(Dated: January 25, 2022)

Under the Born-Oppenheimer approximation, the electronic ground state evolves adiabatically and can accumulate nontrivial geometrical phases characterized by the molecular Berry curvature. In this work, we study the effect of the molecular Berry curvature on the lattice dynamics in a system with broken time-reversal symmetry. The molecular Berry curvature is formulated based on the single-particle electronic Bloch states. It manifests as a non-local effective magnetic field in the equations of motion of the ions that are beyond the widely adopted Raman spin-lattice coupling model. We employ the Bogoliubov transformation to solve the quantized equations of motion and to obtain phonon polarization vectors. We apply our formula to the Haldane model on a honeycomb lattice and find a large molecular Berry curvature around the Brillouin zone center. As a result, the degeneracy of the optical branches at this point is lifted intrinsically. The lifted optical phonons show circular polarizations, possess large phonon Berry curvature, and have a nearly quantized angular momentum that modifies the Einstein-de Haas effect.

I. INTRODUCTION

The Born-Oppenheimer approximation assumes an adiabatic evolution of electronic states following motion of the ions. During the evolution, the electronic ground state can accumulate nontrivial geometrical phase in the absence of time-reversal symmetry. The influence of this phase on the ion’s dynamics was discussed first by Mead and Truhlar in molecules, which was later identified as an electronic Berry phase with respect to the ion’s displacement and dubbed as a molecular Berry phase. In magnetic molecules, the molecular Berry phase can induce vibration modes with nonzero angular momentum.

In a periodic lattice, the molecular Berry curvature associated with this phase can influence directly the lattice dynamics and therefore the properties of the phonons. In the long-wavelength limit, this Berry curvature manifests as a Hall viscosity that can modify the dispersion, polarization, and transport properties of the long-wavelength phonons. By considering a finite overlap between electronic wavefunctions on neighboring sites, a recent work studied the molecular Berry curvature induced by a magnetic field in a nonmagnetic insulator in the linear order of . However, the molecular Berry curvature in a Bloch system without a uniform magnetic field has not been explicitly studied. A Bloch-wavefunction-based formula of the molecular Berry curvature is highly desired.

In this work, we explore the effect of molecular Berry curvature on the lattice dynamics in the absence of a uniform magnetic field. In an electronic system that breaks the time-reversal symmetry and respects the translational symmetry we formulate the molecular Berry curvature by using single-particle Bloch wavefunctions and assuming the many-body electronic ground state as a Slater determinant. The molecular Berry curvature influences the lattice dynamics as an effective magnetic field, which however is nonlocal. We then employ the Bogoliubov transformation to solve the quantized equation of motions and to obtain the spectrum and polarization vector of the phonons.

We apply the formula to the Haldane model of a honeycomb lattice. The molecular Berry curvature exhibits a peak value at the Brillouin zone center. The peak value depends strongly on the electronic band gap and the electronic band topology. The narrow distribution of the molecular Berry curvature in momentum space indicates that, in real space, one atom can be influenced by the velocity of another atom far away. With the molecular Berry curvature, the double degeneracy of the optical phonons at the Brillouin zone center is lifted intrinsically, in contrast to the splitting induced extrinsically by the magnetic field. The polarization vectors become left and right-handed, separately, which carry nonzero angular momenta contributing to a nonzero zero-point angular momentum of the lattice vibration. The phonon modes also carry nonzero phonon Berry curvature and contribute to the phonon thermal Hall effect, which attracts much attention in experiments recently.

II. MOLECULAR BERRY CURVATURE AND PHONON POLARIZATION

A. Molecular Berry curvature

Under the Born-Oppenheimer approximation, electrons stay at their instantaneous ground state at a given time with lattice configuration . When the lattice configuration evolves, the electronic ground state evolves adiabatically and accumulates a geometrical phase, which in turn can modify the lattice dynamics. The geometrical phase manifests itself as a gauge field in the lattice Hamiltonian (it was originally re-
ported by Mead and Truhlar and an alternative derivation is shown in Appendix A)

\[ H_L = \sum_{l,\kappa} \frac{1}{2M_{\kappa}} \left( p_{l,\kappa} - \hbar A_{l,\kappa} \{ \mathbf{R} \} \right)^2 + V_{\text{eff}}(\{ \mathbf{R} \}) \]  

(1)

where \( p_{l,\kappa} = -i\hbar \nabla_{l,\kappa} \) with \( \nabla_{l,\kappa} = \partial / \partial \mathbf{R}_{l,\kappa} \) is the canonical momentum of the \( \kappa \)-th atom at the \( l \)-th unit cell with a coordinate \( \mathbf{R}_{l,\kappa} \) and a mass \( M_{\kappa} \). The scalar potential \( V_{\text{eff}}(\{ \mathbf{R} \}) \) is contributed from the Coulomb interaction of the ions and the electrons whereas the vector potential \( A_{l,\kappa} = i\langle \mathbf{0} \{ \mathbf{R} \} [\nabla_{l,\kappa} \Phi_0(\{ \mathbf{R} \})] \rangle \) is the molecular Berry connection that describes the geometrical phase of the electronic ground state. Although the molecular Berry connection is gauge dependent, it can give rise to a gauge invariant molecular Berry curvature.

\[ G_{\kappa\alpha\beta}(\mathbf{R}_l, \mathbf{R}_{l'}) = 2\text{Im} \left( \frac{\partial \Phi_0}{\partial \mathbf{R}_{l',\kappa'}} \frac{\partial \Phi_0}{\partial \mathbf{R}_{l,\kappa}} \right) \]  

(2)

where the indices \( \alpha, \beta \) represent the Cartesian components of the coordinates. One can proceed further under the assumption that every lattice point vibrates around its equilibrium position with \( \{ \mathbf{R} \} = \{ \mathbf{R}_{0}^\kappa + u_{l,\kappa} \} \) where the equilibrium position \( \mathbf{R}_{0}^\kappa \equiv \mathbf{R}_{0}^\kappa + \mathbf{d}_\kappa \) with \( \mathbf{R}_{0}^\kappa \) being the equilibrium position of the \( l \)-th unit cell, \( \mathbf{d}_\kappa \) being the relative position of the \( \kappa \)-th ion, and \( u_{l,\kappa} \) being its displacement. At the equilibrium configuration, the Berry curvature \( G_{\kappa\alpha\beta}(\mathbf{R}_l, \mathbf{R}_{l'}) \) exhibits translational symmetry that depends on \( \mathbf{R}_l^\kappa - \mathbf{R}_{l'}^\kappa \) only.

In the following, we consider a symmetric gauge which exists near the equilibrium position as shown in Appendix B, such that

\[ A_{l,\kappa\alpha} = -\frac{1}{2} \sum_{\kappa',\beta, \ell} G_{\kappa'\alpha\beta}(\mathbf{R}_l^\kappa - \mathbf{R}_{l'}^\kappa) u_{\ell,\kappa'} \beta \]  

(3)

By taking the advantage of the translational invariance, we express the lattice Hamiltonian in momentum space

\[ H_L = \sum_{\kappa, l} \frac{1}{2M_{\kappa}} \left[ p_{\kappa}(k) - \hbar A_{\kappa}(k) \right] \left[ p_{\kappa}(-k) - \hbar A_{\kappa}(-k) \right] + V_{\text{eff}}(\{ \mathbf{u}(k) \}) \]  

(4)

where the momentum-space Berry connection

\[ A_{\kappa\alpha}(k) = \frac{1}{\sqrt{N}} \sum_{l} A_{l,\kappa\alpha} e^{-i \mathbf{k} \cdot \mathbf{R}_l^\kappa} = -\frac{1}{2} \sum_{\kappa', \beta} G_{\kappa'\alpha\beta}(k) u_{\kappa'} \beta(k) \]  

with

\[ u_{\kappa}(k) = \frac{1}{\sqrt{N}} \sum_{l} u_{l,\kappa} e^{-i \mathbf{k} \cdot \mathbf{R}_l^\kappa} \]

\[ p_{\kappa}(k) = \frac{1}{\sqrt{N}} \sum_{l} p_{l,\kappa} e^{-i \mathbf{k} \cdot \mathbf{R}_l^\kappa} \]  

\[ G_{\kappa'\alpha\beta}(k) = \frac{1}{N} \sum_{l} \sum_{l'} G_{\kappa'\alpha\beta}(\mathbf{R}_l^\kappa - \mathbf{R}_{l'}^\kappa) e^{-i \mathbf{k} \cdot (\mathbf{R}_l^\kappa - \mathbf{R}_{l'}^\kappa)} \]  

