Abstract

In this paper we determine the complexity of a broad class of problems that extends the temporal constraint satisfaction problems in [6]. To be more precise we study the problems Poset-SAT(\(\Phi\)), where \(\Phi\) is a given set of quantifier-free \(\leq\)-formulas. An instance of Poset-SAT(\(\Phi\)) consists of finitely many variables \(x_1, \ldots, x_n\) and formulas \(\varphi_i(x_{i1}, \ldots, x_{ik})\) with \(\varphi_i \in \Phi\); the question is whether this input is satisfied by any partial order on \(x_1, \ldots, x_n\) or not. We show that every such problem is NP-complete or can be solved in polynomial time, depending on \(\Phi\).

All Poset-SAT problems can be formalized as constraint satisfaction problems on reducts of the random partial order. We use model-theoretic concepts and techniques from universal algebra to study these reducts. In the course of this analysis we establish a dichotomy that we believe is of independent interest in universal algebra and model theory.

1 Introduction

Reasoning about temporal knowledge is a common task in various areas of computer science, for example Artificial Intelligence, Scheduling, Computational Linguistics and Operations Research. In many application temporal constraints are expressed as collections of relations between time points or time intervals. A typical computational problem is then to determine whether such a collection is satisfiable or not.

A lot of research in this area concerns only linear models of time. In particular there exists a complete classification of all satisfiability problems for linear temporal constraints in [6]. However, it has been observed many times that more complex time models are helpful, for instance in the analysis of concurrent and distributed systems or certain planning domains. A possible generalizations is to model time by partial orders (e.g. in [10], [1]).

Some cases of the arising satisfiability problems have already been studied in [13]. We will give a complete classification in this paper. Speaking more formally, let \(\Phi\) be a set of

A complexity dichotomy for poset constraint satisfaction

quantifier-free formulas in the language consisting of a binary relation symbol $\leq$. Then Poset-SAT($\Phi$) asks if constraint expressible in $\Phi$ are satisfiable by a partial order or not. We are going to give a full complexity classification of problems of the type Poset-SAT($\Phi$). In particular we are going to show that every such problem is NP-complete or solvable in polynomial time.

The proof of our result is based on a variety of methods and results. A first step is that we give a description of every Poset-SAT problem as constraint satisfaction problem over a countably infinite domain, where the constraint relations are first-order definable over the random partial order, a well-known structure in model theory.

A helpful result has already been established in the form of the classification of the closed supergroups of the automorphism group of the random partial order in [18]. We extend this analysis to closed transformation monoids. Informally, then our result implies that we can identify three types of Poset-SAT problems: (1) trivial ones (i.e., if there is a solution, there is a constant solution), (2) problems that can be reduced to the problems studied in [6] and (3) CSPs on templates that are model-complete cores.

So we only have to study problems in the third class. The basic method to proceed then is the universal-algebraic approach to constraint satisfaction problems. Here, one studies certain sets of operations (known as polymorphism clones) instead of analysing the constrains themselves. An important tool to deal with polymorphisms over infinite domains is Ramsey theory. We need a Ramsey result for partially ordered sets from [20] for proving that polymorphisms behave regularly on large parts of their domain. This allows us to perform a more simplified combinatorial analysis.

This paper has the following structure: In Section 2 we introduce some basic notation and show how every Poset-SAT problem is equal to a constraint satisfaction problem on a reduct of the random partial order. In Section 3 we give a brief introduction to the universal-algebraic approach and the methods from Ramsey theory that we need for our classification. Section 4 contains a preclassification, by the analysis of closed transformation monoids containing the automorphism group of the random partial order. This is followed by the actual complexity analysis using the universal algebraic approach. In Section 9 we summarize our results to show the complexity dichotomy for Poset-SAT problems.

We further show in Section 9 that an even stronger dichotomy holds, regarding the question whether certain reducts of the random partial order allow pp-interpretations of all finite structures or not (cf. the discussion in [11] and [22]). In this respect the situation is similar to previous classifications for CSPs where the constraints are first-order definable over the rational order [6], the random graph [10], or the homogeneous binary branching C-relation [17].

2 Preliminaries

In this section we fix some standard terminology and notation. When working with relational structures it is often convenient not to distinguish between a relation and its relational symbol. We will also do so on several occasions, but this should never cause any confusion.

Let $\leq$ always denote a partial order relation, i.e. a binary relation that is reflexive, antisymmetric and transitive. Let $<$ be the corresponding strict order defined by $x \leq y \land x \neq y$. Let $x \perp y$ denote the incomparability relation defined by $\neg(x \leq y) \land \neg(y \leq x)$. Sometimes we will write $x < y_1 \cdots y_n$ for the conjunction of the formulas $x < y_i$ for all $1 \leq i \leq n$. Similarly we will use $x \perp y_1 \cdots y_n$ if $x \perp y_i$ holds for all $1 \leq i \leq n$. 

2.1 Poset-SAT(Φ)

Let $\phi(x_1, \ldots, x_n)$ be a formula in the language that only consists of the binary relation symbol $\leq$. Then we say that $\phi(x_1, \ldots, x_n)$ is satisfiable if there exists a partial order $(A; \leq)$ with elements $a_1, \ldots, a_n$ such that $\phi(a_1, \ldots, a_n)$ holds in $(A; \leq)$. In this case we call $(A; \leq)$ a solution to $\phi$.

Let $\Phi = \{\phi_1, \phi_2, \ldots, \phi_k\}$ be a finite set of quantifier free $\leq$-formulas. Then the poset satisfiability problem Poset-SAT($\Phi$) is the following computational problem:

**Poset-SAT($\Phi$):**

**Instance:** A finite set of variables $\{x_1, \ldots, x_n\}$ and a finite set of formulas $\Psi$ that is obtained from $\phi \in \Phi$, by substituting the variables of $\phi$ by variables from $\{x_1, \ldots, x_n\}$

**Question:** Is there a partial order $(A; \leq)$ that is a solution to all formulas in $\Psi$?

- **Example 1.** An instance of Poset-SAT($\{<\}$) is given by variables in $\{x_1, \ldots, x_n\}$ and formulas in $\Psi$ of the form $x_i < x_j$. The question is, if there is a partial order on $\{x_1, \ldots, x_n\}$ that satisfies all formulas $x_i < x_j$ in $\Psi$. It is easy to see that such a partial order always exists if $\Psi$ does not contain formulas $x_{i_1} < x_{i_2}, \ldots, x_{i_{n-1}} < x_{i_n}, x_{i_n} < x_{i_1}$. The existence of such “cycles” in $\Psi$ can be verified in polynomial time, thus Poset-SAT($\{<\}$) is tractable.

   Every partial order can be extended to a total order. Therefore there is a solution to $I$ if and only if there is a totally ordered solution to $I$. So Poset-SAT($\{<\}$) is the same problem as the corresponding temporal constraint satisfaction problem Temp-SAT($\{<\}$), i.e. the question if there is a total order that is a solution to the input.

- **Example 2.** We define the betweenness relation $\text{Betw}(x, y, z) := (x < y \land y < z) \lor (z < y \land y < x)$. Again an instance of Poset-SAT($\{\text{Betw}\}$) is accepted if and only if it is accepted by Temp-SAT($\{\text{Betw}\}$). It is know that Temp-SAT($\{\text{Betw}\}$) is NP-complete, so Poset-SAT($\{\text{Betw}\}$) is NP-complete. We remark that if every relation in $\Phi$ is positively definable in $<$ then Poset-SAT($\Phi$) is the same problem as Temp-SAT($\Phi$). All temporal constraint satisfaction problems are classified in [6].

- **Example 3.** Let every formula $\phi(x_1, \ldots, x_n)$ in $\Phi$ be a $\leq$-Horn formula, that is a formula of the form

  $$
  x_{i_1} \leq x_{j_1} \land x_{i_2} \leq x_{j_2} \land \cdots \land x_{i_k} \leq x_{j_k} \rightarrow (x_{i_{k+1}} \leq x_{j_{k+1}} \lor \text{false})
  $$

  All problems of this “Horn-type” are tractable. One can see this by giving an algorithm based on the resolution rule. We discuss this class of tractable problems in Section 5.1.

- **Example 4.** We define $\text{Cycl}(x, y, z)$ by

  $$
  \text{Cycl}(x, y, z) := (x < y \land y < z) \lor (z < x \land x < y) \lor (y < z \land z < x) \lor (x < y \land z < x) \lor (y < z \land x < y) \lor (z < x \land y < x) \lor (z < x \land y < x).
  $$

  We will see in Section 5 that Poset-SAT($\{\text{Cycl}\}$) is an NP-complete problem.

  Every problem Poset-SAT($\Phi$) is clearly in NP. We can “guess” a partial order on the variables $x_1, \ldots, x_n$ and then checks in polynomial time if this partial order is a solution to the input formulas in $\Psi$ or not. The main result of this paper is to give a full classification of the computational complexity, showing the following dichotomy:

  **Theorem 5.** Let $\Phi$ be a finite set of quantifier-free $\leq$-formulas. The problem Poset-SAT($\Phi$) is in $P$ or NP-complete.
2.2 Poset-SAT(\(\Phi\)) as CSP

In this section we are going to show that every Poset-SAT problem can be translated into a constraint satisfaction problem or CSP over an infinite domain. This reformulation will allow us the use of universal-algebraic and Ramsey-theoretical methods.

Let \(\Gamma\) be a relational structure with signature \(\tau = \{R_1, R_2, \ldots\}\), i.e. \(\Gamma = (D; R^1_1, R^2_1, \ldots)\) where \(D\) is the domain of \(\Gamma\) and \(R^i_k \subseteq D^k\) is a relation of arity \(k\) over \(D\). When \(\Delta\) and \(\Gamma\) are two \(\tau\)-structures, then a homomorphism from \(\Delta\) to \(\Gamma\) is a mapping \(h\) from the domain of \(\Delta\) to the domain of \(\Gamma\) such that for all \(R \in \tau\) and for all \((x_1, \ldots, x_j) \in R^\Delta\) we have \(h(x_1, \ldots, x_j) \in R^\Gamma\). Injective homomorphisms that also preserve the complement of each relation are called embeddings. Bijective embeddings from \(\Delta\) onto itself are called automorphisms of \(\Delta\).

Suppose that the signature \(\tau\) of \(\Gamma\) is finite. Then the constraint satisfaction problem CSP(\(\Gamma\)) is the following decision problem:

\[
\text{CSP}(\Gamma): \quad \text{INSTANCE: A finite \(\tau\)-structure \(\Delta\)} \\
\text{QUESTION: Is there a homomorphism from \(\Delta\) to \(\Gamma\)?}
\]

We say that \(\Gamma\) is the template of the constraint satisfaction problem CSP(\(\Gamma\)).

We now need some terminology from model theory. Let \(\tau\) be a relational structure with domain \(D\). We say a relation \(R \subseteq D^n\) is definable in \(\Delta\), if there is a first order formula \(\phi\) in the signature of \(\Delta\) with free variables \((x_1, \ldots, x_n)\) such that \((a_1, \ldots, a_n) \in R\) if and only if \(\phi(a_1, \ldots, a_n)\) holds in \(\Delta\). A relational structure \(\Gamma\) with the same domain as \(\Delta\) is called a reduct of \(\Delta\) if all relations of \(\Gamma\) are definable in \(\Delta\).

A structure is called homogeneous if every isomorphism between finitely generated substructures can be extended to an automorphism of the whole structure.

Let \(C\) be a class of relational structures of the same signature. We say \(C\) has the amalgamation property if for every \(A, B, C \in C\) and all embeddings \(u : A \to B\) and \(v : A \to C\) there is a \(D \in C\) with embeddings \(u' : B \to D\), \(v' : C \to D\) such that \(u' \circ u = v' \circ v\). A class \(C\) is called an amalgamation class if it has the amalgamation property and is closed under isomorphism and taking induced substructures.

\textbf{Theorem 6} (Fraïssé, see Theorem 7.1.2 in [14]). Let \(C\) be an amalgamation class that has only countably many non-isomorphic members. Then there is a countable homogeneous structure \(\Gamma\) such that \(C\) is the age of \(\Gamma\), i.e. the class of all structures that embeds into \(\Gamma\). The structure \(\Gamma\), which is unique up to isomorphism, is called the Fraïssé limit of \(\Gamma\). \(\Box\)

Since the class of all finite partial orders forms an amalgamation class, it has a Fraïssé limit which is called the random partial order or random poset \(\mathbb{P} = (P; \leq)\). The random poset is a well-studied object in model theory that has a lot of helpful properties. As a homogenous structure in a finite relational language \(\mathbb{P}\) has quantifier-elimination, i.e. every formula in \(\mathbb{P}\) is equivalent to a quantifier-free formula. Also it is \(\omega\)-categorical, i.e. all countable structures that satisfy the same first order formulas as \(\mathbb{P}\) are isomorphic to \(\mathbb{P}\). Reducts of \(\omega\)-categorical structures are \(\omega\)-categorical as well. Therefore \(\mathbb{P}\) and all of its reducts are \(\omega\)-categorical. For further model-theoretic background on \(\omega\)-categorical and homogeneous structures we refer to [14].

Now let \(\Phi = \{\phi_1, \ldots, \phi_n\}\) be a finite set of quantifier free \(\leq\)-formulas. We associate with \(\Phi\) the \(\tau\)-structure \(\mathbb{P}_\Phi = (P; R_1, \ldots, R_n)\) that we obtain by setting \((a_1, \ldots, a_k) \in R_i\) if and
only if \( \phi_i(a_1, \ldots, a_k) \) holds in \( \mathcal{P} \). We claim that \( \text{CSP}(\Gamma_\Phi) \) and \( \text{Poset-SAT}(\Phi) \) are essentially the same problem. Let \( \Psi \) be an instance of \( \text{Poset-SAT}(\Phi) \) with the variables \( x_1, \ldots, x_n \). Then we define a structure \( \Delta_\Psi \) with domain \( \{x_1, \ldots, x_n\} \) as follows: The relation \( R^{\Delta_\Psi} \) contains the tuple \((x_1, \ldots, x_n)\) if and only if the instance \( \Phi \) contains the formula \( \phi_i(x_1, \ldots, x_n) \).

It is quite straightforward to see that \( \Psi \) is accepted by \( \text{Poset-SAT}(\Phi) \) if and only if \( \Delta_\Psi \) homomorphically maps to \( \mathcal{P}_\Phi \).

Conversely let \( \Gamma = (P; R_1, \ldots, R_n) \) be a reduct of \( \mathcal{P} \). Since \( \mathcal{P} \) has quantifier-elimination, every relation \( R_i \) in \( \Gamma \) has a quantifier-free definition \( \phi_i \) in \( \mathcal{P} \). With that in mind, we study the problem \( \text{Poset-SAT}(\{\phi_1, \ldots, \phi_n\}) \). Let \( \Delta \) be an instance of \( \text{CSP}(\Gamma) \). Then let \( \Psi_\Delta \) be an instance of \( \text{Poset-SAT}(\Phi) \) where the variables are the points in \( \Delta \) and \( \phi_i(x_1, \ldots, x_k) \in \Psi \) if and only if \((x_1, \ldots, x_k) \in R_i^{\Delta} \). Then \( \Delta \) is accepted by \( \text{CSP}(\Gamma) \) if and only if \( \Psi_\Delta \) is accepted by \( \text{Poset-SAT}(\Phi) \).

So by the observations in the paragraphs above the following holds:

\[ \text{Proposition 7. The problems of the form } \text{Poset-SAT}(\Phi) \text{ correspond precisely to the problems of the form } \text{CSP}(\Gamma), \text{ where } \Gamma \text{ is a reduct of the random partial order } \mathcal{P}. \quad \square \]

### 3. The universal-algebraic approach

We apply the so-called universal-algebraic approach and the Ramsey theoretical methods developed by Bodirsky and Pinsker in [10] to obtain our complexity results. Using the language of universal algebra we can elegantly describe the border between tractability and NP-hardness for CSPs on reducts of the random poset. In this section we give a brief introduction to this approach. For a more detailed introduction we refer to [3] as well as the shorter [21].

