Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company’s public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
Implications of social media misinformation on COVID-19 vaccine confidence among pregnant women in Africa

Abstract

It has been over a year since the World Health Organization (WHO) declared the outbreak of COVID-19 as a Public Health Emergency of International Concern and subsequently a global pandemic. The world has experienced a lot of uncertainty since then as we all get used to this new ‘normal’ with social distancing measures, lockdowns, the emergence of new variants, and an array of hope with the development of vaccines. Having an abstract understanding of vaccine delivery, public perceptions of vaccines, and promoting acceptance of vaccines are critical to tackling the pandemic. The advent of the pandemic has led to the emergence of an ‘infodemic’ or rampant misinformation surrounding the virus, treatment, and vaccines. This poses a critical threat to global health as it has the potential to lead to a public health crisis by exacerbating disease spread and overwhelming healthcare systems. This ‘infodemic’ has led to rising vaccine hesitancy which is of paramount concern with the WHO even identifying it as one of the ten main threats to global health almost 2 years before the approval of COVID-19 vaccines. Pregnant African women are one of the most vulnerable population groups in a region with already burdened healthcare systems. Currently, there isn’t ample research in the literature that explores vaccine hesitancy in this subpopulation and the impact of social media misinformation surrounding it. The aim of this paper is to highlight the implications of this ‘infodemic’ on the pregnant African population and suggest key recommendations for improved healthcare strategies.

1. Introduction

It has been over a year since the World Health Organization (WHO) declared the outbreak of COVID-19 as a Public Health Emergency of International Concern and subsequently a global pandemic. The world has experienced a lot of uncertainty since then as we all get used to this new ‘normal’ with social distancing measures, lockdowns, the emergence of new variants, and an array of hope with the development of vaccines. Having an abstract understanding of vaccine delivery, public perceptions of vaccines, and promoting acceptance of vaccines are critical to tackling the pandemic and protecting vulnerable populations worldwide. As of October 13, 2021, there were more than 6 million confirmed cases and 148,000 reported deaths in Africa which is likely to be a profound underestimate of the actual figures due to the low testing capacity in the region.

The advent of the pandemic has led to the emergence of an ‘infodemic’ or rampant misinformation surrounding the virus, treatment, and vaccines. This poses a critical threat to global health as it has the potential to lead to a public health crisis by exacerbating disease spread and overwhelming healthcare systems. This ‘infodemic’ has led to rising vaccine hesitancy which is of paramount concern with the WHO even identifying it as one of the ten main threats to Global health almost 2 years before the approval of COVID-19 vaccines. Africa remains to have some of the lowest vaccination rates globally with an overall figure of only 4.4% fully vaccinated compared to 66% in the UK.

Pregnant African women are one of the most vulnerable population...
groups in a region with an already burdened healthcare system. Currently, there isn’t ample research in the literature that explores vaccine hesitancy in pregnant African women and the impact of social media misinformation surrounding it.\textsuperscript{16,17} The aim of this paper is to highlight the implications of this ‘infodemic’ on the pregnant African population and suggest key recommendations for improved healthcare strategies.

2. Current misinformation on social media

In recent years, various social media platforms are found to be riddled with unfactual statements and conspiracy theories, this abrupt wave of false medical narratives can make them an unreliable source of information for the public. Some of the false claims that have been circulated widely on social media include ingestion of sea lettuce or injecting disinfectant for protection against COVID-19.\textsuperscript{18-20} Numerous websites have claimed that Bill Gates is planning to monitor individuals and keep a digital record of their COVID-19 vaccines and testing through injected microchips, this particular claim has been shared over 3000 times on Twitter and at least 1000 times on Facebook.\textsuperscript{18} In addition, a study conducted by Jad Melki et al. showed that a large number of study subjects believe misinformation from social media platforms to be true.\textsuperscript{15}

National efforts to tackle vaccine misinformation on social media in the African region.

Misinformation regarding coronavirus disease 2019 (COVID-19) poses a significant threat to public health as it has the potential to exacerbate public health issues by encouraging disease spread. Effective communication is essential to ensure that people understand how to protect themselves and others from the virus. The World Health Organization (WHO) and its partners have been working tirelessly to filter through the noise on social media in order to give reliable COVID-19 guidance. Rumors can swiftly spread online and can lead to the disruption of vaccine campaigns. In Kenya, for example, false statements regarding COVID-19 vaccines disrupting the menstrual cycle began to circulate online in May 2021.