(5)

We further express the momentum-space molecular Berry curvature in a gauge invariant form by employing a set of many-body wavefunction \( \{ \Phi_n \} \) with the completeness relation \( \sum_n \langle \Phi_n | \Phi_n \rangle = 1 \) and associated eigenenergy \( E_n \). By using the identity \( \langle \Phi_n | \mathcal{M}_{k,\kappa,\alpha} | \Phi_{n'} \rangle = \langle \Phi_{n'} | \mathcal{M}_{k,\kappa,\alpha} | \Phi_n \rangle (E_n - E_{n'}) \) for \( n' \neq n \), the molecular Berry curvature reads

\[ G^{\alpha\beta}_{\kappa'}(k) = i \sum_n \frac{\langle \Phi_n | \mathcal{M}_{k,\kappa,\alpha} | \Phi_n \rangle \langle \Phi_n | \mathcal{M}_{-k,\kappa',\beta} | \Phi_0 \rangle}{(E_n - E_0)^2} \]  

\[ - \{ \mathcal{M}_{k,\kappa,\alpha} \leftrightarrow \mathcal{M}_{-k,\kappa',\beta} \} \]  

(6)

where \( E_0 \) is the energy of the electronic ground state, \( E_n \) is for the excited states, \( \mathcal{M}_{k,\kappa,\alpha} = \frac{\partial \Phi_n}{\partial u_{\kappa,\alpha}} \) represents the electron-phonon coupling with \( H_e \) being the electronic Hamiltonian that depends on the atomic coordinates. By further taking \( \{ \Phi_n \} \) as Slater determinant, the above formula can be expressed in terms of single-particle Bloch wavefunctions as detailed in Appendix D. This expression can readily be applied to a specific model using the first-principles approach.

B. Phonon Polarization Vectors

We further simplify the notation by normalizing the coordinates and expressing the Hamiltonian in terms of matrices. We first define column vectors \( \mathbf{p}_k = \left( \ldots p_{\kappa\alpha}(k) / \sqrt{M_{\kappa}} \ldots \right)^T \) and \( \mathbf{u}_k = \left( \ldots \sqrt{M_{\kappa}} u_{\kappa\alpha}(k) \ldots \right)^T \). For the two dimensional system studied in this work, there are 2\( \nu \) elements. We also define the matrix \( \tilde{G}_k \) with elements \( \tilde{G}_{k}^{\nu\gamma}(k) \) (see Appendix E). By expressing the potential energy in a quadratic form \( V_{\text{eff}}(\{ \mathbf{u}(k) \}) = \frac{1}{2} \mathbf{u}_k^\dagger K_k \mathbf{u}_k \), the lattice Hamiltonian reads

\[ H_L = \sum_k \frac{1}{2} \begin{pmatrix} \mathbf{u}_k \\ \mathbf{p}_k \end{pmatrix} \begin{pmatrix} D_k & \tilde{G}_k \\ \tilde{G}_k^\dagger & \frac{1}{2} \end{pmatrix} \begin{pmatrix} \mathbf{u}_k \\ \mathbf{p}_k \end{pmatrix} \]  

(7)

where \( D_k = K_k + \tilde{G}_k^\dagger \tilde{G}_k \). It is noted that \( D_k \) here is different from that in Ref. The corresponding canonical equations of motion are

\[ \left( \begin{pmatrix} \dot{\mathbf{u}}_k \\ \dot{\mathbf{p}}_k \end{pmatrix} \right) = \left( \begin{pmatrix} \partial H_L / \partial u_{\kappa\alpha} \\ -\partial H_L / \partial p_{\kappa\alpha} \end{pmatrix} \right) = \begin{pmatrix} \tilde{G}_k & \frac{1}{2} \\ -D_k & \tilde{G}_k \end{pmatrix} \begin{pmatrix} \mathbf{u}_k \\ \mathbf{p}_k \end{pmatrix} \]  

(8)

We then introduce the canonical transformation

\[ \mathbf{u}_k = \sum_{\nu} \sqrt{\frac{\hbar}{\omega_{\kappa\nu}}} \left( \gamma_{\kappa\nu}^b b_{\kappa,\nu} + \gamma_{\nu,\kappa}^b b_{\kappa,\nu} \right) \]  

(9)

\[ \mathbf{p}_k = \sum_{\nu} i \sqrt{\frac{\hbar}{\omega_{\kappa\nu}}} \left( \tilde{\gamma}_{\kappa\nu}^b b_{\kappa,\nu}^\dagger - \tilde{\gamma}_{\nu,\kappa}^b b_{\kappa,\nu} \right) \]  

(10)
to diagonalize the Hamiltonian as

$$H_L = \sum_{k,\nu} \hbar \omega_{k,\nu} \left( b_{k,\nu}^{\dagger} b_{k,\nu} + \frac{1}{2} \right)$$  \hspace{1cm} (11)$$

where $b_{k,\nu}^{\dagger}$ and $b_{k,\nu}$ are the creation and annihilation operators of the phonon modes. These operators are constrained by the commutation relation $[b_{k,\nu}, b_{k',\nu'}^{\dagger}] = \delta_{k,k'} \delta_{\nu,\nu'}$ and the Heisenberg equations of motion

$$\dot{b}_{k,\nu} = -i \omega_{k,\nu} b_{k,\nu} \quad \dot{b}_{-k,\nu}^{\dagger} = i \omega_{-k,\nu} b_{-k,\nu}^{\dagger}. \hspace{1cm} (12)$$

Assisted by these identities, the phonon energy $\omega_{k,\nu}$ and the polarization vector $\psi_{\nu} = (\gamma_{\nu}, \gamma_{\nu})^T$ need to satisfy the eigenvalue equation

$$\omega_{k,\nu} \psi_{\nu} = \left( i \vec{G}_k \omega_0 \right)^T \psi_{\nu} \hspace{1cm} (13)$$

which can be obtained by substituting Eqs. (9) and (10) into Eq. (5). The eigenvalues show particle-hole symmetry like property, i.e., $\omega_{\nu_k, k} = -\omega_{-\nu_k, -k}$. Only the positive branches are physically allowed since only the wavefunctions for those branches can make the commutation relation $[b_{k,\nu}, b_{k',\nu'}^{\dagger}] = \delta_{k,k'} \delta_{\nu,\nu'}$ valid with the normalization condition $\langle \psi_{\nu} | \psi_{\nu} \rangle = 1$.

One can transform the non-Hermitian problem to a Hermitian one. By multiplying Eq. (13) with $\sigma_x$ from left, one can find that

$$\omega_{k,\nu} \sigma_x \psi_{\nu} = \Omega_k \psi_{\nu} \hspace{1cm} (14)$$

with the Hermitian matrix

$$\Omega_k = \left( \begin{array}{cc} \frac{D_k}{i \vec{G}_k} & -i \vec{G}_k^0 \\ i \vec{G}_k^0 & \omega_0 \end{array} \right).$$

Multiplying Eq. (14) with $\Omega_k^{-1} \sigma_x$ from left side and introducing a new set of eigenstates $\tilde{\psi}_{\nu} = \Omega_k \psi_{\nu}$, where $\Omega_k^{-1}$ is also Hermitian, we come to a Hermitian eigenvalue problem as

$$\omega_{k,\nu} \tilde{\psi}_{\nu} = \Omega_k^{1/2} \sigma_x \Omega_k^{1/2} \tilde{\psi}_{\nu} = H_{\text{eff}} \tilde{\psi}_{\nu} \hspace{1cm} (15)$$

where the effective Hamiltonian $H_{\text{eff}}$ is Hermitian.