#### 3.1 Primitive positive definability

A first-order formula \( \phi(x_1, \ldots, x_n) \) in the language \( \tau \) is called primitive positive if it is of the form \( \exists y_1, \ldots, y_k \ (\psi_1 \land \cdots \land \psi_m) \) where \( \psi_1, \ldots, \psi_m \) are atomic \( \tau \)-formulas with free variables from the set \( \{x_1, \ldots, x_n, y_1, \ldots, y_k\} \).

Let \( \Gamma \) be a \( \tau \)-structure. We then say a relation \( R \) is is \( \text{primitively positive definable or pp-definable} \) in \( \Gamma \) if there is a primitive positive formula \( \phi(x_1, \ldots, x_n) \) such that \((a_1, \ldots, a_n) \in R \) if and only if \( \phi(a_1, \ldots, a_n) \) holds in \( \Gamma \).

\[ \text{Lemma 8 (Jeavons [15])}. \text{ Let } \Gamma \text{ be a relational structure in finite language, and let } \Gamma' \text{ be the structure obtained from } \Gamma \text{ by adding a relation } R. \text{ If } R \text{ is primitive positive definable in } \Gamma, \text{ then } \text{CSP}(\Gamma) \text{ and } \text{CSP}(\Gamma') \text{ are polynomial-time equivalent}. \quad \square \]

By \( \langle \Gamma \rangle_{pp} \) we denote the set of all primitively positive definable relations on \( \Gamma \). So for two structures \( \Gamma \) and \( \Delta \) the problems \( \text{CSP}(\Gamma) \) and \( \text{CSP}(\Delta) \) have the same complexity if \( \langle \Gamma \rangle_{pp} = \langle \Delta \rangle_{pp} \). This means that in our analysis we only have to study reduct of the random poset up to primitive positive definability.

#### 3.2 Polymorphism clones

Let \( \Gamma \) be a relational structure with domain \( D \). By \( \Gamma^n \) we denote the direct product of \( n \)-copies of \( \Gamma \). This is, we take a structure on \( D^n \) with same signature \( \Gamma \). Then for \( n \)-tuples \( \bar{x}^{(1)}, \ldots, \bar{x}^{(k)} \) we set that \( (\bar{x}^{(1)}, \ldots, \bar{x}^{(k)}) \in R \) if and only if \((x_1^{(1)}, \ldots, x_1^{(k)}) \in R \) holds in \( \Gamma \) for every coordinate \( i \in [n] \).
Then an $n$-ary operation $f$ is called a polymorphism of $\Gamma$ if $f$ is a homomorphism from $\Gamma^n$ to $\Gamma$. Unary polymorphisms are called endomorphisms. For every relation $R$ on $D$ we say $f$ preserves $R$ if $f$ is a polymorphism of $(D; R)$. Otherwise we say $f$ violates $R$.

For a given structure $\Gamma$ the set of all polymorphisms $\text{Pol}(\Gamma)$ contains all the projections $\pi_i^n(x_1, \ldots, x_n) = x_i$ and is closed under composition. Every set of operation with these properties is called a clone or function clone (cf. [24]). $\text{Pol}(\Gamma)$ is called the polymorphism clone of $\Gamma$. We write $\text{Pol}(\Gamma)^{(k)}$ for the set of $k$-ary functions in $\text{Pol}(\Gamma)$. We write $\text{End}(\Gamma)$ for the monoid consisting of all endomorphisms of $\Gamma$.

The clone $\text{Pol}(\Gamma)$ is furthermore locally closed in the following sense: Let $k > 1$ be arbitrary and let $f$ be a $k$-ary operation on $D$. If for every finite subset $A \subseteq D^k$ there is a $g \in \text{Pol}(\Gamma)$ with $g \rest A = f \rest A$ then also $f \in \text{Pol}(\Gamma)$.

For a set of operation $F$ on $D$ being locally closed is equal to be closed in the topology of pointwise convergence. We write $\overline{F}$ for smallest locally closed set containing $F$. We say a set of operation $F$ generates an operation $g$ if $g$ is in the smallest locally closed clone containing $F$.

It is of central importance to us that primitive positive definability in $\omega$-categorical (and finite) structures can be characterized by preservation under polymorphisms:

- **Theorem 9** (Bodirsky, Nešetřil [7]). Let $\Gamma$ be an $\omega$-categorical structure. Then a relation is pp-definable in $\Gamma$, if and only if it is preserved by the polymorphisms of $\Gamma$.

Then the complexity of $\text{CSP}(\Gamma)$ only depend on the polymorphism clone $\text{Pol}(\Gamma)$ for $\omega$-categorical $\Gamma$.

We also need the fact that a relation is not definable in $\Gamma$ can be described by polymorphisms of bounded arity.

- **Theorem 10** (Bodirsky, Kara [5]). Let $\Gamma$ be a relational structure and let $R$ be a $k$-ary relation that is a union of at most $m$ orbits of $\text{Aut}(\Gamma)$ on $D^k$. If $\Gamma$ has a polymorphism $f$ that violates $R$, then $\Gamma$ also has an at most $m$-ary polymorphism that violates $R$. ♦

### 3.3 Structural Ramsey theory

We apply Ramsey theory to analyse certain regular behaviour of polymorphisms. This approach was invented by Bodirsky and Pinsker and has been proven to be useful in several other classification results (e.g. [6], [10], [17]). We only give a brief introduction how Ramsey theory helps us to study polymorphism clones, a detailed introduction can be found in [8].

Let $\Gamma$ and $\Delta$ be two finite structures of the same signature. Then $\left( \frac{\Delta}{\Gamma} \right)$ denotes all the substructures of $\Delta$ that are isomorphic to $\Gamma$. We write $\Theta \rightarrow (\Delta)^{[k]}_{\kappa}$ if for every coloring $\kappa : \left( \frac{\Theta}{\Gamma} \right) \rightarrow [k]$ there is an isomorphic copy $\Delta'$ of $\Delta$ such that $\kappa$ is monochromatic on $\left( \frac{\Delta'}{\Gamma} \right)$.

Let $\mathcal{C}$ be a category of structures with the same signature that is closed under taking isomorphic copies and substructures. Then $\mathcal{C}$ is said to be a Ramsey class if for every $k \geq 1$ and every $\Gamma, \Delta \in \mathcal{C}$ there is a $\Theta \in \mathcal{C}$ such that $\Theta \rightarrow (\Delta)^{[k]}_{\kappa}$.

A homogeneous structure is said to be a homogeneous Ramsey structure if its age is a Ramsey class. A structure is called ordered, if it contains a total order relation.

If we look at the class of all structures $(A; \leq, \prec)$, where $\prec$ is a linear order that extends $\leq$, it has the Ramsey property and the amalgamation property (see [20]). Therefore its Fraïssé limit $(P; \leq, \prec)$ is an ordered homogeneous Ramsey structure.

- **Definition 11.** Let $\Gamma$ and $\Delta$ be two structures and $f$ an $n$-ary operation from the domain of $\Gamma$ to the domain of $\Delta$. Let $A$ be a subset of $\Gamma$. Then $f$ is called canonical on $A$, if for
every integer $s \geq 1$, all automorphisms $\alpha_1, \ldots, \alpha_n \in \text{Aut}(\Gamma)$ and tuples $d_1, \ldots, d_n \in A^s$ there is an automorphism $\beta \in \text{Aut}(\Delta)$ such that

$$f(\alpha_1(d_1), \ldots, \alpha_n(d_n)) = \beta(f(d_1, \ldots, d_n)).$$

If $f$ is canonical on the domain of $\Gamma$, we say that $f$ is canonical.

We remark that sometimes canonical functions are also defined as functions that preserve model-theoretic types. However, by the theorem of Ryll-Nardzewski, Engeler and Svenonius (confer [14]), the $s$-types of a countable $\omega$-categorical structure $\Gamma$ are exactly the orbits of $s$-tuples under the action of $\text{Aut}(\Gamma)$. Therefore the model theoretical definition is equivalent to the one we gave above, for $\omega$-categorical $\Gamma$ and $\Delta$. For this reason we are also going to use $(s)$-orbit and $(\sim)$-type synonymously.

Now Ramsey structures allows us to generate functions that are canonical on arbitrary large finite substructures of $\Gamma$ in the following sense:

\begin{itemize}
  \item \textbf{Theorem 12} (Lemma 19 in [8]). Let $\Gamma$ be an ordered homogeneous Ramsey structure with domain $D$ and let $f : D^l \to D$. Then for every finite subset $A$ of $\Gamma$ there are automorphisms $\alpha_1, \ldots, \alpha_l \in \text{Aut}(\Gamma)$ such that $f \circ (\alpha_1, \ldots, \alpha_l)$ is canonical on $A^l$. \hfill $\Box$
\end{itemize}

We can refine this statement by additionally fixing constants. Let $c_1, \ldots, c_n$ be elements of the domain of $\Gamma$. Then $(\Gamma, c_1, \ldots, c_n)$ denotes the structure that we obtain by extending $\Gamma$ by the constants $c_1, \ldots, c_n$.

\begin{itemize}
  \item \textbf{Theorem 13} (Lemma 27 in [8]). Let $\Gamma$ be an ordered homogeneous Ramsey structure with domain $D$. Let $c_1, \ldots, c_n \in D$ and $f : D^l \to D$. Then $\{f\} \cup \text{Aut}(\Gamma, c_1, \ldots, c_n)$ generates a function $g$ that is canonical as operation from $(\Gamma, c_1, \ldots, c_n)$ to $\Gamma$ and satisfies $f \restriction \{c_1, \ldots, c_n\} = g \restriction \{c_1, \ldots, c_n\}$. \hfill $\Box$
\end{itemize}

By the behaviour of a canonical function $f : \Delta \to \Lambda$ we denote the set of all tuples $(p, q)$ where $p$ is an $s$-type of $\Delta$, $q$ is a $s$-type of $\Lambda$ and for for every tuple $\bar{a}$ of type $p$ the image $f(\bar{a})$ has type $q$ in $\Lambda$. So we can regard the behaviour of a canonical function as a function from the types of $\Delta$ to the types of $\Lambda$. Let $A$ be a subset of the domain of $\Delta$. We call the behaviour of $f \restriction A$ the behaviour of $f$ on $A$. We say a function $f : \Delta \to \Lambda$ behaves like $g : \Delta \to \Lambda$ (on $A$) if their behaviour (on $A$) is equal.

### 3.4 Model-complete cores

Let $\Delta$ and $\Gamma$ be to structures with the same signature. We say $\Delta$ is homomorphically equivalent to $\Gamma$ if there is a homomorphisms from $\Delta$ to $\Gamma$ and a homomorphism from $\Gamma$ to $\Delta$. By definition, the constraint satisfaction problems CSP($\Delta$) and CSP($\Gamma$) encode the same computational problem for homomorphically equivalent structures $\Delta$ and $\Gamma$. By homomorphic equivalence we can find for every CSP a template with some nice model-theoretical properties.

A structure $\Delta$ is called a core if every endomorphism $e$ of $\Delta$ is a self embedding. A structure is called model-complete if every formula in its first order theory is equivalent to an existential formula. Note that endomorphisms preserve existential positive formulas, and embeddings preserve existential formulas. In the case of $\omega$-categorical structures also the opposite holds. Therefore we have:

\begin{itemize}
  \item \textbf{Lemma 14} (Lemma 13 in [9]). A countable $\omega$-categorical structure $\Gamma$ is a model-complete core if and only if the endomorphism monoid of $\Gamma$ is generated by $\text{Aut}(\Gamma)$. In this case, every definable relation in $\Gamma$ is also definable by existential positive formulas. \hfill $\Box$
\end{itemize}
Now every CSP with \( \omega \)-categorical template can be reformulated as a CSP on a template with model-complete core by the following theorem:

\[\text{Theorem 15 (Theorem 16 from [2]). Every } \omega \text{-categorical structure } \Gamma \text{ is homomorphically equivalent to a model-complete core which is unique up to isomorphism. This core is } \omega \text{-categorical or finite.} \]

So an important step in analyzing the complexity of CSP(\( \Gamma \)) is to identify the model-complete core of \( \Gamma \). By the following theorem of Bodirsky the complexity of the CSP of a core does not increase if we add finitely many constants.

\[\text{Theorem 16 (Theorem 19 from [2]). Let } \Gamma \text{ be a model-complete } \omega \text{-categorical or finite core, and let } c \text{ be an element of } \Gamma. \text{ Then CSP}(\Gamma) \text{ and } \text{CSP}(\Gamma, c) \text{ have the same complexity, up to polynomial time.} \]

### 3.5 Primitive positive interpretations

A tool to compare the complexity of CSPs of structures \( \Delta \) and \( \Gamma \) of possibly different domains and signatures are interpretations. We say \( \Delta \) is \emph{pp-interpretable} in \( \Gamma \) if there is a \( n \geq 1 \) and a partial map \( I : \Gamma^n \to \Delta \) such that

- \( I \) is surjective,
- the domain of \( I \) is pp-definable in \( \Gamma \),
- the preimage of the equality relation in \( \Delta \) is pp-definable in \( \Gamma \),
- the preimage of every relation in \( \Delta \) is pp-definable in \( \Gamma \).

Then the following result holds:

\[\text{Lemma 17 (Theorem 5.5.6 in [3]). If } \Delta \text{ is pp-interpretable in } \Gamma \text{ then CSP}(\Delta) \text{ can be reduced to CSP}(\Gamma) \text{ in polynomial time.} \]

The positive-1-in-3-SAT problem is a well-studied problem in literature that is known to be \( \text{NP-complete} \) [23]. It can be written as CSP(\( \{0, 1\}; 1\text{IN3} \)) with \( 1\text{IN3} := \{(1, 0, 0), (0, 1, 0), (0, 0, 1)\} \).

In practice we often show the \( \text{NP-completeness} \) of CSP(\( \Gamma \)) by finding a pp-interpretation of \( \text{(\( \{0, 1\}; 1\text{IN3}\))} \) in \( \Gamma \).

As pp-definability, also pp-interpretation can be translated into the language of clones.

A \emph{clone homomorphism} \( \xi : \text{Pol}(\Gamma) \to \text{Pol}(\Delta) \) is a map that preserves arities such that

- \( \xi(\pi^n_1) = \pi^n_1 \) for all projections,
- \( \xi(f \circ (g_1, \ldots, g_n)) = \xi(f) \circ (\xi(g_1), \ldots, \xi(g_n)) \).

For \( \omega \)-categorical or finite structures \( \Delta \) and \( \Gamma \) it is known that \( \Delta \) is pp-interpretable in \( \Gamma \) if and only if there exists a continuous clone homomorphism from \( \text{Pol}(\Gamma) \) onto \( \text{Pol}(\Delta) \).

\[\text{Theorem 18 (Bodirsky, Pinsker [11]). Let } \Gamma \text{ be finite or } \omega \text{-categorical and } \Delta \text{ be finite. Then } \Gamma \text{ has a primitive positive interpretation in } \Delta \text{ if and only if Pol}(\Gamma) \text{ has a continuous clone homomorphism to Pol}(\Delta). \]

The polymorphism clone of \( \text{(\( \{0, 1\}; 1\text{IN3}\))} \) consist only of the projections \( \pi^n_1 \) on the two element set \( \{0, 1\} \). We call it the \emph{projection clone} \( \mathbf{1} \). So \( \text{(\( \{0, 1\}; 1\text{IN3}\))} \) has a pp-interpretation in the \( \omega \)-categorical structure \( \Gamma \) if and only if there is a continuous clone homomorphism \( \xi : \text{Pol}(\Gamma) \to \mathbf{1} \). By Theorem 18 then \emph{every} finite structure \( \Delta \) has a pp-interpretation in \( \Gamma \), since it is easy to see that there is always a continuous clone homomorphism from \( \mathbf{1} \) to \( \text{Pol}(\Delta) \).

