Abstract

Background: Ischemia/reperfusion (IR) injury of the intestine is a major problem in abdominal pathological condition and is associated with a high morbidity and mortality. The purpose of the study is to determine whether the L-carnitine can prevent the harmful effects of small intestinal IR injury in rats.

Methods: Thirty Sprague-Dawley rats were randomly divided into three groups. Sham operated group (S), for sham–operated, the IR group for rats submitted to 45-minute of intestinal ischemia and 2-hour reperfusion, and IR+L group for those IR group treated with L-carnitine before reperfusion. All the rats were given EmGFP labelled E. coli DH5\textalpha through gavage 2-hour before the operative procedure. Afterwards the bacterial translocation (BT) from mesenteric lymph nodes (MLN), liver, spleen, lung and portal vein blood were detected. And the colony forming units/g (CFU/g) were counted. The TNF-\textalpha, IL-1\beta, IL-6, and IL-10 in serum were measured by ELISA. The morphometric study was measured by Chiu’s classification.

Results: The levels of BT were higher in the IR group than IR+L group (P < 0.05). The E. coli DH5\textalpha was hardly detected in the S group. The IR+L rats had enhancement of IL-10 and suppressed production of serum TNF-\textalpha, IL-1\beta and IL-6, compared to IR group rats (P < 0.05). The degree of pathological impairment in small intestine was lighter in IR+L than IR group (P < 0.05).

Conclusions: The L-carnitine pretreatment has a positive effect on reducing levels of BT, on inhibiting secretion of proinflammatory cytokines, and on lessening intestinal mucosa injury during small intestinal IR injury.

Keywords: L-carnitine; Ischemia/reperfusion injury; Intestine

Introduction

The gastrointestinal tract is a tissue which is highly sensitive to ischemia-reperfusion (IR) injury in the body [1]. The intestinal IR injury is caused by many clinical conditions, including acute mesenteric ischemia, intestinal obstruction, incarcerated hernia, small intestine transplantation, neonatal necrotizing enterocolitis, trauma, and shock [2-4]. It is extremely dangerous and emergent for patients to have intestinal IR injury because it may result in an array of severe clinical syndromes, and even death [5]. Under the normal physiological situation, the maintenance of bacteria and their products in the intestine depends on mucosal mucin and a layer of epithelial cells, and the unbroken intestinal barrier is essential for health and survival. In addition, the epithelial cells have high metabolism activity, and it is also susceptible to oxygen deprivation with subsequent ischemia damage to enterocytes and their supporting structures [6]. The impairment of the intestinal barrier may lead to decrease in absorption of nutrition, and the bacteria in the intestine may translocate to blood and other organs due to the damage of the intestinal barrier. The consequences of the bacterial translocation (BT) and release of harmful substances produced by the bacteria into blood circulation are to activate inflammatory mediators and initiate Systemic Inflammatory Response Syndrome (SIRS) or Multiorgan Dysfunction Syndrome (MODS) [7, 8]. Thus, there is a great interest in exploring methods to protect the small intestine from lesions. L-carnitine is an important active material, which plays a crucial role in energy metabolism. The shortage of L-carnitine includes metabolism disruption and induction of a series of disorders. Xie et al’s study has demonstrated that L-carnitine has a protective effect on IR injury, which is partly due to its prevention of energy loss and its antioxidant activity [9]. Moreover, it has a protective effect on oxidative stress-induced DNA damage [10]. Oyanagi et al’s study [11] has demonstrated that L-carnitine can maintain mitochondrial function and sup-
press oleic acid-mediated membrane permeability transition (MPT) of mitochondria through acceleration of beta-oxidation. The opening of MPT has been proved as a key event in cell apoptosis or necrosis after IR injury [12, 13]. It has been suggested that L-carnitine would prevent apoptosis and maintain functions of cell. The purpose of this experiment is to explore the effects of L-carnitine on the rats suffering from the small intestinal IR injury through detecting translocation of EmGFP labelled E. coli from the mesenteric lymph nodes, liver, spleen and portal vein blood. Additionally, the small intestinal morphometric study was performed and the levels of serum cytokines (TNF-α, IL-1β, IL-6 and IL-10) were investigated.