III. LATTICE DYNAMICS IN HALDANE MODEL

A. Electronic Model and Molecular Berry curvature

In this section, we present a case study on the dynamics of the honeycomb lattice. In the harmonic approximation, the atoms are considered connected by springs with longitudinal and transverse spring constants $K_L$ and $K_T$, respectively. Details of this model can be found in Appendix E.

The time-reversal symmetry is broken by the electronic property described by the Haldane model with a tight-binding Hamiltonian

$$H_e = -\sum_{\langle i,j \rangle} t a_{i}^{\dagger} b_{j} + \text{h.c.} - \sum_{\langle i,j \rangle} t' e^{i \phi_{ij}} a_{i}^{\dagger} a_{j} - \sum_{\langle i,j \rangle} t' e^{-i \phi_{ij}} b_{i}^{\dagger} b_{j} \hspace{1cm} (16)$$

where $a_{i}$ ($a_{i}^{\dagger}$) and $b_{i}$ ($b_{i}^{\dagger}$) are electron creation (annihilation) operators of $A$ and $B$ sublattices respectively in the $i$-th unit cell. The first line represents the nearest neighbor hopping with the hopping energy $t$ while the second line represents the next-nearest neighbor hopping with a flux $\phi_{ij}$ attached to it. We set $\phi_{ij} = \pm \pi/2$ for clockwise/anti-clockwise hoppings. The lattice Hamiltonian can also be expressed in momentum space with kernel $\mathcal{H}(q)$ and $q$ running over the first Brillouin zone. The single-particle Bloch eigenstates for the conduction and valence bands are denoted as $\phi_q^{\sigma,v}$ with corresponding eigen-energies $\varepsilon_q^{\sigma,v}$. The Bloch bands are plotted in Fig. 1a).

The phonons couple to the electronic system through the dependence of the hopping energies $t$ and $t'$ on the lattice displacement $\{u\}$. The nearest-neighbor hopping energy $t$ depends on the relative distance $d$ between the two atoms. When the inter-atomic distance changes by
\[ G_{A_y}^{G}(k) = \frac{i}{N} \sum_{q} \left[ \phi_{q+k,A_x}^\dagger \phi_{q+k}^{A_y} \right] \left( \varepsilon_{q+k} - \varepsilon_q \right)^2 \]

where \( M_{\pm k,A_x/A_y} \) represent the electron-phonon couplings as detailed in Appendix D that couple the electronic states with a momentum difference of \( \Delta k \). In the non-interacting case, the many-body ground state \( |\Phi_0\rangle \) and the excited one \( |\Phi_n\rangle \) can be expressed as the Slater determinant of single-particle states. One thus can calculate the Berry curvature shown in Eq. (15) by using the single-particle states. We can take the Berry curvature induced by the motion of A sublattices along \( x \) and \( y \) directions as an example, which can be expressed as

\[ \delta d \text{ due to atomic displacement, } t \text{ changes by } \partial_d \delta d. \] Here we set \( t' \) as a constant for simplicity.

In this work, we consider the electronic insulating system with the lower Bloch band being completely filled. In the non-interacting case, the many-body ground state \( |\Phi_0\rangle \) and the excited one \( |\Phi_n\rangle \) can be expressed as the Slater determinant of single-particle states. One thus can calculate the Berry curvature shown in Eq. (15) by using the single-particle states. We can take the Berry curvature induced by the motion of A sublattices along \( x \) and \( y \) directions as an example, which can be expressed as

\[ G_{A_y}^{G}(k) = \frac{i}{N} \sum_{q} \left[ \phi_{q+k,A_x}^\dagger \phi_{q+k}^{A_y} \right] \left( \varepsilon_{q+k} - \varepsilon_q \right)^2 \]

where \( M_{\pm k,A_x/A_y} \) represent the electron-phonon couplings as detailed in Appendix D that couple the electronic states with a momentum difference of \( \Delta k \). In Fig. 1(b), we plot the contribution from each electronic momentum \( q \) to the molecular Berry curvature \( G_{A_y}^{G}(k) \) at \( k = 0 \). This corresponds to the phonon induced virtual direct inter-band transition process with the peak contribution concentrating at \( K \) and \( K' \) valley. The dependence of \( G_{A_y}^{G}(k) \) on \( k \) is plotted in Fig. 1(c) where one can find that the Berry curvature shows a peak at the phonon Brillouin zone center. Using by reasonably realistic parameters, e.g., \( t = 3 \text{ eV} \), \( t' = 0.02 \text{ eV} \), \( \partial_d t = 1 \text{ eV}/\AA \), we find that the peak of molecular Berry curvature corresponds to an effective magnetic field of \( \sim 10^3 \) Tesla. Thus, the effect of molecular Berry curvature can be large in materials with narrow electronic band gap, e.g., topological materials. In the small gap limit, we find an analytical formula for the peak value \( G_{A_y}^{G}(k) = \frac{2\pi\hbar C}{\beta(\partial_d t/t)^2} \) where \( C \) is the Chern number of the system as plotted in the Fig. 1(d). It is noted that the molecular Berry curvature vanishes at \( K \) and \( K' \) points due to the vanishing of the matrix elements in \( \partial_{\varepsilon \gamma H} \) between conduction and valence bands at different valleys in this model.

The formula above can be adopted by the first principle calculation directly, which is thus essential for exploring the phonon Hall effect in magnetic materials. The \( G_{A_y}^{G} \) is an analogy of the effective magnetic field in the Raman spin-lattice coupling model. In the Raman spin-lattice coupling model, the motion of \( u_{t,A_x} \) can only be influenced by \( \hat{u}_{t,A_y} \) on the same site. In contrast, the molecular Berry curvature distributes sharply around the Brillouin zone center. This distribution indicates that, by Fourier transforming back to the real space, the displacement \( u_{t,A_x} \) can be influenced by the velocity \( \hat{u}_{t,A_y} \) that is far away.

Moreover, the \( G \) matrix also has off-diagonal blocks with nonzero matrix element \( G_{B_y}^{G} \), which reflects the correlation between the motions of the A and the B atoms.

The amplitude of this term is comparable with \( G_{A_y}^{G} \) such that \( G_{A_y}^{G} = -G_{B_x}^{G} \) at \( k = 0 \). The off-diagonal block is thus important, which was completely neglected in the traditional Raman spin-lattice coupling, and can lead to a gap opening of the degenerate acoustic bands. Therefore, the molecular Berry curvature is a better choice to explore the influence of electronic states on phonons in a unified way.

### B. Phonon spectrum and chiral optical phonons

Once the Berry curvature is calculated for our model we can find the phonon spectrum using Eq. (15). The result of the numerical calculation of this equation is presented in Fig. 2. In this figure, we can see a gap opening between the optical branches at the \( \Gamma \) point. This band gap is proportional to the molecular Berry curvature. To show this relation, we employ the perturbation method since \( \delta \mathcal{G} \ll K_k \). From Eq. (14), one can find that

\[ \omega_{k,\nu}^2 = K_k \gamma_{\nu} + 2 \omega_{k,\nu} \delta \mathcal{G}_k \gamma_{\nu}. \]

The second term on the right hand side is treated as a perturbation. The unperturbed eigenvalues \( \omega_{1,2} \) and eigenstates \( \gamma^{0,2}_{1,2} \) for the optical branches at the \( \Gamma \) point can be obtained from \( \omega_{1,2} = K_k \gamma_{\nu} \). The solutions are \( \omega_{1,2} = \gamma_1 \) and \( \gamma_{1,2} = \frac{\omega_{1,2}}{2\omega_{1,2}} (1 \ 0 \ -1 \ 0)^T \) and \( \gamma_{2} = \frac{\omega_{1,2}}{2\omega_{1,2}} (0 \ 1 \ 0 \ -1)^T \). In the presence of the perturbation, the general eigenstate can be expressed as a linear...
combination $\tilde{\gamma} = c_1\gamma_1^0 + c_2\gamma_2^0$ with $c_1$ and $c_2$ being some constants to be determined. By expanding the phonon eigenvalue at the $\Gamma$ point to the first order as $\omega = \omega_T + \delta \omega$, one can find that

$$\delta \omega \begin{pmatrix} c_1 \\ c_2 \end{pmatrix} = \frac{2i\omega_T}{\omega_0} \begin{pmatrix} \gamma_1^0 \tilde{G} k \gamma_1^0 & \gamma_1^0 \tilde{G} k \gamma_2^0 \\ \gamma_2^0 \tilde{G} k \gamma_1^0 & \gamma_2^0 \tilde{G} k \gamma_2^0 \end{pmatrix} \begin{pmatrix} c_1 \\ c_2 \end{pmatrix}$$

