\max(\omega_c, \Gamma)} \right]^2 \ll 1.
\]

Therefore the interband contribution is small compared with the intraband one, at all Matsubara frequencies.
APPENDIX B: CALCULATION OF $\langle N, p | \hat{Y}_{ab}(\omega_n) | N', p' \rangle$

The operators $\hat{Y}_{ab}(\omega_n)$ are given by expressions (32). For a spherical Fermi surface and $\gamma(k) = \gamma_0 k$, we obtain from Eq. (33):

$$\hat{O}_{\lambda}^{ab} = \frac{1}{2} \int_0^\pi d\theta \sin \theta e^{-i v a_3 \cos \theta} \int_0^{2\pi} \frac{d\phi}{2\pi} \Phi_{\lambda}^{ab}(\theta, \phi) e^{-i v a_i \omega_{a+}^i - i \hat{a}_a} \sin \theta,$$

where $v = (v_F \sin \omega_n / 2 \ell_H) u$, and $\Phi_{\lambda}^{ab}(\theta, \phi) = \Lambda_{\lambda,0}(k) \Lambda_{\lambda,b}(k)$, with $\Lambda_{\lambda,0}(k) = 1$ and $\Lambda_{\lambda,i}(k) = \lambda k_i$ for $i = 1, 2, 3$, see Eq. (31). Using the well-known operator identity $e^{A+B} = e^{-[A,B]/2} e^A e^B$, which holds if the commutator of $A$ and $B$ is a $c$-number, and expanding the exponentials in powers of $a_\pm$, we obtain:

$$\hat{Y}_{ab}(\omega_n) = \frac{1}{4} \sum_\lambda \rho_\lambda \int_0^\infty du e^{-\omega (\omega_n + \Gamma)} \int_0^\pi d\theta \sin \theta e^{-i v a_3 \cos \theta} e^{-(v^2/2) \sin^2 \theta} \hat{L}_{\lambda}^{ab}(\theta),$$

where

$$\hat{L}_{\lambda}^{ab}(\theta) = \sum_{n,m=0}^{\infty} \frac{(-i v \sin \theta)^{n+m}}{n! m!} \left[ \int_0^{2\pi} \frac{d\phi}{2\pi} \Phi_{\lambda}^{ab}(\theta, \phi) e^{i(m-n)\phi} \right] a_+^n a_+^m.$$  (B3)

Below we perform the detailed calculations for $\hat{Y}_{00}$ and $\hat{Y}_{0-} = (\hat{Y}_{01} - i \hat{Y}_{02}) / \sqrt{2}$. Other matrix elements can be considered in a similar fashion.

$\hat{Y}_{00}$: Since $\Phi_{\lambda}^{ab}(\theta, \phi) = 1$, the $\phi$-integral on the right-hand side of Eq. (B3) is equal to $\delta_{nm}$, and

$$\hat{L}_{00}^{00}(\theta) = \sum_{n=0}^{\infty} \frac{(-v^2 \sin^2 \theta)^n}{n!^2} a_+^n a_+^n.$$  (B3)

It is easy to show, using Eqs. (33), that $a_+^n a_+^n | N, p = | N!/(N-n)! | N, p \rangle$ for $n \leq N$, and zero otherwise. Therefore,

$$\hat{L}_{00}^{00}(\theta) | N, p \rangle = \sum_{n=0}^{N} \frac{N!}{(n!)^2 (N-n)!} \frac{(-v^2 \sin^2 \theta)^n}{n!} | N, p \rangle = L_N(v^2 \sin^2 \theta) | N, p \rangle,$$

where $L_N(x)$ is the Laguerre polynomial of degree $N$. Substituting this into Eq. (B2), using the fact that $\rho_+ + \rho_- = 2$, and introducing $s = \cos \theta$, we obtain: $\langle N, p | \hat{Y}_{00}(\omega_n) | N, p \rangle = y_{N,p}^{00}(\omega_n)$, where $y_{N,p}^{00}(\omega_n)$ is given by Eq. (43).

$\hat{Y}_{0-}$: Since $\Phi_{\lambda}^{0-}(\theta, \phi) = \lambda \sin \theta e^{-i \phi} / \sqrt{2}$, one has $m = n + 1$ on the right-hand side of Eq. (B3), and

$$\hat{L}_{0-}^{0-}(\theta) = \lambda \sin \theta \frac{\sqrt{2}}{2} \sum_{n=0}^{\infty} \frac{(-i v \sin \theta)^{2n+1}}{n!(n+1)!} a_+^n a_-^{n+1}.$$  (B3)

Using $a_+^n a_+^{n+1} | N+1, p \rangle = \sqrt{N+1} | N!/(N-n)! | N, p \rangle$ (if $n \leq N$, zero otherwise), we obtain:

$$\hat{L}_{0-}^{0-}(\theta) | N+1, p \rangle = \frac{-i \lambda v \sin^2 \theta}{\sqrt{2}} \sum_{n=0}^{N} \frac{N!}{(N-n)!} \frac{(-v^2 \sin^2 \theta)^n}{n!(n+1)!} | N, p \rangle = \frac{-i \lambda}{\sqrt{2(N+1)}} v \sin^2 \theta \hat{L}_{N}^{(1)}(v^2 \sin^2 \theta) | N, p \rangle,$$

where $L_N^{(1)}(x)$ are the generalized Laguerre polynomials:

$$L_N^{(1)}(x) = \sum_{n=0}^{N} \frac{(N+\alpha)!}{(N-n)! n! (n+\alpha)!} (-x)^n,$$

see Ref. 23 (the Laguerre polynomials are recovered by setting $\alpha = 0$). Substituting this into Eq. (B2) and using $\rho_+ - \rho_- = 2 \delta$, we obtain: $\langle N, p | \hat{Y}_{0-}(\omega_n) | N+1, p \rangle = y_{N,p}^0(\omega_n)$, where $y_{N,p}^0(\omega_n)$ is given by Eq. (47).