We summarize that for finite or \( \omega \)-categorical and finite structures \( \Delta \) and \( \Gamma \) the complexity of CSP(\( \Delta \)) reduces to CSP(\( \Gamma \)) in the following cases:
1. $\Delta$ is pp-interpretable in $\Gamma$.
2. $\Delta$ is the model-complete core of $\Gamma$.
3. $\Gamma$ is a model-complete core and $\Delta$ is obtained by adding finitely many constants to the signature of $\Gamma$.

By some recent results of Barto, Pinsker we can also express this fact nicely by polymorphism clones.

Theorem 19 (Theorem 1.4 in [22]). Let $\Gamma$ be finite or $\omega$-categorical and let $\Delta$ be its model-complete core. Then the following are equivalent:

1. Every finite structure has a pp-interpretation in some extension of $\Delta$ by finitely many constants.
2. There is a continuous clone homomorphism $\text{Pol}(\Delta,c_1,\ldots,c_n) \to \mathbf{1}$ for some constants $c_1,\ldots,c_n \in \Delta$.
3. There is a clone homomorphism $\text{Pol}(\Delta,c_1,\ldots,c_n) \to \mathbf{1}$ for some $c_1,\ldots,c_n \in \Delta$.
4. $\text{Pol}(\Delta)$ contains no pseudo-Siggers operation, i.e. a 6-ary operation $s$ such that $\alpha s(x,y,x,z,y,z) = \beta s(y,x,z,x,z,y)$ for some unary $\alpha,\beta \in \text{Pol}(\Delta)$. $\square$

Note that (4) shows that the question whether $(\{0,1\}; 1\text{IN}3)$ is pp-interpretable in any $(\Delta,c_1,\ldots,c_n)$ only depends on algebraic but not the topological properties of $\text{Pol}(\Delta)$.

4 A pre-classification by model-complete cores

In this section we start our analysis of reducts of the random partial order $P = (P; \leq)$. Our aim is to determine the model-complete core for every reduct $\Gamma$ of $P$. Therefore we are going to study all possible endomorphism monoids $\text{End}(\Gamma) \supseteq \text{Aut}(P)$. Part of the work was already done in [18] where all the automorphism groups $\text{Aut}(\Gamma) \supseteq \text{Aut}(P)$ were determined. Several parts of our proof are very similar to the group case; at that points we are going to directly refer to the corresponding proofs of [18].

If we turn the partial order $P$ upside-down, then the obtained partial order is again isomorphic to $P$. Hence there exists a bijection $\dashv: P \to P$ such that for all $x,y \in P$ we have $x < y$ if and only if $\dashv(y) < \dashv(x)$. By the homogeneity of $P$ it is easy to see that the monoid generated by $\dashv$ and $\text{Aut}(P)$ does not depend on the choice of the function $\dashv$.

The class of all finite structures $(A; \leq, F)$, where $(A; \leq)$ is a partial order and $F$ is upwards closed set is an amalgamation class. Its Fraïssé limit is isomorphic to $P$ with an additional unary relation $F$. We say $F$ is a random filter on $P$. Note that $F$ and $I = P \setminus F$ are both isomorphic to the random partial order. Furthermore for every pair $x \in I$ and $y \in F$ either $x < y$ or $x \perp y$ holds.

We define a new order relation $<_F$ on by setting $x <_F y$ if and only if

1. $x,y \in F$ and $x < y$ or,
2. $x,y \in I$ and $x < y$ or,
3. $x \in I$, $y \in F$ and $x \perp y$.

It is shown in [18] that the resulting structure $(P; <_F)$ is isomorphic to $(P, <)$. We fix a map $\odot_F: P \to P$ that maps $(P; <)$ isomorphically to $(P; <_F)$. By the homogeneity of $P$ one can see that the smallest closed monoid generated by $\odot$ and $\text{Aut}(P)$ does not depend on the choice of the random filter $F$. We fix a random filter $F$ and set $\odot := \odot_F$. 

CVIT 2016
For $B \subseteq \text{Sym}(P)$, let $\langle B \rangle$ denote the smallest closed subgroup of $\text{Sym}(P)$ containing $B$. For brevity, when it is clear we are discussing supergroups of $\text{Aut}(\mathcal{P})$, we may abuse notation and write $\langle B \rangle$ to mean $\langle B \cup \text{Aut}(\mathcal{P}) \rangle$.

**Theorem 20** (Theorem 1 from [13]). Let $\Gamma$ be a reduct of $\mathcal{P}$. Then $\text{Aut}(\Gamma) \supseteq \text{Aut}(\mathcal{P})$ is equal to one of the five groups $\text{Aut}(\mathcal{P}), \langle \downarrow \rangle, \langle \circ \rangle, \langle \downarrow, \circ \rangle$ or $\text{Sym}(P)$.

We are going to show the following extension of Theorem 20:

**Proposition 21.** Let $\Gamma$ be a reduct of $\mathcal{P}$. Then for $\text{End}(\Gamma)$ at least one of the following cases applies:

1. $\text{End}(\Gamma)$ contains a constant function,
2. $\text{End}(\Gamma)$ contains a function $g_\updownarrow$ that preserves $\updownarrow$ and maps $P$ onto a chain,
3. $\text{End}(\Gamma)$ contains a function $g_\perp$ that preserves $\perp$ and maps $P$ onto an antichain,
4. The automorphism group $\text{Aut}(\Gamma)$ is dense in $\text{End}(\Gamma)$, i.e. $\Gamma$ is a model-complete core. So by the classification in Theorem 20 $\text{End}(\Gamma)$ is the topological closure of $\text{Aut}(\mathcal{P}), \langle \downarrow \rangle, \langle \circ \rangle, \langle \downarrow, \circ \rangle$ or $\text{Sym}(P)$ in the space of all functions $P^P$.

Before we start with the proof Proposition 21 we want to point out its relevance for the complexity analysis of the CSPs on reducts of $\mathcal{P}$.

Constraint satisfaction problems on reducts of $(Q; <)$ are called temporal satisfaction problems. The CSPs on reducts of a countable set with a predicate for equality $(\omega; =)$ are called equality satisfaction problems. For both classes a full complexity dichotomy is known, see [6] and [5]. As a corollary of Proposition 21 we get the following pre-classification of CSPs reducing all the cases where $\Gamma$ is not a model-complete core to temporal or equality satisfaction problems:

**Corollary 22.** Let $\Gamma$ be a reduct of $\mathcal{P}$. Then one of the following holds

1. $\text{CSP}(\Gamma)$ is trivial;
2. The model-complete core of $\Gamma$ is a reduct of $(\omega; =)$, so $\text{CSP}(\Gamma)$ is equal to an equality satisfaction problem;
3. The model-complete core of $\Gamma$ is a reduct of $(Q; <)$, so $\text{CSP}(\Gamma)$ is equal to a temporal satisfaction problem;
4. $\text{End}(\Gamma)$ is the topological closure of $\text{Aut}(\mathcal{P}), \langle \downarrow \rangle, \langle \circ \rangle$ or $\langle \downarrow, \circ \rangle$.

**Proof.** If there is a constant function in $\text{End}(\Gamma)$, then $\text{CSP}(\Gamma)$ accepts every instance, so we are in the first case. So let $\text{End}(\Gamma)$ contain no constants.

Assume that $g_\perp \in \text{End}(\Gamma)$. Since $g_\perp$ preserves $\perp$, the image of $(P; \perp)$ under $g_\perp$ is isomorphic to a countable antichain, or in other word, a countable set $\omega$ with a predicate for inequality $(\omega; \neq)$. Thus, for every reduct of $\Gamma$ the image $g_\perp(\Gamma)$ can be seen as a reduct of $(\omega; \neq)$. Now clearly $\Gamma$ and $g_\perp(\Gamma)$ are homomorphically equivalent. It is shown in [6] that every reduct of $(\omega; \neq)$ without constant endomorphisms is a model-complete core. So we are in the second case.

Now assume that $g_\updownarrow \in \text{End}(\Gamma)$ but $g_\perp \notin \text{End}(\Gamma)$. Since $g_\updownarrow$ preserves $\updownarrow$ and is a chain, the image of $(P; \updownarrow)$ under $g_\updownarrow$ has to be isomorphic to the rational order $(\omega; \neq)$. Thus for every reduct of $\Gamma$ the image $g_\updownarrow(\Gamma)$ can be seen as a reduct of $\mathcal{Q}$. Now clearly $\Gamma$ and $g_\updownarrow(\Gamma)$ are homomorphically equivalent. It is shown in [6] that the model-complete core of every reduct of $(\mathcal{Q}, \updownarrow)$ is either trivial, definable in $(\omega, \neq)$ or the reduct itself. So we are in the third case.

Note that also in the case where $\text{End}(\Gamma) = \overline{\text{Sym}(\mathcal{P})}$ we have that $g_\perp \in \text{End}(\Gamma)$. So by Proposition 21 we are only left with the cases where $\text{End}(\Gamma)$ is the topological closure of $\text{Aut}(\mathcal{P}), \langle \downarrow \rangle, \langle \circ \rangle$ or $\langle \downarrow, \circ \rangle$. □
Let us define the following relations on $P$:

- $\text{Betw}(x, y, z) := (x < y \land y < z) \lor (z < y \land y < x)$.
- $\text{Cycl}(x, y, z) := (x < y \land y < z) \lor (y < z \land z < x) \lor (z < x \land x < y) \lor (x < y \land z < y) \lor (y < z \land x < y) \lor (z < x \land y < x)$.
- $\text{Par}(x, y, z) := (x < y \land y < z) \lor (y < z \land z < x) \lor (x < z \land y < z) \lor (y < z \land x < y) \lor (z < x \land y < x)$.
- $\text{Sep}(x, y, z, t) := (\text{Cycl}(x, y, z) \land \text{Cycl}(y, z, t) \land \text{Cycl}(x, y, t) \land \text{Cycl}(x, z, t)) \lor (\text{Cycl}(z, y, x) \land \text{Cycl}(y, t, z) \land \text{Cycl}(t, y, x) \land \text{Cycl}(t, z, x))$.

In Lemma 24 we are going to give a description of the monoids $\langle 3 \rangle$, $\langle 2 \rangle$ and $\langle 3, 2 \rangle$ as endomorphism monoids with the help of the above relations. We remark that Cycl and Par describes the orbits triples under $\langle 3 \rangle$ and Sep describes the orbit of a linearly ordered 4-tuple under $\langle 3, 2 \rangle$.

**Lemma 23.** The incomparability relation $\perp$ is pp-definable in $(P; <, \text{Cycl})$ and Par is pp-definable in $(P; \text{Cycl})$.

**Proof.** To prove the first part of the lemma, let

$$\psi(x, y, a, b, c, d) := x < a < c \land x < b < d \land y < c \land y < d \land \text{Cycl}(x, a, y) \land \text{Cycl}(x, b, y) \land \text{Cycl}(y, c, b) \land \text{Cycl}(y, d, a) \land \text{Cycl}(b, d, c) \land \text{Cycl}(a, c, d).$$

We claim that $x \perp y$ is equivalent to $\exists a, b, c, d \psi(x, y, a, b, c, d)$. It is not hard to verify that $x \perp y$ implies $\exists a, b, c, d \psi(x, y, a, b, c, d)$. For the other direction note that $\psi(x, y, a, b, c, d)$ implies that $x \neq y$ because $\text{Cycl}(x, a, y)$ is part of the conjunction $\psi$.

Let us assume that $x < y$ and $\psi(x, y, a, b, c, d)$ holds for some elements $a, b, c, d \in P$. Then $\text{Cycl}(x, a, y)$ implies that $a < y$, symmetrically we have $b < y$. Since $y < c$, $d$ we have that $a < d$ and $b < c$. Then $\text{Cycl}(b, d, c)$ implies $d < c$ and $\text{Cycl}(a, c, d)$ implies $c < d$, which is a contradiction.

Now assume that $y < x$ and $\psi(x, y, a, b, c, d)$ holds for some elements $a, b, c, d \in P$. Then we have $y < a, b$ by the transitivity of the order. Then $\text{Cycl}(y, c, b)$ implies $c < b$ and $\text{Cycl}(y, d, a)$ implies $d < a$. But this leads to the contradiction $a < c < b$ and $b < d < a$.

For the second part of the lemma let $s, t \in P$ be two elements with $s < t$. Then the set $X = \{x \in P : s < x < t\}$ is pp-definable in $(P; \text{Cycl}, s, t)$ by the formula $\phi(x) := \text{Cycl}(s, x, t)$. By a back-and-forth argument one can show the two structures $(X; \leq)$ and $(P; \leq)$ are isomorphic. The order relation, restricted to $X$ is also pp-definable in $(P; \text{Cycl}, s, t)$ by the equivalence

$$y <_{X} z \iff \phi(x) \land \phi(y) \land \text{Cycl}(y, z, t).$$

Since $\perp$ is pp-definable in $(P; <, \text{Cycl})$, we have that its restriction to $X$ has a pp-definition in $(P; \text{Cycl}, s, t)$. Therefore also the relation $R = \{ (x, y, z) \in X^3 : x \perp y \land x \perp z \land z \perp y \}$ is pp-definable in $(P; \text{Cycl}, s, t)$. Let $\phi(s, t, u, v, w)$ be a primitive positive formula defining $R$.

We claim that $\exists x, y \phi(x, y, u, v, w)$ is equivalent to $(u, v, w) \in \text{Par}$. Let $(u, v, w) \in \text{Par}$. The relation Par describes the orbit of a 3-element antichain under the action of $\langle 3 \rangle \subseteq \text{End}(P; \text{Cycl})$. So we can assume that $(u, v, w)$ is a 3-antichain, otherwise we take an image under a suitable function form $\langle 3 \rangle$. Now let us take elements $s < t$ such that $s < u w v$ and $u w w < t$. Then clearly $\psi(s, t, u, v, w)$ has to hold.

Conversely let $(s, t, u, v, w)$ be a tuple such that $\psi(s, t, u, v, w)$ holds. We can assume that $s < t$ (otherwise we take the image of $(s, t, u, v, w)$ under a suitable function in $\langle 3 \rangle$).

By what we proved above, $(u, v, w)$ is antichain, hence it satisfies Par. ▶
1. Clearly $\text{Aut}({\mathbb{P}}) \subseteq \text{End}(P; <, \perp)$. For the other inclusion let $f \in \text{End}(P; <, \perp)$. Let $A \subseteq P$ be an arbitrary finite set. The restriction of $f$ to a finite subset $A \subseteq P$ is an isomorphism between posets. By the homogeneity of $\mathbb{P}$ there is an automorphism $\alpha \in \text{Aut}(\mathbb{P})$ such that $f \restriction A = \alpha \restriction A$.

2. Since $\uparrow$ preserves Betw and $\perp$, we know that $\langle \langle \rangle \rangle \subseteq \text{End}(P; \text{Betw}, \perp)$ holds. For the opposite inclusion let $f \in \text{End}(P; \text{Betw}, \perp)$. If $f$ preserves $<$, then $f \in \text{End}(P; <, \perp)$ and we are done. Otherwise there is a pair of elements $c_1 < c_2$ with $f(c_1) > f(c_2)$. Let $d_1 < d_2$ be an other pair of points in $P$. Then there are $a_1, a_2 \in P$ such that $c_1 < d_2 < c_2 < a_1 < a_2$ and $d_1 < d_2 < a_1 < a_2$. Since $f$ preserves Betw, $f(a_1) > f(a_2)$ holds and hence also $f(d_1) > f(d_2)$. So $f$ inverts the order, while preserving $\perp$. Therefore $\uparrow \circ f \in \text{End}(P; <, \perp)$. We conclude that $f \in \langle \langle \rangle \rangle$.