(19)

where $\gamma_1^0 \gamma_1^0 = \frac{\omega_0}{\omega_0} \delta_{ij}$ is employed. Since $\tilde{G} k = -\tilde{G} k$, the matrix on the right hand side is Hermitian. Thus the diagonal terms are zero. We find that, by setting $c_1 = 1/\sqrt{2}$ and $c_2 = \pm i/\sqrt{2}$, the above matrix can be diagonalized with the phonon energy shifts $\delta \omega = \pm \frac{\hbar}{\omega} \text{Re} \left[ \tilde{G}(k=0) \right]$. Therefore, the optical phonons are split and the phonon polarizations become right- and left-handed polarized. The splitting of the phonon branches at the Brillouin zone center is expected to be observable in optical spectral experiments.

We would like to point out that, in the absence of the molecular Berry curvature, the dynamical matrix can be written as a real matrix at the Brillouin zone center. As a result, the phonons are always linearly polarized. In the presence of the molecular Berry curvature, however, phonons at the $\Gamma$ point become circularly polarized. This is different from the chiral phonon at the Brillouin zone corner, which has a degenerate state at the opposite momentum.

By using the phonon wavefunction, one can also define a phonon Berry connection and phonon Berry curvature. In Fig. 2(b), we plot the phonon Berry curvature along the high-symmetric line for the higher optical branch. Peaks appear at the points where the phonon polarization changes from circular around the $\Gamma$ point to linear away from that point. The phonon Berry curvature contributes to a nonzero Chern number 1. The Chern number for the lower optical branch is $-1$ whereas the acoustic branches have zero Chern numbers. Associated with the spectrum splitting, the Berry curvature of optical branches can also contribute to the thermal Hall effect.

C. Phonon angular momentum

The circular polarization of phonons also give rise to non nonzero phonon angular momentum that can be expressed as

$$J_{\text{ph}} = \sum_{l,\alpha} u_{l,\alpha} \times \dot{u}_{l,\alpha}.$$  

(20)

For a 2-dimensional system, the vertical component of the angular momentum becomes $J_{z,\text{ph}} = \sum_{l,\nu}(u_{l,\nu}\dot{u}_{l,\nu} - u_{l,\nu}^*\dot{u}_{l,\nu}^*)$. It can also be written in a matrix product form

$$J_{\text{ph}} = \sum_{k} u_{k}^L \tilde{G} k u_{k} = \sum_{k} u_{k}^L \left( p_k + \tilde{G} k u_k \right)$$

(21)

where $L$ is a real $2r \times 2r$ antisymmetric matrix for a system with $r$ atoms per unit cell. By using the second quantized expression for the canonical variables of atoms (Eqs. (9)-(10)), we calculate the angular momentum for each phonon branch (Fig. 3(a)). We find that the phonon angular momentum of both acoustic branches vanish whereas the circularly polarized optical branches are nearly quantized. This is in contrast with the phonon angular momentum obtained by using the Raman spin-lattice model which neglects the nonlocal effective magnetic field. In those calculations, the acoustic phonons at the Brillouin zone center split and can carry nonzero energy and nonzero angular momentum. The splitting of the acoustics bands is induced by breaking the Galilean translational symmetry due the Raman spin-lattice coupling term that meant to serve as an analogy to a uniformly charged lattice under a real magnetic field. This symmetry is respected by the molecular Berry curvature.

By summing over the angular momentum of all the phonon branches, we find a nonzero value as illustrated in Fig. 3(b). This indicates a finite zero-point lattice angular momentum in the zero temperature limit. At finite temperature, the thermal averaged phonon angular momentum is

$$\langle J_{z,\text{ph}} \rangle = -\sum_{k,\mu,\nu} \gamma_{k,\mu}\gamma_{k,\nu} \omega_{k,\mu}^{\nu} \left[ \frac{2f(\omega_{k,\mu})}{\omega_0} \right] \left( \frac{1}{2} + f(\omega_{k,\nu}) \right).$$

(22)

Here we used $b_{k,\mu}b_{k,\mu}^\dagger = \delta_{\mu,\nu} + b_{k,\mu}^\dagger b_{k,\nu}$, $\langle b_{k,\mu}b_{k,\mu}^\dagger b_{k,\nu}^\dagger b_{k,\nu} \rangle = \langle b_{k,\mu}b_{k,\nu} \rangle = \langle b_{k,\mu}b_{k,\nu} \rangle = 0$ and $\langle b_{k,\mu}b_{k,\nu}^\dagger \rangle = f(\omega_{k,\nu})\delta_{\mu,\nu}$, where $f(\omega_{k,\nu}) = \frac{1}{e^{\omega_{k,\nu}/k_B T} - 1}$ is the Bose-Einstein distribution. In

FIG. 3. (a) Contribution of each phonon band to the total phonon angular momentum, where $\tilde{G} k$ represents the angular momentum of each branch without the distribution, such that $\langle J_{z,\text{ph}} \rangle = \sum_{k,\mu,\nu} \gamma_{k,\mu}\gamma_{k,\nu} \omega_{k,\mu}^{\nu} \left[ \frac{2f(\omega_{k,\mu})}{\omega_0} \right] \left( \frac{1}{2} + f(\omega_{k,\nu}) \right)$ (b) Spectrum of total phonon angular momentum $J_{z}(k)$ from all four branches in the limit $T \rightarrow 0K$. (c) Phonon angular momentum of each unit cell in real space. The angular momentum vanishes in a classical limit $T \rightarrow \infty$. 
low temperature regime, the phonon angular momentum has a finite value as shown in Fig. 3(c). In this limit, an analytic expression for the phonon angular momentum at the Γ point can be found by using the perturbative approximation as:

\[ \langle J^\text{ph}_z \rangle_\Gamma = \frac{\hbar^2}{M_\omega} \text{Re}(G(k = 0)) \]  

(23)

which is consistent with the numerical calculations of Eq. (22). As the temperature increases, the thermal averaged phonon angular momentum tends to go to zero. As \( T \to \infty \), Eq. (22) approximates to

\[ \langle J^\text{ph}_z \rangle = -\sum_{k,\nu} \gamma^\nu_\downarrow L \gamma^\nu_\downarrow \left( \frac{2ik_B T}{\omega_0} + \frac{i\hbar^2 \omega^2_{\nu,\nu}}{6\omega_0 k_B T} \right) \]  

(24)

where the first term vanishes because \( \sum_{\nu} \gamma^\nu_\downarrow L \gamma^\nu_\downarrow = 0 \) (see Appendix G) and the second term decreases as \( 1/T \).

IV. SUMMARY

We formulated the molecular Berry curvature by using the single-particle Bloch wavefunctions in the absence of a uniform magnetic field. We studied its effect on the lattice dynamics and thus phonons. The quantized equations of motion of the lattice are solved by using the Bogoliubov transformation. We applied our theory to the Haldane model of a honeycomb lattice. For this model, the molecular Berry curvature is narrowly distributed around the Brillouin zone center, which indicates that, in real space, the motion of an ion can be influenced by the velocity of another atom that is far away. This is different from the Lorentz force on the nuclei induced by a magnetic field as well as the widely adopted Raman spin-lattice coupling model. The molecular Berry curvature lifts the degeneracy of optical phonons at the Γ point forming chiral phonons with left- and right-handed polarizations. These modes carry nonzero angular momentum and contribute to a nonzero total angular momentum in the low temperature limit and thus modify the Einstein-de Haas effect. These optical branches also carry nonzero phonon Berry curvature that can contribute to the thermal Hall effect.