The Africa Infodemic Response Alliance (AIRA), a WHO and partner organization program started in December 2020, used social media “listening tools” to spot misinformation and track it as it went viral.\textsuperscript{18} In response to this rapidly spreading rumor, they promptly created a video featuring a well-known vaccine introduction specialist to dispel the menstrual cycle misconceptions and provide accurate information. In a matter of days, millions of people had viewed it, and is currently in the process of being translated into Kenya’s native language, Kiswahili, so the Kenyan government can use it as well.\textsuperscript{17}

AIRA’s tools monitor social media for misleading COVID-19 claims and counter them with scientifically correct information. The technologies can identify potentially harmful rumors by counting how many people are sharing them, how quickly they spread, and how much emotion they elicit. Their primary challenge is making sure that the scientifically accurate video created becomes viral and reaches the audiences who are being misled. One of their objectives is to swiftly identify information gaps before erroneous information spreads.\textsuperscript{18}

Additionally, a recent study has concluded that anti-vaccine social media users were far more effective in persuading people who were undecided about vaccines than pro-vaccine communities.\textsuperscript{14} In March, a social content hub (Viral Facts Africa) was initiated which generates and distributes therapeutic vaccines are essential in the fight against this pandemic. Social media has played a fundamental role in propagating false COVID-19 related vaccine narratives amongst pregnant women in Africa. This emerging wave of anti-vaccination campaigns has since created a series of apprehensive responses amongst this vulnerable unique subpopulation to vaccine confidence.\textsuperscript{22,23} As a result, this has generated profound anxiety, reluctance, fear, and hesitancy in actively seeking the COVID-19 vaccine during this critical period of time for these women.\textsuperscript{29}

By paying close attention to the recent literature, we can observe some serious complications of this disease for both pregnant women and the unborn child. For instance, the incidence of preterm births, Cesarean section rates, low birth weight, and prolonged neonatal intensive care admissions appear to be higher in pregnant women affected with COVID-19 than the general population.\textsuperscript{24}

Moreover, due to this ongoing health crisis, there is an increased burden on healthcare systems in Africa, adversely affecting the maternal and neonatal outcomes in a historically exhausted health system.\textsuperscript{30}

Furthermore, increasing pregnancy-related complications such as preeclampsia are seen to be significantly exacerbated by the COVID-19 infection and hence leading to rapid worsening of the course of illness perinatally and postpartum.\textsuperscript{31} These possible implications as well as lessons learned from previous infections in the past during pregnancy indicate the urgent need for interventions such as accelerated vaccine rollout and reinforced vaccine uptake awareness efforts.\textsuperscript{32}

4. Recommendations for change

Exploring the different reasons behind this prevailing hesitancy in vaccine uptake among the African pregnant population can aid in
understanding the contributory factors and thus help maximize vaccine uptake. By highlighting the crucial role of social media and the impact it carries in influencing the opinions of the public, we can utilize this powerful tool in raising awareness and promoting vaccine confidence.35,36

Various public health entities ought to work very closely alongside popular and relevant social media platforms such as WhatsApp, Facebook, Instagram, and Twitter in an integrated approach to combat vaccine misinformation.7 Conducting government surveillance programs on different social media platforms which would be protected by guidelines according to the national authorities will help in proper education and circulating evidence-based information rather than sharing myths and misconceptions surrounding the COVID-19 vaccination.

Additionally, governments should dedicate adequate time to understanding and further developing effective health communication programs broadcasted in the communities and tailored to social media users as well as initiating targeted online campaigns to promote scientific awareness surrounding the COVID-19 pandemic.43

Furthermore, an online smart system can be utilized to address false and inaccurate information on social media on the basis of chatbots to help answer pregnant women’s medical queries related to the COVID-19 vaccine effects and potential concerns. This innovative strategy has been employed in recent years and it has already shown promising outcomes in the virtual fight against COVID-19.41–43

We encourage and strongly recommend introducing free vaccination programs for this unique subcategory of the population as it has yielded favorable results in other countries.44 It is imperative to note the increasing psychological, emotional, and physical burden of this pandemic on pregnant women as well as the healthcare system, therefore, the introduction of such public health measures in alignment with regulated social media campaigns may tremendously result in an increased public awareness of the benefits of the vaccine during pregnancy in the African population.35

5. Conclusion

Misinformation related to COVID-19 has led to negative ramifications on vulnerable groups, particularly the pregnant women in the African region. This ‘infodemic’ adds to further challenges in promoting vaccine confidence among the pregnant population. By ensuring global collaborations, online awareness campaigns, research, and funding directed to understanding gender-focused vaccine hesitancy, the healthcare burden from COVID-19 can be ameliorated.