3. It is easy to see that $\langle \langle \rangle \rangle \subseteq \text{End}(P; \text{Cycl})$. So let $f \in \text{End}(P; \text{Cycl})$. Clearly $f$ is injective and preserves also the relation $\text{Cycl}'(x, y, z) := \text{Cycl}(y, x, z)$. By Lemma 23, $f$ also preserves the relation Par. Furthermore $\langle \langle \rangle \rangle$ is 2-transitive: This can be verified by the fact that for every two elements of $P$, we can find a $\alpha \in \text{Aut}(\mathbb{P})$ that map one element to the random filter $F$ and the other element to $P \setminus F$. So also $\text{End}(P; \text{Cycl})$ is 2-transitive. It follows that $\text{End}(P; \text{Cycl})$ also preserves the negation of Cycl. In other words, $f$ is a self-embedding of $(P; \text{Cycl})$. So, when restricted to a finite $A \subseteq P$, $f$ is a partial isomorphism. By the results in [19] we know that $(P; \text{Cycl})$ is a homogeneous structure. Hence for every finite $A \subseteq P$ we find an automorphism $\alpha \in \text{Aut}(P; \text{Cycl}) = \langle \langle \rangle \rangle$ such that $f \restriction A = \alpha \restriction A$.

4. Let $f \in \text{End}(P; \text{Sep})$. We claim that either $f$ or $\uparrow \circ f$ preserves Cycl. If we can prove our claim we are done by (3). First of all note that $\text{Sep}(x, y, z, u)$ implies $\text{Cycl}(x, y, z) \leftrightarrow \text{Cycl}(y, z, u)$.

Without loss of generality let there be a elements $x, y, z \in P$ with $\text{Cycl}(x, y, z)$ and $\text{Cycl}(f(x), f(y), f(z))$, otherwise we look at $\uparrow \circ f$ instead of $f$. Let $(r, s, t)$ be arbitrary tuple satisfying Cycl. We can always find elements $a < b < c$ in $P$ that are incomparable with all entries of $(x, y, z)$ and $(r, s, t)$. Further we can choose elements $u, v \in P$ that are incomparable with $(a, b, c)$ such that $z < u < v$ and $\text{Sep}(x, y, z, u) \land \text{Sep}(y, z, u, v)$ holds. This can be done by a case distinction and is left to the reader. By construction we have

$$\text{Sep}(x, y, z, u) \land \text{Sep}(y, z, u, v) \land \text{Sep}(z, u, v, a) \land \text{Sep}(u, v, a, b) \land \text{Sep}(v, a, b, c).$$

So we have that $(f(x), f(y), f(z)) \in \text{Cycl}$ if and only if $(f(a), f(b), f(c)) \in \text{Cycl}$. Repeating the same argument for $(r, s, t)$ gives us that $(f(r), f(s), f(t)) \in \text{Cycl}$.

Recall that we obtain an ordered homogeneous Ramsey structure $(P; \leq, <)$ by taking the Fraïssé limit of the class of finite structures $(A; \leq, <)$, where $(A; \leq)$ is a partial order on $A$ and $<$ an extension of $< to a total order. We can regard this structure to be an extension of $\mathbb{P}$ by a total order. By Theorem 13 the following holds:
Lemma 25. Let \( f : P \to P \) and \( c_1, \ldots, c_n \in P \) be any points. Then there exists a function \( g : P \to P \) such that

1. \( g \in \text{Aut}(P) \cup \{f\} \).
2. \( g(c_i) = f(c_i) \) for \( i = 1, \ldots, n \).
3. Regarded as a function from \( (P; \leq, \prec, c) \) to \( (P; \leq) \), \( g \) is a canonical function.

Let \( \Gamma \) be a reduct of \( \mathbb{P} \). We are going to study all feasible behaviors of a canonical function \( f : (P; \leq, \prec, c) \to (P; \leq) \) when \( f \in \text{End}(\Gamma) \). Note that the behavior of such \( f \) only depends on the behavior on the 2-types because \( (P; \leq, \prec, c) \) is homogeneous and its signature contains at most 2-ary relation symbols. Since there are only finitely many 2-types, the study of all possible behaviors of such canonical functions is a combinatorial problem. We introduce the following notation:

Notation 26. Let \( A, B \) be definable subsets of \( \mathbb{P} \) and let \( \phi_1(x, y), \ldots, \phi_n(x, y) \) be formulas. We let \( p_{A, B, \phi_1, \ldots, \phi_n}(x, y) \) denote the (partial) type determined by the formula \( x \in A \land y \in B \land \phi_1(x, y) \land \ldots \land \phi_n(x, y) \). Using this notation, we can describe the 2-types of \( (P; \leq, \prec, c) \). They are all of the form \( p_{X, Y, \phi, \psi} = \{(a, b) \in P^2 : a \in X, b \in Y, \phi(a, b) \land \psi(a, b)\} \), where \( X \) and \( Y \) are 1-types, \( \phi \in \{=, <, >, \bot\} \) and \( \psi \in \{=, <, >\} \).

Let \( X, Y \) be two distinct infinite 1-types of \( (P; \leq, \prec, c) \). We write \( X \nleftarrow Y \) if there are pairs \( (x, y), (x', y') \in X \times Y \) with \( x < y \) and \( x' \nless y' \).

When it is convenient for us we will abuse notation and write \( \bar{c} \) to describe the set containing all entries of the tuple \( \bar{c} \).

Observation 27. The structure \( (P; \leq, \prec, \bar{c}) \) is a homogeneous structure. If \( X \) is an 1-type of \( (P; \leq, \prec, \bar{c}) \) with infinite elements, then \( (X; \leq, \prec) \) is isomorphic to \( (P; \leq, \prec) \) itself. This can be seen by a back-and-forth argument. Similarly, if \( X \) and \( Y \) are 1-types of \( (P; \leq, \prec, \bar{c}) \) with infinite elements such that \( X \nleftarrow Y \) holds, then \( X \cup Y \) is isomorphic to \( (P; \leq) \) with \( X \) being a random filter. If we define \( X \leq Y \iff \exists (x, y) \in X \times Y \ (x \leq y) \) we get a partial order on the 1-types of \( (P; \leq, \prec, \bar{c}) \) (confer Lemma 18 of \[13\]). But note that the 1-types of \( (P; \leq, \prec, \bar{c}) \) are not necessarily linearly ordered by \( \prec \): There can be infinite 1-types \( X, Y \) and \( (x, y), (x', y') \in X \times Y \) with \( x < y \), \( x \nless y \) and \( y' < x' \), \( x' \nless y' \).

In the following lemmas let \( \Gamma \) be always be a reduct of \( \mathbb{P} \) and let \( f \in \text{End}(\Gamma) \) be a canonical function from \( (P; \leq, \prec, \bar{c}) \) to \( (P; \leq) \).

Lemma 28. Let \( X \) be a 1-type of \( (P; \leq, \prec, \bar{c}) \) with infinite elements. Then \( f \) behaves like \( id \) or \( \nexists \) on \( X \), otherwise \( \text{End}(\Gamma) \) contains a constant function, \( g_\prec \) or \( g_\perp \).

Proof. Note that \( (X; \leq, \prec) \) is isomorphic to \( (P; \leq, \prec) \). Then we can prove the statement with the same arguments as in Lemma 8 of \[13\].

Lemma 29. Let \( X, Y \) two infinite 1-types of \( (P; \leq, \prec, \bar{c}) \) with \( X \nleftarrow Y \). Assume \( f \) behaves like \( id \) on \( X \). Then \( f \) behaves like \( id \) or \( \cup_X \) on \( X \cup Y \), otherwise \( \text{End}(\Gamma) \) contains a constant function, \( g_\prec \) or \( g_\perp \).

Proof. Assume that \( f \) does not contains a constant function, \( g_\prec \) or \( g_\perp \). Note that the union of \( X \) and \( Y \) is isomorphic to \( \mathbb{P} \) and \( X \) is a random filter of \( X \cup Y \). By following the arguments of Lemma 22 in \[13\] one can show that we only have the two possibilities that

1. \( f(p_{X, Y, \prec}) = p_\prec \) and \( f(p_{X, Y, \bot, \prec}) = p_\perp \) or
2. \( f(p_{X, Y, \prec}) = p_\perp \) and \( f(p_{X, Y, \bot, \prec}) = p_\succ \).
A complexity dichotomy for poset constraint satisfaction

By Lemma 28 we may assume that \( f \) behaves like \( \text{id} \) or \( \updownarrow \) on \( Y \). But if \( f \) behaves like \( \updownarrow \) on \( Y \), the image of \( y_1, y_2 \in Y \) and \( x \in X \) with \( x < y_1 \) and \( x < y_2 \) would be a non partially ordered set. So if the type \( p_{X,Y,\updownarrow} \) is empty, \( f \) behaves like \( \text{id} \) or \( \Cap_X \) on \( X \cup Y \) and we are done.

If \( p_{X,Y,\updownarrow} \) is not empty, there are \( x \in X \) and \( y \in Y \) with \( x \rhd y \). We claim that in this case \( f(p_{X,Y,\updownarrow}) = f(p_{X,Y,\downarrow}) \). We only prove this claim for (1), the proof for (2) is the same.

Assume that \( f(p_{X,Y,\updownarrow}) = p_{\Perp} \). Then let \( x' \in X \) be an element such that \( y < x' \) and \( x < x' \) and \( y \Cap x' \). The fact that such an element exists can be verified by checking that the extension of \( \{x, y\} \cup \Cap \) by such an element \( x' \) still lies in the age of \((P; \leq, \prec, \Cap)\). By our assumption we then have \( f(x) < f(x') < f(y) \), which contradicts to \( f(x) \downarrow f(y) \).

Now assume that \( f(p_{X,Y,\updownarrow}) = p_{\Perp} \). Then let \( x' \in X \) be such that \( x < y < x' \) and \( x < y \) and \( x' \Cap xy \). Again the fact that \( x' \) exists can be verified by the homogeneity of \((P; \leq, \prec, \Cap)\). Then \( f(x) < f(y) < f(x') \), which contradicts to \( f(x') \downarrow f(x') \).

\[ \text{Lemma 30.} \] Either \( f \) behaves like \( \text{id} \) or \( \updownarrow \) on every single 1-type or \( \text{End}(\Gamma) \) contains a constant function, \( g_{\Perp} \) or \( g_{\Cap} \).

\[ \text{Proof.} \] For every two infinite orbits \( X \times Y \) there is an infinite orbit \( Z \) with \( X \Perp Z \) and \( Z \Perp Y \). For every two infinite orbits \( X \cup Y \) there is an infinite orbit \( Z \) with \( X \Perp Z \) and \( Y \Perp Z \). So this statement holds by Lemma 28 (cf Lemma 23 of [18]).

\[ \text{Lemma 31.} \] Assume \( \text{End}(\Gamma) \) does not contain constant functions, \( g_{\Perp} \) or \( g_{\Cap} \). Then there is a \( g \in \{\cap, \cup\} \cap \text{End}(\Gamma) \) such that \( g \circ f \) is canonical from \((P; \leq, \prec, \Cap)\) to \((P; \leq)\) and behaves like \( \text{id} \) on every set \( \{P \cup \Cap\} \cup \{\Cap\} \), with \( c \in \Cap \).

\[ \text{Proof.} \] By Lemma 30 \( f \) behaves like \( \text{id} \) or \( \updownarrow \) on every infinite orbit. Without loss of generality we can assume that the first case holds, otherwise consider \( \downarrow \circ f \).

Let \( X \Perp Y \), \( Y \Perp Z \) and \( X \Perp Z \) or \( X \Perp Z \). If \( f \) behaves like \( \text{id} \) on \( X \cup Y \) and \( Y \cup Z \) it also has to behave like \( \text{id} \) on \( X \cup Z \); otherwise the image of a triple \( (x, y, z) \in X \times Y \times Z \) with \( x \times y \times z \) would not be partially ordered. Let \( X \Cap Y, Z \Cap Y, Z \Cap X \). Again, if \( f \) behaves like \( \text{id} \) on \( X \cup Y \) and \( Y \cup Z \) it also has to behave like \( \text{id} \) on \( X \cup Z \), otherwise we get a contradiction.

By Lemma 29 \( f \) either behaves like \( \text{id} \) or like \( \Cap_X \) on the union two orbits \( X \Perp Y \). In the second case \( \Cap \in \text{End}(\Gamma) \). The set \( A = \{x \in P : y \times x \} \forall y \in f(Y) \} \) is a union of orbits of \( \text{Aut}(P; \leq, \Cap) \) and a random filter of \( P \). So \( \Cap \circ f \) is canonical and behaves like \( \text{id} \) on \( X \cup Y \). Repeating this step finitely many times gives us a function \( g \in \{\cap, \cup\} \) such that \( g \circ f \) behaves like \( \text{id} \) on the union of infinite orbits, by the observations in the paragraph above.

It is only left to show that \( g \circ f \) behaves like \( \text{id} \) between a given constant \( c \in \Cap \) and an infinite orbit \( X \). Assume for example that \( c \Cap X \) and \( g \circ f(p_{c \Cap, X}) = p_{\Cap} \). Let \( A \subseteq P \) with \( a \in A \). By homogeneity of \( P \) we find an automorphism of \( P \) that maps \( a \) to \( c \) and all points that are greater than \( a \) to \( X \). If we then apply \( g \circ f \) and repeat this process at most \( |A| \)-times we can map \( A \) to an antichain. Thus \( g_{\Cap} \in \text{End}(\Gamma) \) which contradicts to our assumption.

Similarly all other cases where \( g \circ f \) does not behave like \( \text{id} \) between \( c \) and \( X \) contradict our assumptions. We leave the proof to the reader. Hence \( g \circ f \) behaves like \( \text{id} \) everywhere except on \( \Cap \).

Now we are ready to proof the main result of the section.

\[ \text{Proof of Proposition 24.} \] Let \( \Gamma \) be a reduct of \( P \) such that \( \text{End}(\Gamma) \) does not contain constant functions, \( g_{\Perp} \) or \( g_{\Cap} \). We show that then \( \text{End}(\Gamma) \) is equal to \( \text{Aut}(P; \leq, \Cap) \) or \( \{\cup, \Cap\} \).

First assume that End(Γ) contains a non injective function. This can be witnessed by constants \(c_1 \neq c_2\) and a function \(f \in \text{End}(\Gamma)\) with \(f(c_1) = f(c_2)\) that is canonical as function \(f : (P; \leq, \prec, c_1, c_2) \rightarrow (P; \leq)\). By Lemma 51 we can assume that \(f\) behaves like \(id\) everywhere except from \(c_1, c_2\). But this is not possible, since there is a point in \(a \in P\) with \(a \perp c_1\) but \(-(a \perp c_2)\). Since \(f(c_1) = f(c_2)\) either \(<\) or \(\perp\) is violated, which contradicts to \(f\) behaving like \(id\) everywhere except on \(\{c_1, c_2\}\). So from now on let End(Γ) only contain injective functions.

Assume End(Γ) violates Sep. This can also be witnessed by a canonical function \(f : (P; \leq, \prec, \bar{c}) \rightarrow (P; \leq)\) such that \(\bar{c} \in \text{Sep}\) but \(f(\bar{c}) \notin \text{Sep}\). By Lemma 51 we can assume that \(f\) behaves like \(id\) on every set \((P \setminus \bar{c}) \cup \{c\}\), with \(c \in \bar{c}\). If there are \(c_i < c_j\) with \(f(c_i) \perp f(c_j)\) it is easy to see that End(Γ) generates \(g_{\perp}\) which contradicts to our assumptions. If there are \(c_i < c_j\) or \(c_i \perp c_j\) with \(f(c_i) > f(c_j)\) let \(a\) be an element of \((P \setminus \bar{c})\) with \(a < c_j\) and \(a \perp c_i\). Then the image of \(a, c_i, c_j\) under \(f\) induces a non partially ordered structure - contradiction.