APPENDIX

A. Effective lattice Hamiltonian from the time-dependent variational principle

The state of electrons is governed by the time-dependent Schrödinger equation. By assuming a normalized condition, it can be derived from the time-dependent variational principle with Lagrangian \( \mathcal{L}_e = \langle \Phi_0 | i\hbar \partial_t - H_e | \Phi_0 \rangle \) by minimizing the action with respect to any variation of \( \langle \Phi_0 \rangle \) in the bra space. Under the Born-Oppenheimer approximation, the electronic state lies at the instantaneous ground state of the Hamiltonian \( H_e \) that depends on the lattice configuration \( \{ R \} \). With known instantaneous ground state, one can integrate out the electronic degree of freedom to get the effective Lagrangian of lattice that reads

\[ \mathcal{L} = \sum_{l,\kappa} \frac{M_e}{2} \bar{R}^2_{l,\kappa} + \langle \Phi_0 | i\hbar \partial_t - H_e | \Phi_0 \rangle \]

(25)

\[ = \sum_{l,\kappa} \frac{M_e}{2} \bar{R}^2_{l,\kappa} + \langle \Phi_0 | i\hbar \partial_t | \Phi_0 \rangle - V_{\text{eff}}(\{ R \}) \]

\[ = \sum_{l,\kappa} \frac{M_e}{2} \bar{R}^2_{l,\kappa} + h A_{l,\kappa} \cdot \dot{R}_{l,\kappa} - V_{\text{eff}}(\{ R \}) \]

where \( \bar{R}_{\kappa,\kappa} \) labels the position of the \( \kappa \)-th atom in the \( l \)-th unit cell with mass \( M_e \). \( A_{l,\kappa} = \langle \Phi_0 | i\hbar \partial | \Phi_0 \rangle \) is the Berry connection. \( V_{\text{eff}}(\{ R \}) \) is the total energy of the electrons and ions at the configuration \( \{ R \} \) that forms the potential landscape of the ion. In the equilibrium configuration \( \{ \bar{R}^{\text{eq}} \} \), \( V_{\text{eff}} \) takes its minimum. From the Lagrangian, one can reveal the Hamiltonian Eq. [4] by Legendre transformation, which agrees with that derived by Mead and Truhlar [23].

B. The existence of a symmetric gauge near the equilibrium configuration

We consider a lattice where each atom vibrates around its equilibrium position with a displacement \( u \) where, in this paragraph, we use shorthand notation for these indices as \( \{ l, \kappa \} \rightarrow l \) and \( \{ l', \kappa' \beta \} \rightarrow l' \). In the small \( \{ u \} \) limit, we can expand the Berry connection \( A_l = \langle \Phi_0 | i\partial_l | \Phi_0 \rangle \) to the linear order of \( \{ u \} \) as \( A_l = A^0_l + \partial_l A_{l'u'} \) where the coefficients \( \partial_l A_{l'u'} \) are taken in the limit of \( \{ u \} \rightarrow 0 \) and thus are independent of \( \{ u \} \).\( \partial_l A_{l'u'} \) is the Berry connection \( A_l \) is expressed in a parameter space of high dimension. It is questionable whether there exists a gauge transform such that \( \delta A_l = A_l - \delta \chi \). By definition, \( \delta A_l = A^0_l + \sum_{\kappa} u_l(\frac{1}{2} \langle \partial_l | \Phi_0 | \partial_l | \Phi_0 \rangle + \frac{1}{2} \langle \partial_l | \Phi_0 | | \Phi_0 \rangle + \langle \Phi_0 | | \Phi_0 \rangle ) \). It can be verified that \( \partial_l \delta A_{l'} - \partial_l \delta A_{l'} = 0 \). According to Poincaré’s Lemma, there always exists locally a scalar function \( \chi \) such that \( \delta A_l = \partial_l \chi \). One can
thus perform such a gauge transformation $e^{i\chi} |\Phi_0\rangle$ to obtain the Berry connection in the symmetric form.

We can now express the Berry connection (gauge field) in a symmetric gauge. The gauge invariant Berry curvature can be written as

$$G^{\kappa_\beta}_\alpha (R_l^0 - R_{l'}^0) = \left[ \frac{\partial A_{l',\kappa_\beta}}{\partial u_{l,\kappa_\alpha}} - \frac{\partial A_{l,\kappa_\alpha}}{\partial u_{l',\kappa_\beta}} \right].$$

Near the equilibrium position, the Berry connection in the symmetric gauge is

$$A_{\kappa\alpha}(R_0^0) = -\frac{1}{2} \sum_{l',\kappa'\beta} G^{\kappa'\beta}_\alpha (R_l^0 - R_{l'}^0) u_{l',\kappa'}(R_l^0)$$

and in momentum space:

$$A_{\kappa\alpha}(k) = -\sum_{\kappa',\beta} \frac{1}{2} G^{\kappa'\beta}_\alpha (k) u_{\kappa'\beta}(k)$$

C. Symmetry constraints on the molecular Berry curvature

In the presence of time reversal symmetry, the Berry curvature $G^{\kappa'\beta}_\alpha (R_l^0 - R_{l'}^0)$ is symmetric.

D. Molecular Berry curvature in non-interacting electronic system

The molecular Berry curvature can be expressed in general by the many-body wavefunction $\{\Phi_n\}$ where $n = 0$ stands for the ground state and the $n > 0$ are excited states.

$$G^{\kappa'\beta}_\alpha (k) = \frac{1}{N} \sum_n \sum_{l'} G^{\kappa\alpha'}_\beta (R_l^0 - R_{l'}^0) e^{-ik\cdot(R_l^0 - R_{l'}^0)}$$

$$= \frac{1}{N} \sum_n \sum_{l',n} i \left[ \frac{\partial \Phi_0}{\partial u_{l,\kappa_\alpha}} |\Phi_n\rangle \langle \Phi_n | \frac{\partial \Phi_0}{\partial u_{l',\kappa'\beta}} \right] - \left[ u_{l,\kappa_\alpha} \leftrightarrow u_{l',\kappa'\beta} \right] e^{-ik\cdot(R_l^0 - R_{l'}^0)}$$

$$= \frac{i}{N} \sum_{n \neq 0} \frac{\left[ \langle \Phi_0 | \sum_{l} \frac{\partial H_{\kappa_\alpha\kappa_\beta}}{\partial u_{l,\kappa_\alpha}} e^{-ik\cdot R_l^0} |\Phi_n\rangle \langle \Phi_n | \sum_{l'} \frac{\partial H_{\kappa'\beta\kappa_\alpha}}{\partial u_{l',\kappa'\beta}} e^{-ik\cdot R_{l'}^0} |\Phi_0\rangle \right]}{(E_n - E_0)^2}$$

$$- \frac{\left[ \langle \Phi_0 | \sum_{l'} \frac{\partial H_{\kappa'\beta\kappa_\alpha}}{\partial u_{l',\kappa'\beta}} e^{-ik\cdot R_{l'}^0} |\Phi_n\rangle \langle \Phi_n | \sum_{l} \frac{\partial H_{\kappa_\alpha\kappa_\beta}}{\partial u_{l,\kappa_\alpha}} e^{-ik\cdot R_l^0} |\Phi_0\rangle \right]}{(E_n - E_0)^2}$$

$$= \frac{i}{N} \sum_{n \neq 0} \frac{\langle \Phi_0 | M_{\kappa_\alpha\kappa_\beta} |\Phi_n\rangle \langle \Phi_n | M_{\kappa_\alpha\kappa_\beta} |\Phi_0\rangle - \langle \Phi_0 | M_{\kappa_\alpha\kappa'\beta} |\Phi_n\rangle \langle \Phi_n | M_{\kappa_\alpha\kappa'\beta} |\Phi_0\rangle}{(E_n - E_0)^2}$$

where $M_{\kappa_\alpha\kappa_\beta} = \sum_l \frac{\partial H_{\kappa_\alpha\kappa_\beta}}{\partial u_{l,\kappa_\alpha}} e^{-ik\cdot R^0_l}$ in the $u_l \to 0$ limit. In this limit, the $M_{\kappa_\alpha\kappa_\beta}$ involves only single electron scattering process.