Materials and Methods

Animals

A total of thirty adult SD rats were obtained from the Experimental Research Center of Zhengzhou University, and their weight is in the range of 280 - 320 g. All of the rats were maintained under standard conditions with controlled temperature (18 ± 4 °C), 12 hours light and 12 hours darkness cycle, and feeding with standard food and water. The maintenance of the experimental rats was administrated by licensed operators and these rats were given humane treatment. This study was approved by the Ethical Committee of Kunming Medical University.

Labeling of Escherichia coli

The Escherichia coli DH5α (donated from PHD Cao, the Department of Micro-organism of Kunming Medical University) was selected to label with EmGFP. The brief procedures are as follows. 1. Establishment of competent bacteria using CaCl₂ method. 2. Transformation of plasmid DNA (pRSET-EmGFP bought from the Invitrogen Company) into E. coli using the heat shock method. A mixture of the competent bacteria and the plasmid DNA were placed in iced bath for 30 minutes and put at 42 °C for 2 minutes (heat shock), and then placed back into the iced bath. After transformation, the bacteria were cultured on Luria-Bertani plate with ampicillin (100 mg/L) at 37 °C for 12 hours. Four colonies were inoculated into liquid media (200 ml) and grown at 37 °C with agitation for 16 hours in order to ensure growth of isolated colonies. The E. coli DH5α with transformed plasmid containing EmGFP were detected by using fluorescence microscopy.

Table 1. The Chiu’s Score Classification of Small Intestinal Injury

| Classification | Pathological change |
|----------------|---------------------|
| Level 0        | Mucosa without changes. |
| Level 1        | Well-constituted villosities, no cellular lysis or inflammatory process, although there is formation of Grunhagen’s sub-epithelial space. |
| Level 2        | Presence of cellular lysis, formation of Grunhagen’s sub-epithelial space and increased spacing among the villosities. |
| Level 3        | Destruction of the free villosities section, presence of dilated capillaries and inflamed cells. |
| Level 4        | Structural destruction of the villosities, only traces of some villosities, formed by inflamed cells and necrotic material, with hemorrhage and basal glandular ulceration. |
| Level 5        | Destruction of all the mucosa, no glandular structure can be seen, only the amorphous material laying on the sub-mucosa tissue. |
croscopic (Fig. 1). The bacteria were cultured for the study to the density of $7.5 \times 10^6$/ml.

**Intestinal IR injury model and operative procedures**

The thirty healthy SD rats were randomly divided into three groups (n = 10 for each group): sham operated group (S), IR group (IR) and IR+L-carnitine group (IR+L). All of the animals were given the EmGFP labeled E. coli 2 ml by gavage two hours before surgical procedures. The rats were anesthetized through injecting Urethane 200 mg/kg into the peritoneal cavity. In the S group, the rats received a 3-centimeter medium-length-wise laparotomy, and the small intestine was exposed. Subsequently, the superior mesenteric artery (SMA) was identified and dissected, and then the peritoneal cavity was closed. In the IR group, the rats underwent intestinal ischemia for 45 minutes through occlusion of the SMA and then the peritoneal cavity was closed. In the IR group, the rats underwent intestinal ischemia for 45 minutes through occlusion of the SMA and then the peritoneal cavity was closed. In the IR+L group, the rats were given intervention of intestinal ischemia, which was the same as that in the IR group, and they were injected L-carnitine 80 mg/kg suspended in saline solution (total volume = 2 ml) through tail vein before reperfusion injury. Meanwhile, the rats were given 2 ml saline solution instead of L-carnitine in both the S and IR groups.