So End(Γ) preserves Sep. By Lemma 24 we know that End(Γ) \(\subseteq \langle \top, \bot \rangle\). If End(Γ) violates Cycl and Betw or Cycl and \(\perp\) we can prove as in the paragraph above that End(Γ) = \(\langle \top, \bot \rangle\).

Similarly, if End(Γ) preserves Cycl but violates Betw or \(\perp\) then End(Γ) = \(\langle \top \rangle\).

If End(Γ) preserves Betw and \(\perp\) but violates Cycl. Then End(Γ) = \(\langle \top \rangle\).

Finally, if End(Γ) preserves Betw, \(\perp\) and Cycl we have End(Γ) = Aut(\(\mathbb{P}\)).

\section{The case where \(<\) and \(\perp\) are pp-definable}

Throughout the remaining parts of this paper we are going to study the complexity of CSP(Γ) for model-complete reducts Γ of \(\mathbb{P}\). We start with the case where End(Γ) is the topological closure of the automorphism group of \(\mathbb{P}\). In this case the two relations \(<\) and \(\perp\) are pp-definable by Theorem 10. So throughout this section let Γ be a reduct of \(\mathbb{P}\) in which \(<\) and \(\perp\) are pp-definable. We are first going to discuss the binary part of the Pol(Γ). This will be essential for proving the dichotomy in this case.

\begin{observation}
The binary relation \(x \perp y\) defined by \(x < y \lor x \perp y\) is equivalent to the primitive positive formula \(\exists z \ (z < y) \land z \perp x\). Therefore \(x \perp y\) is pp definable in Γ.
\end{observation}

By \(e_<\) we denote an embedding of the structure \((P; <)^2\) into \((P; <)\). Clearly \(e_<\) is canonical when regarded as map \(e_< : (P; \leq, <)^2 \rightarrow (P; \leq)\). It has the following behaviour:

\[
\begin{array}{c|cccc}
\text{e<} & = & < & > & \bot \\
\hline
= & = & \bot & \bot & \bot \\
< & \bot & < & \bot & \bot \\
> & \bot & > & \bot & \bot \\
\bot & \bot & \bot & \bot & \bot
\end{array}
\]

By \(e_\leq\) we denote an embedding of \((P; \leq)^2\) into \((P; \leq)\) that is canonical function when regarded as map \(e_\leq : (P; \leq, \prec)^2 \rightarrow (P; \leq)\). It has the following behaviour:

\[
\begin{array}{c|cccc}
\text{e\leq} & = & < & > & \bot \\
\hline
= & = & < & > & \bot \\
< & < & < & \bot & \bot \\
> & > & > & \bot & \bot \\
\bot & \bot & \bot & \bot & \bot
\end{array}
\]
5.1 Horn tractable CSPs given by $e_<$ and $e_\leq$

The two functions $e_<$ or $e_\leq$ are of central interest to us. We will show in this section that if one of them is a polymorphisms of $\Gamma$, then the problem $\text{CSP}(\Gamma)$ is tractable.

Let $\Delta$ and $\Lambda$ be relational structures of the same signature. We say a map $h : \Delta \rightarrow \Lambda$ is a strong homomorphism if $x \in R \iff h(x) \in R$. By $\Delta$ we denote the extension of $\Delta$ that contains the negation $\neg R$ for every $R$ is in $\Delta$.

\[\text{Theorem 33 (Proposition 14 from \cite{4})}\] Let $\Delta$ be an $\omega$-categorical structure and let $\Gamma$ be a reduct of $\Delta$. Suppose $\text{CSP}(\Delta)$ is tractable. If $\Gamma$ has a polymorphism that is a strong homomorphism from $\Delta^2$ to $\Delta$, then also $\Gamma$ is tractable. \hfill $\Box$

By definition $e_<$ is a strong homomorphism from $(P; <)^2 \rightarrow (P; <)$ and $e_\leq$ a strong homomorphism from $(P; \leq)^2 \rightarrow (P; \leq)$. Let $\not< \text{ and } \not\leq$ denote the negation of the order relation $<$ respectively $\leq$. One can see that every input to $\text{CSP}(P; <, \not<)$ and $\text{CSP}(P; \leq, \not\leq)$ is accepted as long as it does not contradict to the transitivity of $<$ respectively $\leq$. But this can be checked in polynomial time, thus the two problems are tractable. So by Theorem 33 every template $\Gamma$ with polymorphism $e_<$ or $e_\leq$ gives us a tractable problem.

In the following theorem we additionally give a semantic characterization of these tractable problems via Horn formulas. This characterisation works also in the general setting, we refer to \cite{4} for the proof.

\[\text{Theorem 34. Let $\Gamma$ be a reduct of $\mathbb{P}$. Suppose that $e_\leq \in \text{Pol}(\Gamma)$. Then $\text{CSP}(\Gamma)$ is tractable and every relation in $\Gamma$ is equivalent to a Horn formula in $(P; \leq)$:}\]

\[
\begin{align*}
    x_{i_1} \leq x_{j_1} \land x_{i_2} \leq x_{j_2} \land \cdots \land x_{i_k} \leq x_{j_k} & \rightarrow x_{i_{k+1}} \leq x_{j_{k+1}} \quad \text{or} \\
    x_{i_1} \leq x_{j_1} \land x_{i_2} \leq x_{j_2} \land \cdots \land x_{i_k} \leq x_{j_k} & \rightarrow \text{false'}
\end{align*}
\]

Suppose that $e_< \in \text{Pol}(\Gamma)$. Then $\text{CSP}(\Gamma)$ is tractable and every relation in $\Gamma$ is equivalent to a Horn formula in $(P; <)$, i.e. a formula of the form:

\[
\begin{align*}
    x_{i_1} <_1 x_{j_1} \land x_{i_2} <_2 x_{j_2} \land \cdots \land x_{i_k} <_k x_{j_k} & \rightarrow x_{i_{k+1}} <_{k+1} x_{j_{k+1}} \quad \text{or} \\
    x_{i_1} <_1 x_{j_1} \land x_{i_2} <_2 x_{j_2} \land \cdots \land x_{i_k} <_k x_{j_k} & \rightarrow \text{false'}
\end{align*}
\]

where $<_i \in \{<, =\}$ for all $i = 1, \ldots, k + 1$. \hfill $\Box$

5.2 Canonical binary functions on $(P; \leq, <)$

A first step in analysing the binary part of $\text{Pol}(\Gamma)$ is to look at the special case of canonical functions. So in the following text we are going to study the behaviour of binary functions $f \in \text{Pol}(\Gamma)$ that are canonical seen as functions from $(P; \leq, <)^2$ to $(P; \leq)$. We are going to specify conditions for which $\text{Pol}(\Gamma)$ contains $e_<$ or $e_\leq$.

\[\text{Definition 35. Let } f : \mathbb{P}^2 \rightarrow \mathbb{P} \text{ be a function. Then } f \text{ is called dominated on the first argument if}\]

\[
\begin{align*}
    & f(x,y) < f(x',y') \text{ for all } x < x' \text{ and} \\
    & f(x,y) \perp f(x',y') \text{ for all } x \perp x'.
\end{align*}
\]

We say $f$ is dominated if $f$ or $(x,y) \mapsto f(y,x)$ is dominated on the first argument.

We are going to prove the following theorem:

\[\text{Theorem 36. Let $\Gamma$ be a reduct of $\mathbb{P}$ in which $<$ and $\perp$ are pp-definable. Let } f(x,y) \in \text{Pol}(\Gamma) \text{ be canonical when seen as a function from } (P; \leq, <)^2 \text{ to } (P; \leq). \text{ Then at least one of the following cases holds:}\]

\[
\begin{align*}
    & \text{Suppose that } f \text{ is dominated on the first argument.} \\
    & \text{Suppose that } f \text{ is not dominated on the first argument.}
\end{align*}
\]
\[ f \text{ is dominated} \]
\[ \text{Pol}(\Gamma) \text{ contains } e_\prec \]
\[ \text{Pol}(\Gamma) \text{ contains } e_\leq \]

First of all we make some general observations for binary canonical functions preserving \( \prec \) and \( \perp \). We are again going to use the notation introduced in Notation \[26\]. Let us fix a function \(- : (P; \leq, \prec) \to (P; \leq, \prec)\) such that \( x \prec y \Leftrightarrow -y \prec -x \) holds. It is easy to see that such a function exists.

\textbf{Lemma 37.} Let \( f : (P; \leq, \prec)^2 \to (P; \leq) \) be canonical and \( f \in \text{Pol}(\Gamma) \). Then the following statements are true:

1. \( f(p_\prec, p_\prec) = p_\prec \), \( f(p_\perp, p_\perp) = p_\perp \)
2. \( f(p, q) = -f(-p, -q) \), for all types \( p, q \).
3. \( f(p_\prec, p_\perp), f(p_\perp, p_\perp), f(p_\perp, p_\prec) \) and \( f(p_\prec, p_\prec) \) can only be equal to \( p_\prec \) or \( p_\perp \).
4. At least one of \( f(p_\prec, p_\perp) \) and \( f(p_\perp, p_\prec) \) is equal to \( p_\perp \).
5. At least one of \( f(p_\prec, p_\perp, p_\perp) \) and \( f(p_\perp, p_\prec, p_\prec) \) is equal to \( p_\perp \).
6. It is not possible that \( f(p_\prec, p_\prec) = p_\perp \) holds.
7. \( f(p_\perp, p_\prec) = p_\perp \to f(p_\perp, p_\perp) = p_\perp \)

\textbf{Proof.}

1. This is clear, since \( f \) is a polymorphism of \( \Gamma \) and hence preserves \( \prec \) and \( \perp \).
2. This is true by definition of \(-\).
3. This is true since \( f \) preserves the relation \( \frac{1}{\prec} \), see Observation \[32\].
4. Assume \( f(p_\prec, p_\perp) = f(p_\perp, p_\prec) = p_\prec \). Let \( a_1 \prec a_2 \prec a_3 \) with \( a_1 < a_2, a_3 \perp a_2 a_2 \) and \( b_1 < b_2 < b_3 \) with \( b_2 < b_3, b_1 \perp b_2 b_3 \). By our assumption \( f(a_1, b_1) < f(a_2, b_2) < f(a_3, b_3) \) holds, which is a contradiction to \( f \) preserving \( \perp \).
5. This can be proven similarly to (4).
6. Assume that \( f(p_\prec, p_\prec) = p_\perp \) holds. Let \( a_1 \prec a_2 \prec a_3 \) with \( a_1 < a_3, a_2 < a_3, a_1 \perp a_2 \) and \( b_1 > b_2 > b_3 \) with \( b_1 > b_3, b_2 > b_3, b_1 \perp b_2 b_3 \). Then \( f(a_1, b_1), f(a_2, b_2) \) but also \( f(a_3, b_3) = f(a_2, a_2) \) have to hold, which is a contradiction.
7. Assume that there are \( a_1 \perp a_2 \) and \( b \) such that \( f(a_1, b) \leq f(a_2, b) \) holds. Then we take elements \( a_3 \) and \( b' \) with \( a_2 < a_3, a_1 \perp a_3 \) and \( a_1 \prec a_3 \) and \( b' > b \). Then \( f(a_1, b) \leq f(a_2, b) \) \( \not\leq f(a_3, b') \) holds, which is a contradiction to \( f(a_1, b) \perp f(a_3, b') \).

By Lemma \[37\] (2) we only have to consider pairs of types where the first entry is \( p_\prec \), \( p_\perp \) or \( p_\perp, \prec \) when studying the behaviour of \( f \). Further Lemma \[37\] implies that \( f(x, y) \neq f(x', y') \) always holds for \( x \neq x' \) and \( y \neq y' \).

\textbf{Lemma 38.} Let \( f \in \text{Pol}(\Gamma) \). Then the following are equivalent:

1. \( f(p_\prec, p_\perp) = p_\prec \)
2. \( f(p_\prec, p_\perp) = p_\prec \)
3. \( f(p_\prec, q) = p_\prec \) for all 2-types \( q \)
4. \( f \) is dominated in the first argument

\textbf{Proof.} It is clear that the implications (4) \( \to \) (3) \( \to \) (2) and (3) \( \to \) (1) are true.

(1) \( \to \) (3): Let \( a_1 < a_2 < a_3 \) and \( b_1 b_3 < b_2 \). Then \( f(a_1, b_1) < f(a_2, b_2) < f(a_3, b_3) \) has to hold regardless if the type of \( (b_1, b_3) \) is \( p_\prec, p_\perp, p_\perp \). So \( f(p_\prec, q) = p_\prec \) for all 2-types \( q \).

(2) \( \to \) (1): Let \( a_1 < a_2 < a_3 \) and \( b_1 > b_2 > b_3 \) with \( b_1 > b_3, b_2 \perp b_1 b_3 \). Then \( f(a_1, b_1) < f(a_2, b_2) < f(a_3, b_3) \) implies \( f(a_1, b_1) < f(a_3, b_3) \) and so \( f(p_\prec, p_\perp) = p_\prec \).
A complexity dichotomy for poset constraint satisfaction

(3) → (4): We have to consider all the pairs of 2-types where the first entry is \( p_{\perp, 3} \). By Lemma \[37\] (4) and (5) we know that \( f(p_{\perp, 3}, p_{\perp, 3}) = f(p_{\perp, 3}, p_{\perp, 3}) = p_{\perp} \). From Lemma \[37\] (7) follows that \( f(p_{\perp, 3}, p_{\perp, 3}) = p_{\perp} \).