In the non-interacting system, the ground state is a product state composed of single-particle states below the chemical potential $\mu$ with $|\Phi_0\rangle = \Pi_{\alpha < \mu c_{m,q}^\dagger} |\Phi_0\rangle$ and $c_{m,q}^\dagger$ being the creation operator of the state at the momentum $q$ of the $m$-th band. The excited states can be expressed $|\Phi_n\rangle$ is the many body states with one occupied excited state and a hole. One can then express the Berry curvature in single particle wavefunction as...
\[ G_{\kappa' \beta}(k) = \frac{i}{N} \sum_{q} \sum_{\varepsilon_m < \mu, \varepsilon_m' > \mu} \frac{\phi_{m,q}^{\dagger} M_{k,\kappa} \phi_{m',q+k}^* \phi_{m',q+k} M_{k,\kappa'} \phi_{m,q}}{\left( \varepsilon_{m,q} - \varepsilon_{m',q+k} \right)^2} - \frac{\phi_{m,q+k}^{\dagger} M_{-k,\kappa'} \phi_{m,q} \phi_{m',q+k} M_{-k,\kappa} \phi_{m,q+k}}{\left( \varepsilon_{m,q+k} - \varepsilon_{m',q} \right)^2} \] (30)

In the following, we focus on the Haldane model to calculate the molecular Berry curvature explicitly. We take \( G_{A_y}(k) \) as an example by setting \( u_{l,A_x} = u_{l,A_x} \) and \( u_{l,A_y} = u_{l,A_y} \). For this particular case, we have:

\[
M_{k,A_x} = \sum_{l,i} \frac{\partial H_e}{\partial u_{l,A_x}} e^{-ikR_i^a} = \sum_{l,i} -\frac{\partial t_i}{\partial u_{l,A_x}} b_i^\dagger R_i^a + h.c. e^{-ikR_i^a}
\]

where \( t_i \) with \( i = 1-3 \) represents the hopping from site A in the unit cell \( R_i^a \) to the site B in the unit cell of \( R_i^a - R_k \) with \( R_1 = (a/2, a\sqrt{3}/2), R_2 = (a, 0), R_3 = (0, 0) \) as shown in Fig. 4. Here, we have \( \frac{\partial t_i}{\partial u_{l,A_x}} = 0 \), \( \frac{\partial t_i}{\partial u_{l,A_y}} = \sqrt{3} \frac{\partial t_i}{\partial u_{l,A_x}} \) which are independent of \( l \) and \( \partial t_i \) represents the gradient of hopping energy between two adjacent sites along the bond between them, which we take to be \( \partial t_i = 1 \text{ eV/Å} \).

By using the Fourier transformation \( a_l = \frac{1}{\sqrt{2N}} \sum_q a_q e^{iqR_i^a} \), we find that

\[
M_{k,A_x} = \frac{\sqrt{3} \partial t_i}{2} \sum_q b_q^\dagger a_{q+k} \left( e^{iqR_2} - e^{-iqR_3} \right)
+ \frac{\sqrt{3} \partial t_i}{2} \sum_q a_q^\dagger b_{q+k} \left( e^{-i(q+k)R_2} - e^{i(q+k)R_3} \right)
= \sum_q \left( a_q^\dagger b_q^\dagger \right) \partial_x \mathcal{H} \left( \frac{a_{q+k}}{b_{q+k}} \right)
\]

(31)

where \( \partial_x \mathcal{H} \) is a 2 \times 2 matrix with only off diagonal elements:

\[
(\partial_x \mathcal{H})_{12} = \frac{\sqrt{3}}{2} \partial t_i \left( e^{-i(q+k)R_2} - e^{i(q+k)R_3} \right)
+ \frac{\sqrt{3}}{2} \partial t_i \left( e^{iqR_2} - e^{-iqR_3} \right).
\]

This is an expression in terms of a single particle wavefunctions and eigenstates. Since only the relative motion of atoms generate the Berry curvature \( u_{l,v} = u_{l,v} \Rightarrow du_{l,v} = -du_{l,v} \), where \( u_{l,v} \) and \( u_{l,v} \) are displacements of two different atoms, all 16 different combinations of atoms will generate only 4 independent values of Berry curvature:

\[ G_{A_x}(k) = -G_{A_y}(k) = G_{B_y}(k) = -G_{B_x}(k) \equiv G_1(k) \]
\[ G_{A_y}(k) = -G_{A_y}(k) = G_{B_x}(k) = -G_{B_y}(k) \equiv G_2(k) \]
\[ G_{B_y}(k) = -G_{B_x}(k) = G_{B_y}(k) = -G_{B_x}(k) \equiv G_3(k) \]
\[ G_{A_x}(k) = G_{A_y}(k) = G_{B_x}(k) = G_{B_y}(k) \equiv 0 \]

E. Phonon modes of a honeycomb lattice

1. Hamiltonian for the lattice dynamics

A semi-classical Hamiltonian of the lattice in the adiabatic approximation can be written in a matrix form as
and displacement vectors can be expressed as:

\[ \vec{\Delta} = \sum_{i} \frac{1}{2} \left( \vec{p}_i - \hbar \vec{\hat{A}} \right) \right) \}

\[ = \sum_{k} \frac{1}{2} \left( \vec{p}_k - \hbar \vec{\hat{A}}_k \right)^{\dagger} (\vec{p}_k - \hbar \vec{\hat{A}}_k) + \{ \{ \vec{u}_k \} \}

\[ = \sum_{k} \frac{1}{2} \left( \vec{p}_k + \vec{\hat{G}}_k \vec{u}_k \right)^{\dagger} (\vec{p}_k + \vec{\hat{G}}_k \vec{u}_k) + \sum_{k} \frac{1}{2} \vec{u}_k^{\dagger} \vec{K}_k \vec{u}_k \]

where the first term is a kinetic energy of atomic vibrations and the latter is the effective interaction of the atoms mediated by the dynamics of electrons. Here the masses have been absorbed into the definition of momentum and displacement vectors. For a lattice with 2 atoms per unit cell, such as a honeycomb lattice, the momentum and displacement vectors can be expressed as:

\[ \vec{p}_k = \begin{pmatrix} \vec{p}_{kA} \bar{X} \sqrt{M_A} \\ \vec{p}_{kA} \bar{Y} \sqrt{M_A} \end{pmatrix} \]

\[ \vec{u}_k = \begin{pmatrix} \vec{u}_{k \bar{X}} \sqrt{M_B} \\ \vec{u}_{k \bar{Y}} \sqrt{M_B} \end{pmatrix} \]

and a gauge field matrix as:

\[ \vec{\hat{G}}_k = \frac{\hbar}{2} \begin{pmatrix} G_\xi(k) & G_\eta(k) & 0 & G_\zeta(k) \\ \frac{\bar{X}}{M_A} G_\xi(k)^* & \frac{\bar{X}}{M_A} G_\eta(k)^* & \frac{\bar{X}}{M_A M_B} G_\zeta(k) & \frac{\bar{X}}{M_A M_B} G_\zeta(k) \\ 0 & \frac{\bar{X}}{M_A M_B} G_\zeta(k)^* & -\frac{\bar{X}}{M_A} G_\xi(k) & -\frac{\bar{X}}{M_A} G_\eta(k) \\ -\frac{\bar{X}}{M_A M_B} G_\zeta(k) & -\frac{\bar{X}}{M_A M_B} G_\zeta(k) & \frac{\bar{X}}{M_A} G_\xi(k)^* & \frac{\bar{X}}{M_A} G_\eta(k)^* \end{pmatrix} \]

which is a skew-Hermitian matrix by definition. Here \( \vec{K}_k \) is a force constant matrix (in units of \( eV/\bar{u} \bar{A}^2 \)), \( u \)-atomic mass unit) defined as:\(^{25}\)

\[ \vec{K}_k = \begin{pmatrix} \frac{K_{01} + K_{02} + K_{03}}{\sqrt{M_A M_B}} & \frac{-K_{01} e^{-i k \cdot R_1} + K_{03} e^{i k \cdot R_2}}{\sqrt{M_A M_B}} \\ \frac{-K_{01} e^{i k \cdot R_1} + K_{03} e^{-i k \cdot R_2}}{\sqrt{M_A M_B}} & \frac{K_{01} + K_{02} + K_{03}}{\sqrt{M_A M_B}} \end{pmatrix} \]

where \( k \cdot R_1 = k_x a_1 + \sqrt{3} k_y a_2 \) and \( k \cdot R_2 = k_x a_1 \), with \( a \) being a distance between two neighboring unit cells with unit vectors \((a, 0)\) and \((a/2, a \sqrt{3}/2)\). Here \( K_{01} = U(\pi/2)K_x U(-\pi/2) \), \( K_{02} = U(\pi/6)K_x U(-\pi/6) \) and \( K_{03} = U(-\pi/6)K_x U(\pi/6) \) is a spring constant matrix constructed from longitudinal and transverse spring constants \( K_L \) and \( K_T \), and

\[ U(\theta) = \begin{pmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{pmatrix} \]

is a 2-dimensional rotation operator in \( x - y \) plane. Combining all these we obtain the lattice Hamiltonian as in Eq. (33).