At the end of the procedures, one milliliter venous system serum was collected in order to measure the levels of TNF-α, IL-1β, IL-6 and IL-10 in venous blood using ELISA. The rats were sacrificed and a one-centimeter segment of ileum was dissected and processed using standard histological techniques including formalin fixation, dehydration and paraffin embedding, and was subsequently cut into 4 μm sections and stained with Haematoxylin and Eosin. All of the sections were analyzed with an optic microscope by the pathologist who did not know which group each rat belonged to, and they were classified according to the degree of tissue injury in accordance to Chiu’s score classification [14] (Table 1). The homogenate of the mesenteric lymph nodes, liver, spleen, lung and half milliliter blood of portal vein were detected for the BT. Among the homogenate, 0.1 gram was cultured in agar culture media with ampicillin (100 mg/L) at 37 °C for 24 hours in order to count the CFU/g of bacteria.

**Statistical analysis**

Data was presented as mean ± standard derivation (SD). One-way analysis of variance (ANOVA) and Tukey Post Hoc (parametric) test were used to compare serum cytokines and translocation of bacteria between the three groups. Histopathologic grades of each group were compared using

| Groups | n | MLN    | Liver  | Lung   | Spleen  | Portal vein blood |
|--------|---|--------|--------|--------|---------|-------------------|
| S      | 10 | 1.2 ± 1.03* | 0.0 ± 0.00* | 0.0 ± 0.00* | 0.0 ± 0.00* | 2.0 ± 2.58* |
| IR     | 10 | 25.1 ± 3.41* | 20.5 ± 3.03* | 25.5 ± 3.92* | 15.2 ± 3.01* | 19.9 ± 3.70* |
| IR+L   | 10 | 11.3 ± 2.36 | 10.0 ± 2.58 | 10.8 ± 2.25 | 10.3 ± 3.43 | 9.3 ± 1.64 |

Δ P < 0.05 compared to IR and IR+L groups
* P < 0.05 compared to IR+L group

**Figure 2.** Normal intestinal mucosa in the S group rats (Grade 0) (H&E, × 100).

**Figure 3.** Intestinal villus after IR in group II rats, with lifted epithelium, white blood cells, and monocytes in the Lamina propria (Grade 4) (H&E, × 100).
Kruskal-Wallis test and Tukey Post Hoc (nonparametric) test. The significance level was established in $P < 0.05$ for all the tests.

Results

The levels of BT in different groups

The levels of BT had a significant increase in animals distributed to the IR group, compared to animals in the IR+L-carnitine and S groups ($P < 0.05$). In the S group, there were few colony forming units in culture plates of MLN and portal vein blood (Table 2).

Changes of intestinal mucosa under light microscope

The villus and glands were normal and inflammatory cell infiltration was not observed in mucosal epithelial layer in the sham operated group (Fig. 2). Multiple erosions, inflammatory cells and bleeding were observed in the IR group (Fig. 3). Lighter edema of mucosa villus and fewer infiltration of necrotic epithelial inflammatory cells neutrophil leukomonocyte were found in mucosa epithelial layer in IR+L group than the IR group (Fig. 4).

Table 3. The Levels of Chiu’s Score in Small Intestinal Structure ($\text{Mean} \pm \text{SD}$)

| Groups    | n | Small intestinal structure |
|-----------|---|----------------------------|
| S         | 10| $0 \pm 0.00^*$             |
| IR        | 10| $4.0 \pm 0.41^*$           |
| IR+L      | 10| $2.4 \pm 0.46$             |

$^\Delta P < 0.05$ compared to IR and IR+L groups
$^* P < 0.05$ compared to IR+L group

Chiu’s score of small intestinal structure

In all of the three groups, the Chiu’s score was highest in the IR group, and it was lowest in the S group ($P < 0.05$). The score in the IR+L group was significantly lower than that in the IR group ($P < 0.05$) (Table 3).

Changes in TNF-α and interleukins in vena systemic serum

The concentrations of pro-inflammatory factors including TNF-α, IL-1, and IL-6 in the experimental rats’ serum in the IR and IR+L group were higher than that in the S group ($P < 0.05$). And the levels of TNF-α, IL-1 and IL-6 in the IR group rats were higher than that in the IR+L group ($P < 0.05$). The levels of inhibitive inflammatory factor IL-10 in the IR+L group were lower than that in the IR group ($P < 0.05$) (Table 4).