We want to point out that we did not require \( f \) to be canonical; it can be easily verified that all proof steps also work for general binary functions.

\[\textbf{Lemma 39.} \text{Let } f : (P; \leq, \prec)^2 \to (P; \leq) \text{ be canonical and } f \in \text{Pol}(\Gamma). \text{ If } f \text{ is not dominated the following statements are true:} \]

\begin{enumerate}
\item \( f(p_{\perp, 3}, p_{\perp, 3}) = f(p_{\perp, 3}, p_{\perp, 3}) = f(p_{\perp, 3}, p_{\perp, 3}) = f(p_{\perp, 3}, p_{\perp, 3}) = p_{\perp} \).
\item \( f(p_{\perp, 3}, p_{\perp, 3}) = p_{\perp} \) or \( f(p_{\perp, 3}, p_{\perp, 3}) = p_{\perp} \).
\item \( f(p_{\perp, 3}, p_{\perp, 3}) = p_{\perp} \) or \( f(p_{\perp, 3}, p_{\perp, 3}) = p_{\perp} \).
\end{enumerate}

\[\textbf{Proof.} \]

1. is a direct consequence of Lemma \[37\]
2. Suppose there are \( a_1 < a_2 \) and \( b \) such that \( f(a_1, b) \geq f(a_2, b) \). Then we take elements \( a_3, b' \in P \) with \( a_2 \perp a_3, a_2 > a_3, a_1 < a_3 \) and \( b' > b \). Then \( f(a_2, b) \leq f(a_1, b) < f(a_3, b') \) holds, which is a contradiction to \( f(a_2, b), f(a_3, b') \).
3. Assume that there are \( a_1 \perp a_2, a_1 < a_2 \) and \( b \) such that \( f(a_1, b) \geq f(a_2, b) \). Then \( a_3, b' \) with \( a_2 > a_3, a_1 \perp a_3, a_1 = a_3 \) and \( b' < b \). Then \( f(a_2, b) > f(a_3, b') \) and \( f(a_1, b) \perp f(a_3, b') \). This contradicts to our assumption.

\[\textbf{Definition 40.} \text{Let us say a binary function is } \perp\text{-falling, if it has the same behaviour as } e_{3\perp} \text{ respectively } e_{\perp} \text{ on pairs of partial type } (p_{\perp}, p_{\perp}). \]

\[\textbf{Lemma 41.} \text{Let } f \in \text{Pol}(\Gamma) \text{ be a canonical function } f : (P; \leq, \prec)^2 \to (P; \leq) \text{ of } \perp\text{-falling behaviour. Then } \text{Pol}(\Gamma) \text{ contains } e_{\perp} \text{ or } e_{\perp}. \]

\[\textbf{Proof.} \text{From Lemma } \[37\] (7) follows that } f(p_{\perp, 3}, p_{\perp, 3}) = p_{\perp} \text{ and } f(p_{\perp, 3}, p_{\perp, 3}) = p_{\perp}. \text{ By Lemma } \[39\] we further know that } f(p_{\perp, 3}, p_{\perp, 3}) = p_{\perp}, f(p_{\perp, 3}, p_{\perp, 3}) = p_{\perp}. \text{ So we have to do a simple case distinction:} \]

- If \( f(p_{\perp, 3}, p_{\perp, 3}) = f(p_{\perp, 3}, p_{\perp, 3}) = p_{\perp} \), then } f \text{ behaves like } e_{\perp}, \text{ hence } e_{\perp} \in \text{Pol}(\Gamma).
- If \( f(p_{\perp, 3}, p_{\perp, 3}) = p_{\perp} \) and } f(p_{\perp, 3}, p_{\perp, 3}) = p_{\perp}, \text{ the function } (x, y) \to f((x, y), x) \text{ has the same behaviour as } e_{\perp}, \text{ thus } e_{\perp} \in \text{Pol}(\Gamma).
- Symmetrically if } f(p_{\perp, 3}, p_{\perp, 3}) = p_{\perp} \text{ and } f(p_{\perp, 3}, p_{\perp, 3}) = p_{\perp}, \text{ the function } (x, y) \to f((y, y), y) \text{ has the same behaviour as } e_{\perp}, \text{ thus } e_{\perp} \in \text{Pol}(\Gamma).
- If } f(p_{\perp, 3}, p_{\perp, 3}) = p_{\perp} \text{ and } f(p_{\perp, 3}, p_{\perp, 3}) = p_{\perp}, \text{ then } f \text{ has the same behaviour as } e_{\perp}, \text{ thus } e_{\perp} \in \text{Pol}(\Gamma).

We now give a simple criterion for the existence of a canonical } \perp\text{-falling function in } \text{Pol}(\Gamma). \text{ This criterium will allows us to finish the proof of Theorem } \[36\].

\[\textbf{Lemma 42.} \text{Assume that for every } k > 1, \text{ every pair of tuples } a, b \in P^k \text{ and every indices } \alpha, \beta \in [k] \text{ with } a_0 < a_0 \text{ and } \neg(b_0 \leq b_0) \text{ there exists a binary function } g \in \text{Pol}(\Gamma) \text{ such that } g(a_0, b_0) \perp g(a_0, b_0) \text{ and for all } i, j, \in [k]: \]

\begin{enumerate}
\item } a_i < a_j \text{ implies } g(a_i, b_i) < g(a_j, b_j) \text{ or } g(a_i, b_i) \perp g(a_j, b_j), \text{ } \text{ and } \text{ for all } i, j, \in [k]: \]
\item } a_i \perp a_j \text{ implies } g(a_i, b_i) \perp g(a_j, b_j), \text{ Then } \text{Pol}(\Gamma) \text{ contains } e_{\perp} \text{ and } e_{\perp}. \]
Proof. First we are going to show that for all $\bar{a}, \bar{b} \in P^k$ there is a binary function $f \in \text{Pol}(\Gamma)$ that has $\bot$-falling on $(\bar{a}, \bar{b})$. To be more precise we want to construct an $f \in \text{Pol}(\Gamma)$ such that:

- $f(a_i, b_j) < f(a_j, b_i)$ if $a_i < a_j$ and $b_i < b_j$,
- $f(a_i, b_i) \perp f(a_j, b_j)$ if $a_i < a_j$ and $(b_i \leq b_j)$,
- $f(a_i, b_i) \perp f(a_j, b_j)$ if $a_i, a_j$ and $b_i \neq b_j$.

We are going to construct $f$ by a recursive argument.

Let $f^{(0)}(x, y) = p^{(0)}(x, y) = x$ and $\bar{a}^{(0)} = f^{(0)}(\bar{a}, \bar{b})$. If already $f^{(0)}$ has the desired properties we set $f(x, y) = f^{(0)}(x, y)$ and are done.

Otherwise, in the $(k+1)$-th recursion step, we are given a function $f^{(k)}(x, y)$ and a tuple $\bar{a}^{(k)} = f^{(k)}(\bar{a}, \bar{b})$. Let us assume that there are indices $p, q$ with $a_p < a_q$, $(b_p \leq b_q)$ and $a^p_0 < a^q_0$. Then our assumption is that $g^{(k+1)}(x, y) \in \text{Pol}(\Gamma)$ such that $g^{(k+1)}(a^p_0, b_p) \perp g^{(k+1)}(a^q_0, b_q)$. We set $f^{(k+1)}(x, y) = g^{(k+1)}(f^{(k)}(x, y), y)$ and $\bar{a}^{(k)} = f^{(k)}(\bar{a}, \bar{b})$.

Note that by the properties (1) and (2) of the function $f^{(k)}$ the only possible cases for $f^{(k)}$ being not $\bot$-falling is the case above. It is clear that the recursion ends after finitely many steps.

So on every finite subset $X \times Y$ of $P^2$ we find a $\bot$-falling function. By a compactness argument there exists a $h \in \text{Pol}(\Gamma)$ that is $\bot$-falling on $P^2$. It remains to show that there is also a canonical $\bot$-falling function in $\text{Pol}(\Gamma)$.

By Theorem 12 we have that $h$ is canonical on arbitrarily large substructures of $P^2$. Let $(F_n)_{n \in \omega}$ be an increasing sequence of finite substructures such that its union is equal to $P$. Then for every $n \in \omega$ there are $\alpha_1^{(n)}, \alpha_2^{(n)} \in \text{Aut}(P)$ such that $f \circ (\alpha_1^{(n)}, \alpha_2^{(n)})$ is canonical on $F_n$. By thinning out the sequence we can assume that $f \circ (\alpha_1^{(n)}, \alpha_2^{(n)})$ has the same behaviour for every $n \in \omega$.

Since the behaviour $f \circ (\alpha_1^{(n)}, \alpha_2^{(n)})$ on all $F_n$ is the same, we can inductively pick automorphisms $h_n \in \text{Aut}(P)$ such that $h_n \circ f \circ (\alpha_1^{(n)}, \alpha_2^{(n)})$ agrees with $h_{n+1} \circ f \circ (\alpha_1^{(n+1)}, \alpha_2^{(n+1)})$ on $F_n$. The limit of this sequence is a canonical function in $\text{Pol}(\Gamma)$ with $\bot$-falling behaviour.

By Lemma 41 we have that $e_\prec$ or $e_\leq$ is an element of $\text{Pol}(\Gamma)$. This concludes the proof. £

**Proof of Theorem 36** Let $f : (P; \leq, \prec)^2 \rightarrow (P; \leq)$ be canonical and $f \in \text{Pol}(\Gamma)$. Let us assume that $f$ is not dominated. By Lemma 39 we know $f(p_\perp, p_\leq) = f(p_\perp, p_\perp, p_\leq) = f(p_\perp, p_\leq, p_\perp) = p_\perp$.

By Lemma 37 (3) and (4) we have to look at the following cases:

1. $f(p_\perp, p_\perp, p_\perp) = f(p_\perp, p_\perp, p_\perp) = p_\perp$.
2. $f(p_\perp, p_\perp, p_\perp) = p_\perp$ and $f(p_\perp, p_\perp, p_\perp) = p_\perp$.
3. $f(p_\perp, p_\perp, p_\perp) = p_\perp$ and $f(p_\perp, p_\perp, p_\perp) = p_\perp$.

In the first case $f$ has $\bot$-falling behaviour therefore we are done by Lemma 41.

For the remaining cases we can restrict ourselves to (2), otherwise we take $(x, y) \rightarrow f(y, x)$. From Lemma 37 (7) follows that $f(p_\perp, p_\perp) = p_\perp$. Thus $f(p_\perp, q) = p_\perp$ holds for every $2$-type $q$.

We are going to show that then the conditions in Lemma 42 are satisfied. Let $\bar{a}, \bar{b} \in P^k$ be two tuples of arbitrary length $k$ and let $p, q \in [k]$ such that $a_p < a_q$, $b_p < b_q$ and $b_p \perp b_q$ hold. Then let $\alpha \in \text{Aut}(\Gamma)$ with $\alpha(b_p) \supset \alpha(b_q)$. Such an automorphism exists by the homogeneity of $P$. Then we set $g(x, y) = f(x, \alpha(y))$.

Clearly $g(a_p, a_q) \perp g(b_p, b_q)$, since $\alpha(b_p) \supset \alpha(b_q)$. Also the other conditions in Lemma 42 are satisfied, by the properties of $f$. Therefore $\text{Pol}(\Gamma)$ contains $e_\prec$ or $e_\leq$. £
The NP-hardness of Low

Let Low be the 3-ary relation defined by

\[ \text{Low}(x,y,z) := (x < y \land z \perp xy) \lor (x < z \land y \perp xz) \]

Clearly \( \perp \) and \( < \) are pp-definable in Low. Note that Low is not preserved by \( e_\perp \) or \( e_\leq \), so CSP(\( P; \text{Low} \)) is not covered by the tractability result in Theorem 34. In this section we prove the NP-hardness of CSP(\( P; \text{Low} \)).

\textbf{Lemma 43.} Let us define the relations

\begin{align*}
\text{Abv}(x,y,z) &:= (y < x \land xy \perp z) \lor (z < x \land xz \perp y) \\
U(x,y,z) &:= (y < x \lor z < x) \land (y \perp z)
\end{align*}

Then Abv and U are pp-definable in Low.

\textbf{Proof.} Note that the formula

\[ \phi(x,y,z,v) := \exists u \ u \perp v \land \text{Low}(u,y,z) \land \text{Low}(y,x,v) \land \text{Low}(z,x,v) \]

is equivalent to the statement that \( v \perp x \) and \( y \perp z \) and at least one element of \( \{y,z\} \) is smaller than \( x \) and at most one element of \( \{y,z\} \) is smaller than \( v \)

With that in mind one can see that

\[ \exists v_1,v_2 \ \phi(x,y,z,v_1) \land \phi(v_2,y,z,x) \]

is equivalent to Abv(\( x,y,z \)) and

\[ \exists v \ \phi(x,y,z,v) \]

is equivalent to U(\( x,y,z \)). \hfill \Box

\textbf{Theorem 44.} Let \( a,b \in P \) with \( a \perp b \). There is a pp-interpretation of \( (\{0,1\};1\mathrm{IN}3) \) in \( (P;\text{Low},a,b) \). Thus CSP(\( P; \text{Low} \)) is NP-hard.

\textbf{Proof.} Let NAE be the Boolean relation \( \{0,1\}^3 \setminus \{(0,0,0),(1,1,1)\} \). It is easy to see that \( \text{Pol}(\{(0,1)\},\text{NAE},0,1) \) is the projection clone I. So by Theorem 19 it suffices to show that \( (\{0,1\};\text{NAE},0,1) \) has a pp-interpretation in \( (P;\text{Low},a,b) \) to prove the Lemma.

Let \( D := \{x \in P : \text{Low}(x,a,b)\} \), \( D_0 := \{x \in D : x < a\} \), \( D_1 := \{x \in D : x < b\} \). Note that \( D_0 \perp D_1 \). Let \( I : D \to \{0,1\} \) be given by:

\[ I(x) := \begin{cases} 0 & \text{if } x \in D_0 \\ 1 & \text{if } x \in D_1 \end{cases} \]

Clearly the domain \( D \) of \( I \) is pp-definable in \( (P;\text{Low},a,b) \). Since the order relation \( < \) is pp-definable in Low also the sets \( D_0 \) and \( D_1 \) are pp-definable. Let \( R = \{(x,y,z,t) \in P^4 : (x \lor y \lor x \lor z \lor x > t) \land \neg (x \leq yzt)\} \). We claim that the relation \( R \) is pp-definable in Low. Observe that \( (x,y,z,t) \in R \) is equivalent to

\[ \exists u,v \ \text{Abv}(x,u,v) \land U(x,y,u) \land U(x,z,u) \land U(x,t,v) \]

and therefore pp-definable in Low by Lemma 43. By the definition of \( R \) we have that \( I(c_1,c_2,c_3) \in \text{NAE} \) if and only if \( (a,c_1,c_2,c_3) \in R \) and \( (b,c_1,c_2,c_3) \in R \). Thus the preimage of \( \text{NAE} \) is pp-definable in \( (P;\text{Low},a,b) \). \hfill \Box
The following lemma gives us an additional characterization of reducts, in which \( \text{Low} \) is pp-definable.

**Lemma 45.** The relation \( \text{Low} \) is pp-definable in \( \Gamma \) if and only if every binary polymorphism of \( \Gamma \) is dominated.

**Proof.** Every dominated function \( f : P^2 \to P \) preserves \( \text{Low} \). For the other direction observe that by Lemma 38 we have that \( f \) is dominated in the first argument if and only if \( f(a_1, b_1) < f(a_2, b_2) \) for all \( a_1 < a_2 \) and \( b_1 \perp b_2 \). Note that Lemma 38 also works for non-canonical functions.

So if \( f \in \text{Pol}(\Gamma) \) is a binary, not dominated function, there are \( a_1 < a_2, b_1 \perp b_2, a'_1 \perp a'_2 \) and \( b'_1 < b'_2 \) such that \( f(a_1, b_1) \perp f(a_2, b_2) \) and \( f(a'_1, b'_1) \perp f(a'_2, b'_2) \). Hence \( f \) violates the relation

\[
S(x_1, x_2, y_1, y_2) := (x_1 < x_2 \land y_1 \perp y_2) \lor (x_1 \perp x_2 \land y_1 < y_2).
\]

But the relation \( S \) and \( \text{Low} \) are pp-interdefinable:

\[
\text{Low}(x, y, z) \leftrightarrow S(x, y, z) \land y \perp z
\]

\[
S(x_1, x_2, y_1, y_2) \leftrightarrow \exists u, v, w \ (\text{Low}(x_1, x_2, u) \land \text{Abv}(u, x_1, v),
\text{Low}(u, v, w) \land \text{Abv}(w, y_1, v) \land \text{Low}(y_1, y_2, w)).
\]

We conclude that \( f \) violates \( \text{Low} \).

---

**7 Violating the Low relation**

We saw in Theorem 34 that \( \text{CSP}(\Gamma) \) is tractable if \( e_\prec \) or \( e_\perp \) are polymorphisms of \( \Gamma \). By Theorem 43 we know that \( \text{CSP}(\Gamma) \) is NP-complete if \( \text{Low} \) is pp-definable in \( \Gamma \). In this section we are going to show that these results already cover all possible reducts where \( \prec \) and \( \perp \) are pp-definable.

**Theorem 46.** Let \( \Gamma \) be a reduct of \( \mathbb{P} \) such that \( \perp \) and \( \prec \) are pp-definable in \( \Gamma \). Then \( \text{Low} \) is not pp-definable in \( \Gamma \) if and only if \( \text{Pol}(\Gamma) \) contains one of the functions \( e_\prec \) or \( e_\perp \).