Considering all these the lattice Hamiltonian can be written as:

\[ \hat{H}_L = \sum_{k} \frac{1}{2} \left[ \hat{p}_k^{\dagger} \hat{p}_k + \hat{u}_k^{\dagger} D_k \hat{u}_k + (\hat{p}_k^{\dagger} \hat{\hat{G}}_k \hat{u}_k + h.c.) \right] \]

(34)

where \( D_k = K_k + \hat{G}_k^{\dagger} \hat{G}_k \). We then can get a pair of canonical equations of motion

\[ \hat{p}_k = -\frac{\partial H}{\partial \hat{u}_{-k}} = \hat{G}_k \hat{p}_k - D_k \hat{u}_k \]

\[ \hat{u}_k = \frac{\partial H}{\partial \hat{p}_{-k}} = \hat{p}_k + \hat{G}_k \hat{u}_k. \]

(35)

(36)

2. Second quantization with Bogoliubov transformation

After introducing the second quantization of displacement and momentum as \(^{33}\) \( \hat{u}_k = \sqrt{\frac{\hbar}{2 \omega_0}} (a_{-k}^\dagger + a_k) = \sqrt{\frac{\hbar}{2 \omega_0}} u_k \) and \( \hat{p}_k = i \sqrt{\frac{\hbar \omega_0}{2}} (a_{-k}^\dagger - a_k) = \sqrt{\frac{\hbar \omega_0}{2}} \hat{p}_k \), where \( a_{-k}^\dagger \) and \( a_k \) represent column vectors of creation and annihilation operators, the canonical equations of motion can be combined into a matrix form:

\[ \begin{pmatrix} \hat{u}_k \\ \hat{p}_k \end{pmatrix} = \begin{pmatrix} \hat{G}_k & \frac{\hbar \omega_0}{2} \hat{G}_k \\ -\frac{\hbar \omega_0}{2} \hat{G}_k & \hat{G}_k \end{pmatrix} \begin{pmatrix} \hat{u}_k \\ \hat{p}_k \end{pmatrix} \]

(37)

Now replacing \( \begin{pmatrix} \hat{u}_k \\ \hat{p}_k \end{pmatrix} = \begin{pmatrix} \frac{1}{\sqrt{2}} \hat{u}_k + \frac{1}{\sqrt{2}} \hat{v}_k \\ \frac{1}{\sqrt{2}} \hat{u}_k - \frac{1}{\sqrt{2}} \hat{v}_k \end{pmatrix} \) we can obtain:
\[
\begin{pmatrix}
-\frac{1}{2} i & 0 \\
0 & \frac{1}{2} i
\end{pmatrix}
\begin{pmatrix}
\hat{a}_k^- \\
\hat{a}_k^+
\end{pmatrix}
= \frac{1}{2} \left( \frac{D_k}{\omega_0} + \frac{1}{2} \omega_0 - 2i \tilde{G}_k \right)
\begin{pmatrix}
\hat{a}_k^- \\
\hat{a}_k^+
\end{pmatrix}
= \frac{D_k}{\omega_0} - \frac{1}{2} \omega_0 - i \omega_0
\begin{pmatrix}
\hat{a}_k^- \\
\hat{a}_k^+
\end{pmatrix}
= \frac{D_k}{\omega_0} + \frac{1}{2} \omega_0 + 2i \tilde{G}_k
\begin{pmatrix}
\hat{a}_k^- \\
\hat{a}_k^+
\end{pmatrix}
\]
}

where \( \Omega_k^* \) is an 8 \times 8 positive semi-definite Hermitian matrix. The notations \( \Omega_k \) was chosen for the convenience that will be clear shortly. Now we introduce the Bogoliubov transformation as

\[
a_k = \sum_\nu \left( \alpha_\nu b_{k,\nu} + \beta_\nu b_{\nu,k}^\dagger \right)
\]

\[
\hat{a}_k^\dagger = \sum_\nu \left( \alpha_\nu^* b_{\nu,k} + \beta_\nu^* b_{\nu,k}^\dagger \right)
\]

where the tilde represents the transpose of the vector and the summation is over all the branches. Here \( b_{k,\nu} \)

\( \left( b_{\nu,k}^\dagger \right) \) are single valued Bogoliubov operators corresponding to each branch and \( \alpha_\nu \) and \( \beta_\nu \) are column vectors of 4 elements corresponding to each degree of freedom. We require that each Bogoliubov operators represent the eigenstates with a specific frequency \( \omega_\nu \) and the summation is over all the branches. Here \( \tilde{H}_k \) is an effective Hamiltonian which is an 8 \times 8 Hermitian matrix and can be solved to find the eigenvalues and the summation is over all the branches. Here \( \tilde{H}_k \)

\[
\tilde{H}_k = \tilde{H}_k \tilde{a}_k = \tilde{H}_k \tilde{a}_k^\dagger
\]

where \( \tilde{a}_k \) and \( \tilde{a}_k^\dagger \) are the new operators corresponding to each branch and \( \tilde{a}_k \) and \( \tilde{a}_k^\dagger \) are the eigenstates of \( \tilde{H}_k \) and \( \tilde{H}_k \) is a positive semidefinite matrix and we conclude that only positive solutions of \( \tilde{H}_k \) should be considered as physical.

Alternatively, if we switch to a new basis as \( \gamma_\nu = \frac{1}{\sqrt{2}} (\alpha_\nu + \beta_\nu) \) and \( \bar{\gamma}_\nu = \frac{1}{\sqrt{2}} (\alpha_\nu - \beta_\nu) \) Eq. (44) can be rewritten as

\[
\omega_{k,\nu} \begin{pmatrix}
\gamma_\nu \\
\bar{\gamma}_\nu
\end{pmatrix}
= \left( \frac{D_k}{\omega_0} - \frac{1}{2} \omega_0 \right)
\begin{pmatrix}
\gamma_\nu \\
\bar{\gamma}_\nu
\end{pmatrix}
\]

with the normalization condition resulted from Eq. (41): \( \gamma_\nu^\dagger \gamma_\nu + \bar{\gamma}_\nu^\dagger \bar{\gamma}_\nu = 1 \)

From this we can construct a more compact eigenvalue problem: multiplying both sides of Eq. (51) by \( \sigma_x \) we obtain

\[
\omega_{k,\nu} \sigma_x \psi_\nu = \left( \frac{D_k}{\omega_0} - \frac{1}{2} \omega_0 \right) \psi_\nu = \Omega_k \psi_\nu
\]

where \( \psi_\nu = \begin{pmatrix}
\gamma_\nu \\
\bar{\gamma}_\nu
\end{pmatrix} \). Here \( \Omega_k \) is again a semi-definite positive matrix and for that we can introduce new eigenstate as \( \tilde{\psi}_\nu = \Omega_k^{1/2} \psi_\nu \) and obtain:

\[
\omega_{k,\nu} \tilde{\psi}_\nu = \Omega_k^{1/2} \sigma_x \Omega_k^{1/2} \tilde{\psi}_\nu = H_{eff} \tilde{\psi}_\nu
\]

where effective Hamiltonian \( H_{eff} \) introduced above is Hermitian and can be solved to find the eigenvalues \( \omega_{k,\nu} \). The result of numerical calculation of this equation is same as the one obtained from Eq. (46).
F. Determinant of the eigenvalues and related

The effective Hamiltonian can be written as $H_{\text{eff}} = \Omega_k^{1/2} (\sigma_x \otimes I_d) \Omega_k^{1/2}$ where $I_d$ is the identity matrix with the dimension $d$ being that of the $K$ matrix. Thus the determinant $\det H_{\text{eff}} = \det (\omega_l I_p) \cdot \det(D/\omega_l - \imath G(\omega_l I_q)^{-1}) = \det(D + G^2) = \det(D - GG^\dagger) = \det K$.