Discussion

The primary functions of the intestine are to absorb nutrients and exclude food debris, bacteria and their products. The maintenance of these functions relies on the integrity of mucosal and barrier of intestine. However, under certain pathological circumstances such as intestinal IR injury, the intestine may lose its barrier function so that the systemic microbial infection, and even MODS could be induced [7]. Compared to other internal organs, the intestine is the organ that is most sensitive to IR injury in the body [15, 16]. There is increasing evidence from experimental and clinical studies to support the ‘intestinal hypothesis of sepsis’, which is based on bacterial or endotoxin translocation from the intestinal lumen to the extra-intestinal sites [17]. Nevertheless, growing acceptance of the ‘intestinal hypothesis of sepsis’ was mainly triggered by indirect supports rather than concrete scientific evidence.

IR injury of the intestine is a complex, multifactorial, and pathophysiological process that involves the dysfunction of absorption, BT, actions of oxygen-derived free radicals, cytokines, nitric oxide, and PMNs [18]. IR injury to the small intestine causes local production of the ROS, which is known to play an important role in gut epithelial damage [19]. Intestinal mucosal mast cells (IMMC) are particularly frequent in close proximity to epithelial surfaces, where they are strategically located for optimal interaction with the environment and for their putative functions of host defense [20]. Previous studies have demonstrated that the degranulation of IMMC can be induced by oxidants generated in the post-ischemic gut, and the released inflammatory mediators such as histamine and tumor necrosis factor-α (TNF-α) could aggravate the injury to intestine after reperfusion [21, 22]. In line with general IR-induced cell damage, also in intestinal
IR, apoptosis is the major mode of cell death in the destruction of epithelial cells [23].

The intestinal IR injury can lead to mucosal cells energy exhaustion and is also associated with decrease in ATP synthesis [24-26]. Mitochondrium is one of the most important organelle and regarded as a “dynamic factory”, and it is vulnerable to injury due to IR. Undoubtedly, the damage of mitochondria will induce energy exhaustion and failure of maintenance of cellular basic functions. The defective mitochondrial oxidative phosphorylation and metabolic compromise play an important role in IR injury [27]. Increased ROS changes the mitochondrial membrane permeability and results in opening of mitochondrial permeability transition (MPT) [28]. The opening of MPT is a key event in cell death after ischemia-reperfusion [12, 13, 29]. Opening of the non-specific mitochondrial permeability transition pore (mPTP) in the inner mitochondrial membrane results in the collapse of the membrane potential (Δψm), uncoupling of the respiratory chain, and efflux of cytochrome c and other proapoptotic factors that may lead to either apoptosis or necrosis [30]. Opening of the mPTP is triggered by Ca2+ overload and excessive production of ROS in the early minutes of reflow, which is crucial event in reperfusion injury [31, 32]. Griffiths and Halestrap’s study [33] have demonstrated that in isolated rat heart, the mPTP remained closure throughout ischemia but opened at the time of reperfusion.

L-Carnitine can carry long-chain fatty acylgroups into mitochondria for beta-oxidation. And it acts as a scavenger of oxygen free radical, relief of oxidative stress, and reduction of lipid peroxidation [34]. Therefore, L-Carnitine plays a protective role in metabolic disorders. Virmani and Gaetani’s study [35] revealed that L-carnitine could maintain the MPT and modulate the activation of the mitochondrial permeability transition pores (mPTP), especially the cyclosporin-dependent mPTP. Furthermore, their preliminary experiments also showed that LC may reduce the peroxynitrite levels and protect against the underlying mechanism of methamphetamine toxicity [36].

In conclusion, the increase of L-carnitine density in IR intestine is a protective event. Mucosal injury and BT were reduced in the L-carnitine group, compared with the IR group (P less than 0.05). And L-carnitine effectively inhibited releasing of pro-inflammatory factors, compared with IR group (P less than 0.05). In addition, L-carnitine can protect intestine from IR injury because it can improve absorption of nutrients and prevention of BT. Nevertheless, clinical investigations will be required in order to confirm the effectiveness of L-carnitine as a therapeutic agent in clinical practice.