**Proof.** Note that by Theorem 10 Low is not pp-definable in \( \Gamma \) if and only if there is a binary \( f \in \text{Pol}(\Gamma) \) violating Low. This means that there are \( a, b, c \in P \) such that \( a < b \land ab \perp c \) and \( f(a, a) < f(b, c) \land f(a, a) < f(c, b), \) or \( f(a, a) \perp f(b, c) \) and \( f(a, a) \perp f(c, b) \).

We have only these two cases since \( f \) preserves \( \perp \) and \( \prec \). We can assume that \( a < b < c \) since otherwise we can find an automorphism \( \alpha \in \text{Aut}(\mathbb{P}) \) such that \( \alpha(a) < \alpha(b) < \alpha(c) \). Then we consider the map \( (x, y) \mapsto f(\alpha^{-1}(x), \alpha^{-1}(y)) \) with three elements \( \alpha(a), \alpha(b) \) and \( \alpha(c) \) instead.

By Theorem 13 we can assume that \( f \) is canonical as a function from \( (P; \prec, \perp, a, b, c)^2 \) to \( (P; <) \). We deal with the two cases in Lemma 48 and Lemma 55 in the following subsections.

**Notation 47.** For simplicities sake, a canonical binary function in this section means a function that is canonical as a function from \((P; \leq, \prec)^2 \to (P; <)\).

Let \( f : P^2 \to P \) be a function and \( X, Y, X', Y' \) be subsets of \( P \) such that \( f \) is dominated on \( X \times Y \) and \( X' \times Y' \). We say that \( f \) has the same domination on \( X \times Y \) and \( X' \times Y' \) if \( f \) is dominated by the first argument on both \( X \times Y \) and \( X' \times Y' \), or dominated by the second argument on both \( X \times Y \) and \( X' \times Y' \). Otherwise, we say that \( f \) has the different domination on \( X \times Y \) and \( X' \times Y' \).
23:22  A complexity dichotomy for poset constraint satisfaction

7.1  \( f(a, a) < f(b, c) \land f(a, a) < f(c, b) \)

The aim of this subsection is to prove the following lemma.

- **Lemma 48.** Let \( f \in \text{Pol}(\Gamma) \) be canonical as a function from \((P; <, \prec, a, b, c)^2\) to \((P; <)\). If \( f(a, a) < f(b, c) \land f(a, a) < f(c, b) \) then \( \text{Pol}(\Gamma) \) contains \( e_\prec \) or \( e_\preceq \).

We define the following two sets:

- \( B_1 := \{ x \in P : x > c \land x \perp a \land x \preceq b \} \),
- \( B_2 := \{ x \in P : x > b \land x > c \} \).

Let \( x, y \in B_1 \cup B_2 \). We say that \( x \) and \( y \) are in the same orbit if \( x \in B_i \) and \( y \in B_i \) for an \( i \in [2] \).

- **Observation 49.** \( B_1 \) and \( B_2 \) are orbits of \( \text{Aut}(P; \prec, \perp, a, b, c) \). By the homogeneity of \((P; \preceq, \prec)\) we can show that \((B_1; \preceq, \prec)\) and \((B_2; \preceq, \prec)\) are isomorphic to \((P; \preceq, \prec)\). Further also the union of \( B_1 \) and \( B_2 \) is an isomorphic copy of \((P; \preceq, \prec)\), in which \( B_i \) forms a random filter.

If there is a canonical \( g \in \text{Pol}(\Gamma) \) that is not dominated, then Lemma 36 gives us that \( e_\prec \) or \( e_\preceq \) is in \( \text{Pol}(\Gamma) \). So throughout the lemmata and corollaries below this section, we assume that every binary canonical function in \( \text{Pol}(\Gamma) \) is dominated and \( f(a, a) < f(b, c) \land f(a, a) < f(c, b) \).

- **Lemma 50.** \( f \) is dominated on \( B_i \times B_j \) for every \( i, j \in [2] \).

**Proof.** For a contradiction, we assume that \( f \) is not dominated on \( B_i \times B_j \). Since \((B_i; \preceq, \prec)\) and \((B_j; \preceq, \prec)\) are isomorphic to \((P; \preceq, \prec)\), there are \( \alpha : P \to B_i \) and \( \beta : P \to B_j \) such that \( \alpha \) is an isomorphism from \((P; \preceq, \prec)\) to \((B_i; \preceq, \prec)\) and \( \beta \) is an isomorphism from \((P; \preceq, \prec)\) to \((B_j; \preceq, \prec)\). Let \( g : P^2 \to P \) be given by \( g(x, y) := f(\alpha(x), \beta(y)) \). It follows from Observation 49 that \( g \) is canonical and is not dominated, a contradiction.

- **Lemma 51.** \( f \) has the same domination on all sets \( B_i \times B_j \), \( i, j \in [2] \).

**Proof.** We claim that \( f \) has the same domination on \( B_1 \times B_k \) and \( B_2 \times B_k \) for any \( k \in [2] \). For a contradiction, we assume that \( f \) does not have the same domination \( B_1 \times B_k \) and \( B_2 \times B_k \). Without loss of generality we can assume that \( f \) is dominated by the first argument on \( B_1 \times B_k \) and dominated by the second argument on \( B_2 \times B_k \). Let \( x, y \in B_1, z, t \in B_2 \) be such that \( x < y \land y < z \land x \perp t \). Let \( x', y', z', t' \in B_k \) be such that \( x' \perp t' \land y' < z' \land z' < t' \). Since \( f \) is dominated by the first argument on \( B_1 \times B_k \), we have \( f(x, x') < f(y, y') \). Since \( f \) is dominated by the second argument on \( B_2 \times B_k \), we have \( f(z, z') < f(t, t') \). Since \( f \) preserves \( \prec \), we have \( f(y, y') < f(z, z') \). Thus \( f(x, x') < f(t, t') \), a contradiction to the fact that \( f \) preserves \( \perp \).

In the rest of this section, we assume that \( f \) is dominated by the first argument on \( B_i \times B_j \) for every \( i, j \in [2] \). The other case can be reduced to this case by considering the map \( (x, y) \to f(y, x) \).

- **Lemma 52.** Let \( u, v \in B_1 \) and \( u', v' \in B_2, v' \in B_1 \) be such that \( u < v \lor u \perp v \). Then \( f(u, u') \perp f(v, v') \).
We define the following sets.

The aim of this section is to prove the following.

Proof. First, we claim that \( f(u, u') > f(v, v') \lor f(u, u') \perp f(v, v') \). For a contradiction, we assume that \( f(u, u') \leq f(v, v') \). Since \( f \) preserves \(<\), we have \( f(c, b) < f(u, u') \). Therefore \( f(a, a) < f(c, b) < f(u, u') < f(v, v') \), a contradiction to the \( \perp \)-preservation of \( f \). Thus the claim follows.

The proof is completed by showing that \( f(u, u') > f(v, v') \) is impossible. For a contradiction, we assume that \( f(u, u') > f(v, v') \). Let \( s, t \in B_1 \) be such that \( s \perp t \land s < v \land u < t \). Let \( s', t' \in B_1 \cup B_2 \) be such that \( s' \perp t' \). By the domination of \( f \), we have \( f(s, s') < f(v, v') \land f(u, u') < f(t, t') \). It follows from \( f(u, u') > f(v, v') \), we have \( f(s, s') < f(t, t') \), a contradiction to \( \perp \)-preservation of \( f \).

**Lemma 53.** Let \( u, v \in B_1 \) be such that \( u \perp v \). Then for every \( u', v' \in B_1 \cup B_2 \), we have \( f(u, u') \perp f(v, v') \).

Proof. For a contradiction, we assume that \( \neg(f(u, u') \perp f(v, v')) \). Without loss of generality, we assume that \( f(u, u') \leq f(v, v') \). Let \( s, t \in B_1 \) be such that \( s < u \land v < t \land s \perp t \). Let \( s', t' \in B_1 \cup B_2 \) be such that \( s' \perp t' \). \( s', u' \perp t', v' \) are in the same orbit. By the domination of \( f \), we have \( f(s, s') < f(u, u') \land f(v, v') < f(t, t') \). Since \( f(u, u') > f(v, v') \), we have \( f(s, s') < f(t, t') \), a contradiction to \( \perp \)-preservation of \( f \).

**Lemma 54.** Let \( u, v \in B_1 \) and \( u', v' \in B_1 \cup B_2 \) be such that \( u < v \). Then \( f(u, u') < f(v, v') \lor f(u, u') \perp f(v, v') \).

Proof. For a contradiction, we assume that \( f(v, v') \leq f(u, u') \). Let \( s, t \in B_1 \) be such that \( t < v \land u < s \land s \perp t \). Let \( s', t' \in B_1 \cup B_2 \) be such that \( s' \perp t' \). \( s', u' \perp t', v' \) are in the same orbit. By the domination of \( f \), we have \( f(t, t') < f(v, v') \land f(u, u') < f(s, s') \). Since \( f(v, v') < f(u, u') \), we have \( f(t, t') < f(s, s') \), a contradiction to \( \perp \)-preservation of \( f \).

**Proof of Lemma 48** We are going to show that \( \text{Pol}(\Gamma) \) contains a function that behaves like \( e_\prec \) or \( e_\ll \) by checking the conditions of Lemma 42.

So let \( a, b \in P \) with \( a_p < a_q \) and \( \neg(b_p \leq b_q) \). We set \( Y := \{b_i : b_i \geq b_p\}, Z := \{b_i : \neg(b_i \geq b_p)\} \). By definition we have \( b_q \in Z \). By the homogeneity of \( \mathbb{P} \), there is \( \alpha \in \text{Aut}(\mathbb{P}) \) such that \( \alpha(Y) \subseteq B_2 \) and \( \alpha(Z) \subseteq B_1 \). Let \( \beta \in \text{Aut}(\mathbb{P}) \) such that \( \beta(\{a_i : i \in [k]\}) \subseteq B_1 \). Let \( g(x, y) := f(\beta(x), \alpha(y)) \). Clearly, \( g \in \text{Pol}(\Gamma) \).

By Lemma 52 we have that \( g(a_p, b_p) \perp g(a_q, b_q) \). Further we know by Lemma 53 that \( g(a_i, b_i) < g(a_j, b_j) \) or \( g(a_i, b_i) \perp g(a_j, b_j) \) holds for all \( a_i < a_j \). By Lemma 54 we know that \( g(a_i, b_i) \perp g(a_j, b_j) \) holds for all \( a_i < a_j \). So the conditions of Lemma 42 are satisfied. Hence \( e_\prec \) or \( e_\ll \) is a polymorphism of \( \Gamma \).

7.2 \( f(a, a) \perp f(b, c) \land f(a, a) \perp f(c, b) \)

The aim of this section is to prove the following.

**Lemma 55.** Let \( f \in \text{Pol}(\Gamma) \) be canonical as a function from \((P; <, \prec, a, b, c)\) to \((P; <)\). If \( f(a, a) \perp f(b, c) \land f(a, a) \perp f(c, b) \), then \( \text{Pol}^2(\Gamma) \) contains \( e_\prec \) or \( e_\ll \).

We define the following sets.

\[
B_1 := \{x \in P : a < x < b \land x \perp c\}
\]
\[
B_2 := \{x \in P : x < b \land x < c \land x \perp a \land x < a\}.
\]
Throughout the lemmata and corollaries below in this section, we assume that every binary canonical function in $\Gamma$ is dominated and $f(a, a) \perp f(b, c) \land f(a, a) \perp f(c, b)$.

Observe that by the homogeneity of $(P; \leq, \prec)$ and the back-and-forth argument, we can show that $(B_1 \cup B_2; \leq, \prec)$ is isomorphic to $(P; \leq, \prec)$, with $B_2$ being a random filter. For every two $k$-tuples $\bar{x}$ and $\bar{y}$ in $B_i^k$, $\bar{x}$ and $\bar{y}$ are in the same orbit of $\text{Aut}(\bar{P})$ if and only if $\bar{x}$ and $\bar{y}$ are in the same orbit of $\text{Aut}(P; a, b, c)$.

**Lemma 56.** $f$ has the same domination on sets $B_i \times B_j, i, j \in [2]$.

**Proof.** This lemma can be shown as in Lemma 50 and Lemma 51.

In the rest of this section we assume that $f$ is dominated by the first argument on $B_i \times B_j$ for every $i, j \in \{1, 2\}$. Similarly, to Lemma 52 we have the following.

**Lemma 57.** Let $u, v \in B_1$ and $u', v' \in B_2$ be such that $u < v \lor u \perp v$. Then $f(u, u') \perp f(v, v')$.

**Proof.** First we prove that $f(v, v') < f(u, u') \lor f(v, v') \perp f(u, u')$. For a contradiction we assume that $f(u, u') \leq f(v, v')$. Since $a < u \land a < u'$, we have $f(a, a) < f(u, u')$. Since $v < b \land v' < c$, we have $f(v, v') < f(b, c)$. Thus $f(a, a) < f(b, c)$, a contradiction to the fact that $f(a, a) \perp f(b, c)$. Thus $f(v, v') < f(u, u') \lor f(v, v') \perp f(u, u')$.

The proof is completed by showing that $f(u, u') \lor f(v, v')$ is impossible. For a contradiction, we assume that $f(u, u') > f(v, v')$. Let $s, t \in B_1$ be such that $s \perp t \land s < v \land u < t$. Let $s' \in B_2, t' \in B_1$ be such that $s' \perp t'$. By the domination of $f$, we have $f(s, s') < f(v, v') \lor f(u, u') < f(t, t')$. It follows from $f(u, u') > f(v, v')$, we have $f(s, s') < f(t, t')$, a contradiction to $\perp$-preservation of $f$.

**Lemma 58.** Let $u, v \in B_1$ be such that $u \perp v$. Then for every $u', v' \in B_1 \cup B_2$, we have $f(u, u') \perp f(v, v')$.

**Proof.** analogous to Lemma 53.

**Lemma 59.** Let $u, v \in B_1$ and $u', v' \in B_1 \cup B_2$ be such that $u < v$. Then $f(u, u') \perp f(v, v') \lor f(u, u') \perp f(v, v')$.

**Proof.** analogous to Lemma 54.

**Proof of Lemma 55** We are again going to show that $\text{Pol}(\Gamma)$ contains a function that behaves like $e_<$ or like $e_\leq$ by checking the conditions of Lemma 12.

So let $a, b \in I_1^k$ with $a_p < a_q$ and $\neg(b_p \leq b_q)$. We set $Y := \{b_i : b_i \geq b_p\}, Z := \{b_i : \neg(b_i \geq b_q)\}$. By definition we have $b_q \in Z$. By the homogeneity of $\bar{P}$, there is $\alpha \in \text{Aut}(\bar{P})$ such that $\alpha(Y) \subseteq B_1$ and $\alpha(Z) \subseteq B_2$. Let $\beta \in \text{Aut}(\bar{P})$ such that $\beta([a_i : i \in [k]]) \subseteq B_1$. Let $g(x, y) := f(\beta(x), \alpha(y))$. Clearly, $g \in \text{Pol}(\Gamma)$.

By Lemma 52 we have that $g(a_p, b_p) \perp g(a_q, b_q)$. Further we know by Lemma 54 that $g(a_i, b_i) < g(a_j, b_j)$ or $g(a_i, b_i) \perp g(a_j, b_j)$ holds for all $a_i < a_j$. By Lemma 53 we know that $g(a_i, b_j) \perp g(a_j, b_j)$ holds for all $a_i \perp a_j$. So the conditions of Lemma 42 are satisfied. Hence $e_<$ or $e_\leq$ is a polymorphism of $\Gamma$.  

8 The NP-hardness of Betw, Sep and Cycl

By Corollary 22 we are now left with the cases where $\text{End}(\Gamma)$ is equal to one of the monoids $(\emptyset, \emptyset)$ or $(\downarrow, \emptyset)$.