By the definition of $\Omega_k$, one can find that $\Omega_{\ldots k} = U^\dagger \Omega_k U$ with $U = \sigma_z$. Thus, $H_{\text{eff}}(-k) = (U^\dagger \Omega_k U)^{1/2} \sigma_x (U^\dagger \Omega_k U)^{1/2}$. By noting that $(U^\dagger \Omega_k U)^{1/2} = U^\dagger \Omega_{\ldots k} U^\dagger$, one can find that $H_{\text{eff}}(-k) = -U^\dagger H_{\text{eff}}(k)^* U$

G. Phonon angular momentum

A classical angular momentum phonons is defined as:

$$J_z^{\text{ph}} = \sum_{l,k} T \left( \begin{array}{cc} 0 & 1 \\ -1 & 0 \end{array} \right) (u_{l,k}^x u_{l,k}^y - u_{l,k}^y u_{l,k}^x)$$

$$= \sum_{l,k} T \left( \begin{array}{cc} u_{l,k}^x & u_{l,k}^y \\ u_{l,k}^{y \dagger} & u_{l,k}^{x \dagger} \end{array} \right) \left( \begin{array}{cc} 0 & 1 \\ -1 & 0 \end{array} \right) \left( \begin{array}{cc} u_{l,k}^x & u_{l,k}^y \\ u_{l,k}^{y \dagger} & u_{l,k}^{x \dagger} \end{array} \right)$$

$$= \sum_{k} \left( \begin{array}{cc} \gamma_{k}^{A,x} \gamma_{k}^{A,y} \\ \gamma_{k}^{B,x} \gamma_{k}^{B,y} \end{array} \right) \left( \begin{array}{cc} 0 & 1 \\ 1 & 0 \\ 0 & 0 \\ 0 & 1 \end{array} \right) \left( \begin{array}{cc} \gamma_{k}^{A,y} & 0 \\ 0 & \gamma_{k}^{A,x} \\ 0 & \gamma_{k}^{B,y} \\ 0 & \gamma_{k}^{B,x} \end{array} \right)$$

$$= \sum_{k} \left( \gamma_{k}^{A,x} \gamma_{k}^{A,y} \right) \left( \begin{array}{cc} 0 & 1 \\ 1 & 0 \\ 0 & 0 \end{array} \right) + \sum_{k} \left( \gamma_{k}^{B,x} \gamma_{k}^{B,y} \right) \left( \begin{array}{cc} 0 & 0 \\ 0 & 1 \\ 1 & 0 \end{array} \right)$$

$$= \sum_{k} u_k^A L u_k + \sum_{k} u_k^B L (p_k + G_k u_k)$$

We replace the canonical variables with

$$u_k = \sqrt{\frac{\hbar}{\omega_k}} \left( \begin{array}{c} \gamma_{k}^{A,x} \gamma_{k}^{A,y} \\ \gamma_{k}^{B,x} \gamma_{k}^{B,y} \end{array} \right)$$

and

$$p_k = \sum_{\nu} \sqrt{\frac{\hbar}{\omega_k}} \left( \gamma_{k}^{A,x} \gamma_{k}^{A,y} - \gamma_{k}^{B,x} \gamma_{k}^{B,y} \right)$$

We get the expression for the phonon angular momentum as:

$$J_z^{\text{ph}} = \sum_{k,\mu,\nu} \hbar \left( i \gamma_{k,u}^{T} L \gamma_{u}^{*} + \frac{1}{\omega_k} \gamma_{k}^{T} L G \gamma_{k}^{*} \right) b_{-k,\mu} b_{k,\nu}^\dagger$$

$$+ \sum_{k,\mu,\nu} \hbar \left( -i \gamma_{k,u}^{T} L \gamma_{u}^{*} + \frac{1}{\omega_k} \gamma_{k}^{T} L G \gamma_{k}^{*} \right) b_{k,\mu} b_{-k,\nu}$$

$$+ \sum_{k,\mu,\nu} \hbar \left( i \gamma_{k,u}^{T} L \gamma_{u}^{*} + \frac{1}{\omega_k} \gamma_{k}^{T} L G \gamma_{k}^{*} \right) b_{k,\mu} b_{-k,\nu}$$

$$+ \sum_{k,\mu,\nu} \hbar \left( i \gamma_{k,u}^{T} L \gamma_{u}^{*} + \frac{1}{\omega_k} \gamma_{k}^{T} L G \gamma_{k}^{*} \right) b_{k,\mu} b_{-k,\nu}$$

We can calculate the thermal average of this expression. Since $b_{k,\nu} b_{k,\mu} = \delta_{\mu,\nu} b_{k,\mu}^\dagger b_{k,\mu}$ and $\langle b_{k,\mu}^\dagger b_{k,\nu} \rangle = f(\omega_k) \delta_{\mu,\nu}$, we get:

$$\langle J_z^{\text{ph}} \rangle = \sum_{k,\nu} \hbar \left( i \gamma_{k,u}^{T} L \gamma_{u}^{*} + \frac{1}{\omega_k} \gamma_{k}^{T} L G \gamma_{k}^{*} \right) \left( 1 + f(\omega_k) \right)$$

$$+ \sum_{k,\nu} \hbar \left( -i \gamma_{k,u}^{T} L \gamma_{u}^{*} + \frac{1}{\omega_k} \gamma_{k}^{T} L G \gamma_{k}^{*} \right) f(\omega_k,\nu)$$

$$= \sum_{k,\nu} \hbar \left( \frac{1}{\omega_k} \gamma_{k}^{T} L G \gamma_{k}^{*} \right) \left( 1 + f(\omega_k,\nu) \right)$$

$$= \sum_{k,\nu} \hbar \gamma_{k,u}^{T} L \gamma_{u}^{*} \left( \frac{i \hbar \omega_k}{\omega_k} \right) \left( 1 + 2 f(\omega_k,\nu) \right)$$

Here we should show that

$$\sum_{\nu} \gamma_{k,u}^{T} L \gamma_{u}^{*} = 0$$

$$\sum_{\nu} \gamma_{k,u}^{T} L \gamma_{u}^{*} = \text{Tr} \gamma_{k}^{T} L \gamma_{k}^{*}$$

$$= \text{Tr} \gamma_{k}^{T} L \gamma_{k}^{*}$$

$$= \text{Tr} \frac{1}{\omega_k} \gamma_{k}^{T} L G \gamma_{k}^{*}$$

$$= \text{Tr} \frac{1}{\omega_k} \gamma_{k}^{T} L G \gamma_{k}^{*}$$

$$= \text{Tr} G \gamma_{k}^{T} L G \gamma_{k}^{*}$$

$$= \text{Tr} G \gamma_{k}^{T} L G \gamma_{k}^{*}$$

$$= \text{Tr} G \gamma_{k}^{T} L G \gamma_{k}^{*}$$

$$= \text{Tr} G \gamma_{k}^{T} L G \gamma_{k}^{*}$$

$$= \text{Tr} G \gamma_{k}^{T} L G \gamma_{k}^{*}$$

where $\omega_k$ is the eigen-energy, which is a diagonal matrix, and $\hat{L} = \left( \begin{array}{cc} L & 0 \\ 0 & 0 \end{array} \right)$.