We are going to deal with all these remaining cases in this section. Interestingly, we can treat them all similarly: By fixing finitely many constants $c_1, \ldots, c_n$ on $\Gamma$ we obtain definable subsets of $(\Gamma, c_1, \ldots, c_n)$ on which $<$ and $\text{Low}$ are pp-definable. This enables us to reduce every such case to the NP-completeness of $\text{Low}$.

Lemma 60. Let $u, v \in P$ with $u < v$. Then the relations $<$ and $\text{Low}$ are pp-definable in $(P, \text{Betw}, \perp, u, v)$.

Proof. It is easy to verify that there is a pp-definition of the order relation by the following equivalence:

$$x < y \iff \exists a, b \ (\text{Betw}(x, y, a) \land \text{Betw}(y, a, b) \land \text{Betw}(u, v, a) \land \text{Betw}(v, a, b)).$$

The two maps $e_\leq : P^2 \to P$ and $e_\geq : P^2 \to P$ do not preserve Betw, since for every triple $\bar{a} = (a_1, a_2, a_3)$ with $a_1 < a_2 < a_3$ and $\bar{b} = (b_1, b_2, b_3)$ with $b_1 > b_2 > b_3$, the image of $(\bar{a}, \bar{b})$ forms an antichain.

By Theorem 46 we have that $\text{Low}$ is pp-definable in $(P, \text{Betw}, \perp, u, v)$. ▲

Theorem 61. Let $\Gamma$ be a reduct of $\mathbb{P}$ such that $\text{End}(\Gamma) = (\uparrow)$. Then there are constants $u, v, w, t \in P$ such that $(\{0, 1\}, \text{1IN3})$ is pp-interpretable in $(\Gamma, u, v, w, t)$. Hence $\text{CSP}(\Gamma)$ is NP-complete.

Proof. Note that the betweenness relation Betw is an orbit of $\text{End}(\Gamma) = (\uparrow)$ on $P^3$. Now Theorem 10 implies that Betw is primitively positive definable in $\Gamma$. For the same reason $\perp$ is pp-definable in $\Gamma$. By Lemma 60 there is pp-definition of $\text{Low}$ in $(\Gamma, u, v)$. By Theorem 46 we can find a pp-interpretation of $(\{0, 1\}, \text{1IN3})$ in $(\Gamma, u, v, w, t)$, where $w, t$ are two additional constants. Hence $\text{CSP}(\Gamma)$ is NP-complete. ▲

For the case where $\text{End}(\Gamma) = (\downarrow)$, we first need the following lemma:

Lemma 62. Let $c, d$ be two constants in $P$ such that $c < d$. Then there is a pp-interpretation of $(P; \text{Low})$ in $(P; \text{Cycl}, c, d)$

Proof. Let $X := \{ x \in P : c < x < d\}$. By using back-and-forth argument one can show easily that $(P; <)$ and $(X; <_{|X})$ are isomorphic. We first show that $X$ (as a unary predicate) and $<_{|X}$ are pp-definable in $(P; \text{Cycl}, c, d)$. It is easy to verify that the set $X$ can be defined in $(P; \text{Cycl}, c, d)$ by $\phi(x) := \text{Cycl}(c, x, d)$ and that $x <_{|X} y \iff \phi(x) \land \phi(y) \land \text{Cycl}(c, x, y)$. Now a pp-interpretation of $(P; <, \text{Cycl})$ in $(P; \text{Cycl}, c, d)$ is simply given by the identity on $X$.

By Lemma 23 we have that $\perp$ is pp-definable in $(P; <, \text{Cycl})$. It is easy to verify that $e_\leq$ and $e_\geq$ do not preserve Cycl. Therefore, by Theorem 46 Low is pp-definable in $(P; <, \text{Cycl})$, which concludes the proof of the Lemma. ▲

Theorem 63. Let $\Gamma$ be a reduct of $\mathbb{P}$ such that $\text{End}(\Gamma) = (\downarrow)$. Then there are constants $a, b, c, d \in P$ such that $(\{0, 1\}, \text{1IN3})$ is pp-interpretable in $(\Gamma, a, b, c, d)$. Hence $\text{CSP}(\Gamma)$ is NP-complete.

Proof. The cyclic order relation Cycl is an orbit of $\text{End}(\Gamma) = (\downarrow)$ on $P^3$. So Theorem 10 implies that Cycl is primitively positive definable in $\Gamma$. By Lemma 62 there is pp-definition of Low in $(\Gamma, c, d)$ with $c < d$. By Theorem 46 we can find a pp-interpretation of $(\{0, 1\}, \text{1IN3})$ in $(\Gamma, a, b, c, d)$, where $a, b$ are two additional constants. Hence $\text{CSP}(\Gamma)$ is NP-complete. ▲
In the following, we prove the NP-hardness of CSP\((P; \text{Sep})\) by using the same proof idea as the proof of NP-hardness of CSP\((P; \text{Cycl})\) in Section 8.

Lemma 64. Let \(c, d, u\) be constants in \(P\) such that \(c < d < u\). Then \((P; \text{Low})\) has a pp-interpretation in \((P; \text{Sep}, c, d, u)\).

Proof. Let \(X := \{x \in P : d < x < u\}\). By using a back-and-forth argument, one can show easily that \((X; \leq)\) and \(P\) are isomorphic. Similarly as in the proof of Theorem 63, \(X\) and \(<_{|X}\) are pp definable in \((P; \text{Sep}, c, d, u)\) as follows.

The set \(X\) can be defined by the formula \(\phi(x) := \text{Sep}(c, d, x, u)\), and \(<_{|X}\) can be defined by \(x <_{|X} y \iff \phi(x) \land \phi(y) \land \text{Sep}(c, d, x, y)\). Also \(\text{Cycl}(x, y, z)_{|X}\) can be defined by the primitive positive formula \(\phi(x) \land \phi(y) \land \phi(z) \land \text{Sep}(c, x, y, z)\).

So a pp-interpretation of \((P; <, \text{Cycl})\) in \((P; \text{Sep}, c, d, u)\) is simply given by the identity, restricted to \(X\). By Lemma 62, \(\text{Low}\) is pp-definable in \((P; <, \text{Cycl})\), which concludes the proof of the Lemma.

Theorem 65. Let \(\Gamma\) be a reduct of \(P\) such that \(\text{End}(\Gamma) = \{\uparrow, \downarrow\}\). Then there are constants \(a, b, c, d, u \in P\) such that \((\{0, 1\}, \text{1IN3})\) is pp-interpretable in \((\Gamma, a, b, c, d, u)\). Hence CSP\((\Gamma)\) is NP-complete.

Proof. The relation \(\text{Sep}\) is an orbit of \(\text{End}(\Gamma) = \{\uparrow, \downarrow\}\) on \(P^3\). So Theorem 10 implies that \(\text{Sep}\) is primitively positive definable in \(\Gamma\). By Lemma 64, there is pp-definition of \(\text{Low}\) in \((\Gamma, c, d, u)\) with \(c < d < u\). By Theorem 44, we can find a pp-interpretation of \((\{0, 1\}, \text{1IN3})\) in \((\Gamma, a, b, c, d, u)\), where \(a, b\) are two additional constants. Hence CSP\((\Gamma)\) is NP-complete.

9 Main Results

In this section we complete the proof of the complexity dichotomy for the Poset-SAT(\(\Phi\)) problems that we announced in Theorem 5 and that we reformulated as CSPs on the reducts of the random poset \(P\). We have proven an even stronger dichotomy that remains interesting even if \(P=\text{NP}\). This dichotomy regards model-theoretic properties of the reducts of \(P\) and can be also stated in terms of universal-algebra by what we saw in Section 3.5. We will phrase it in Theorem 67.

9.1 An algebraic dichotomy

Let \(\Gamma\) be a reduct of \(P\) and \(\Delta\) be its model-complete core. Throughout this paper we have studied the question whether there is a pp-interpretation of the structure \((\{0, 1\}, \text{1IN3})\) in \(\Delta\), extended by finitely many constants or not.

By Theorem 18 and Theorem 19, we know that this fact can be elegantly described with the help of topological clones. We sum up our results and show that - for reducts of the random poset - we can also give an additional characterization by weak near unanimity polymorphisms (modulo endomorphism). First we are going to look in detail at the case, where \(<\) and \(\bot\) are pp-definable.

Lemma 66. Let \(\Gamma\) be a reduct of \(P\) in which \(<\) and \(\bot\) are pp-definable. Then the following are equivalent:

1. There is a binary \(f \in \text{Pol}(\Gamma)\) which is not dominated.
2. The relation \(\text{Low}\) is not pp-definable in \(\Gamma\).
3. \(e_\text{<}\) or \(e_\leq\) is a polymorphism of \(\Gamma\).
4. There is a binary \( f \in \text{Pol}(\Gamma) \) and endomorphisms \( e_1, e_2 \in \text{End}(\Gamma) \) such that 
\[ e_1(f(x,y)) = e_2(f(y,x)) \]
5. For all \( c_1, \ldots, c_n \in \Gamma \) there is no clone homomorphism from \( \text{Pol}(\Gamma, c_1, \ldots, c_n) \) onto \( 1 \).
6. For all \( c_1, \ldots, c_n \in \Gamma \) there is no continuous clone homomorphism from \( \text{Pol}(\Gamma, c_1, \ldots, c_n) \) onto \( 1 \).
7. There is no pp-interpretation of \( (\{0,1\}; 1\text{IN}3) \) in any expansion of \( \Gamma \) by finitely many constants.

**Proof.**

The equivalences of the points (5)-(7) hold for all \( \omega \)-categorical structures \( \Gamma \) and were discussed in Theorem 19.

(1) \( \leftrightarrow \) (2) This is the statement of Lemma 45.

(2) \( \rightarrow \) (3): This is the statement of Theorem 46.

(3) \( \rightarrow \) (4): Set \( f = e< \) respectively \( f = e_\leq \).

(4) \( \rightarrow \) (5): If there are \( e_1, e_2, f \in \text{Pol}(\Gamma) \) satisfying the equation 
\[ e_1(f(x,y)) = e_2(f(y,x)) \]
then there are also such polymorphisms fixing finitely many elements \( c_1, \ldots, c_n \). This is true for all \( \omega \)-categorical cores, see Lemma 82 of \cite{17}. It follows that there is no clone homomorphism from \( \text{Pol}(\Gamma, c_1, \ldots, c_n) \) onto \( 1 \).

(7) \( \rightarrow \) (2): This follows from the contraposition of Theorem 44.

With Lemma 66 we are now able to show the following Theorem.

**Theorem 67.** Let \( \Gamma \) be a reduct of \( \mathbb{P} \) and let \( \Delta \) be the model-complete core of \( \Gamma \). Then the following are equivalent:

1. There is a binary \( f \in \text{Pol}(\Delta) \) and endomorphisms \( e_1, e_2 \in \text{End}(\Delta) \) such that 
\[ e_1(f(x,y)) = e_2(f(y,x)) \]
or there is a ternary \( f \in \text{Pol}(\Delta) \) and endomorphisms \( e_1, e_2, e_3 \in \text{End}(\Delta) \) such that 
\[ e_1(f(x,x,y)) = e_2(f(x,y,x)) = e_3(f(y,x,x)). \]
2. There is a pseudo Siggers polymorphism, i.e. a function \( f \in \text{Pol}(\Delta) \) and endomorphism \( e_1, e_2 \in \text{End}(\Delta) \) such that 
\[ e_1(f(x,x,y,z,y,z)) = e_2(f(y,x,z,x,z,y)). \]
3. For all \( c_1, \ldots, c_n \in \Delta \) there is no clone homomorphism from \( \text{Pol}(\Delta) \) onto \( 1 \).
4. For all \( c_1, \ldots, c_n \in \Delta \) there is no continuous clone homomorphism from \( \text{Pol}(\Delta) \) onto \( 1 \).
5. There is no pp-interpretation of \( (\{0,1\}, 1\text{IN}3) \) in any expansion of \( \Delta \) by finitely many constants.

**Proof.** First of all we remark that the equivalence of the points (2)-(5) holds for all \( \omega \)-categorical core structures and was discussed in Theorem 19.

In Theorem 21 we saw that the model-complete core \( \Delta \) is either equal to \( \Gamma \) or a reduct of \( (\mathbb{Q},<) \) or \( (\omega,=) \).

Suppose the core \( \Delta \) is a reduct of \( (\mathbb{Q},<) \) or \( (\omega,=) \). We know from the analysis of temporal constraint satisfaction problems that then the statement is true: By Theorem 10.1.1. in \cite{3} there is no pp-interpretation of \( (\{0,1\}, 1\text{IN}3) \) in \( \Delta \), if and only if an equation 
\[ e_1(f(x,x,y)) = e_2(f(x,y,x)) = e_3(f(y,x,x)) \]
holds in \( \text{Pol}(\Delta) \).

So let \( \Gamma = \Delta \). By Theorem 60 the equivalence (1)\( \leftrightarrow \) (4) holds when \( < \) and \( \bot \) are pp-definable in \( \Gamma \). In the remaining cases \( \text{End}(\Gamma) \) is equal to \( (\mathbb{P}, \downarrow) \) or \( (\mathbb{Q}, \downarrow) \) and we have a pp-interpretation of \( (\{0,1\}, 1\text{IN}3) \) in an extension of \( \Gamma \) with finitely many constants. Theorems 14, 61, 63 and 65.
9.2 A complexity dichotomy

For the complexity of the CSPs of reducts of $\mathbb{P}$ that are model-complete we have proven the following dichotomy:

▶ **Theorem 68.** Let $\Gamma$ be a reduct of $\mathbb{P}$ in a finite relational language and a model-complete core. Under the assumption $P \neq NP$ either

- one of the relations Low, Betw, Cycl, Sep is pp-definable in $\Gamma$ and CSP($\Gamma$) is NP-complete or
- CSP($\Gamma$) is tractable.

**Proof.** If Low, Betw, Cycl or Sep is pp-definable in $\Gamma$, the CSP($\Gamma$) is NP-complete by the Theorems 61, 65, 63 and 44.

By Theorem 21 the only remaining case is the one, where $<$ and $\perp$ are pp-definable, but Low is not. In this case $e_<$ or $e_{\leq}$ is a polymorphism of $\Gamma$ by Theorem 46. Theorem 34 then implies that the problem is tractable. ◀

▶ **Corollary 69.** Let $\Gamma$ be a reduct of $\mathbb{P}$ in a finite relational language. Under the assumption $P \neq NP$ the problem CSP($\Gamma$) is either NP-complete or solvable in polynomial time. Further the “meta-problem” of deciding whether a given problem CSP($\Gamma$) is tractable or NP-complete, is decidable.

**Proof.** By Theorem 21 we know that either $\Gamma$ is a model-complete core or $g_<$ or $g_\perp$ are endomorphisms of $\Gamma$. In the first case the dichotomy holds by Theorem 68, in the second case $\Gamma$ is homomorphically equivalent to a reduct of $(\mathbb{Q},<)$ and the dichotomy holds by the result in [6] respectively [5].

The main result in [12] imply that it is decidable if the relations $<$, $\perp$, Low, Betw, Cycl or Sep are pp-definable in $\Gamma$. By Lemma 24 the question whether $\Gamma$ is model-complete core or not is then also decidable. By Theorem 68 and Corollary 52 of [6] we have that the meta-problem is decidable. ◀

We finish with an algebraic version of our dichotomy that is a direct implication of Theorem 68.

▶ **Corollary 70.** Let $\Gamma$ be a reduct of $\mathbb{P}$ in a finite relational language and let $\Delta$ be its model complete core. Under the assumption $P \neq NP$ either

- CSP($\Gamma$) is NP-complete and all finite structures are pp-interpretible in $\Delta$, extended by finitely many constant, or
- CSP($\Gamma$) is tractable and the conditions (1)-(6) in Theorem 67 hold. □
