Abstract
In this paper, we devise a systematic procedure to obtain nonlocal symmetries of a class of scalar nonlinear ordinary differential equations (ODEs) of arbitrary order related to linear ODEs through nonlocal relations. The procedure makes use of the Lie point symmetries of the linear ODEs and the nonlocal connection to deduce the nonlocal symmetries of the corresponding nonlinear ODEs. Using these nonlocal symmetries, we obtain reduction transformations and reduced equations to specific examples. We find that the reduced equations can be explicitly integrated to deduce the general solutions for these cases. We also extend this procedure to coupled higher order nonlinear ODEs with specific reference to second-order nonlinear ODEs.

1. Introduction
Over the last two decades or so, there has been increased interest in finding the nonlocal symmetries of ordinary differential equations (ODEs) [1–4]. Consider an nth-order ordinary differential equation

\[ A \equiv \frac{d^n x}{dt^n} + F(t, x, x^{(1)}, x^{(2)}, \ldots, x^{(n-1)}) = 0, \quad x^{(k)} = \frac{dx^k}{dt}, \quad (1) \]

to be invariant under the infinitesimal transformations

\[ X = x + \epsilon \eta(t, x), \quad T = t + \epsilon \xi(t, x), \]

where \( \xi \) and \( \eta \) are the infinitesimal point symmetries associated with the given equations. The vector field associated with the Lie point symmetry [5, 6] is then

\[ V = \xi(t, x) \frac{\partial}{\partial t} + \eta(t, x) \frac{\partial}{\partial x}. \]
The Lie point symmetries $\xi(t, x)$ and $\eta(t, x)$ are obtained by solving the invariant condition, that is,

$$V(n)(A)|_{A=0} = 0,$$

(2)

where

$$V(n) = \xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial x} + \eta^{(1)} \frac{\partial}{\partial x(t)} + \cdots + \eta^{(n)} \frac{\partial}{\partial x^{(n)}},$$

(3a)

$$\eta^{(k)} = \frac{d\eta^{(k-1)}}{dt} - x^{(k)} \frac{d\xi}{dt}, \quad \eta^{(0)} = \eta,$$

(3b)

is the $n$th prolongation. Thus, the point symmetries $\xi(t, x)$ and $\eta(t, x)$ can be calculated in an algorithmic way for a differential equation of any order. However, there exist more generalized symmetries such as contact symmetries, involving derivatives of $x$ in $\eta$ and $\xi$, and nonlocal symmetries, involving nonlocal terms in $\eta$ and $\xi$.

The vector field of the nonlocal symmetries is of the form

$$V = \xi(t, x, \int u(t, x) \, dt) \frac{\partial}{\partial t} + \eta(t, x, \int u(t, x) \, dt) \frac{\partial}{\partial x}.$$ 

Unlike the case of point symmetries, these nonlocal symmetries cannot be determined completely in an algorithmic way because of the presence of nonlocal terms. The role of such nonlocal symmetries in the integration of differential equations was illustrated by Abraham-Shrauner et al and later on by others [1–4]. Conventionally, such nonlocal symmetries are explored either by reducing or increasing the order of the equation [1, 3]. Methods to identify nonlocal symmetries of partial differential equations were also developed simultaneously [7, 8, 9]. In a recent paper, the nonlocal symmetries of two higher dimensional generalizations of the modified Emden equations were studied [10]. The first system is made up of two uncoupled modified Emden equations. The second system is obtained by assuming the variable of the scalar modified Emden equation to be complex and separating the real and imaginary parts [11].

In this paper, we devise a procedure to identify the nonlocal symmetries of a class of ODEs which includes the Riccati and Abel chains [12]. In this procedure, we nonlocally map the symmetries of the given $n$th-order nonlinear ODE to the point symmetries of the associated $n$th-order linear ODE, thereby preserving the order of the equation. We also show with the aid of specific examples (second-order, third-order and coupled second-order ODEs) that one can obtain the known general solution of a given equation using the associated nonlocal symmetries identified by this procedure. In developing this procedure, we make a judicious use of our earlier work on the nonlocal connection between nonlinear and linear ODEs [13] to construct the nonlocal symmetries for a given nonlinear ODE. We show that the same procedure is applicable to any order starting from 2 to arbitrary $N$. Further, we extend the procedure to deduce the nonlocal symmetries of a class of coupled second-order ODEs, which includes the coupled modified Emden equation [14].

The structure of the paper is as follows. In section 2, we describe the general procedure to obtain the nonlocal symmetries associated with a class of second-order nonlinear ODEs. Using the nonlocal symmetries, we deduce the general solution for two interesting equations belonging to this class of equations. Further, we extend the procedure to a more general class of second-order ODEs. In section 3, we extend the applicability of the procedure to a class of third-order ODEs. In section 4, we apply this procedure to a class of $n$th-order ODEs and deduce the associated nonlocal symmetries. In section 5, we extend the procedure to a class of coupled second-order ODEs and obtain their nonlocal symmetries. Further, we deduce the general solution of the coupled modified Emden-type equation using its nonlocal symmetries. In section 6, we summarize our results. In the appendix, we demonstrate briefly how the nonlocal symmetries identified through the developed procedure indeed satisfy the symmetry invariant condition (2).
2. Nonlocal symmetries

Let us consider the following class of nonlinear second-order ODE:

\[ \ddot{x} + \left( n - 1 \right) \dot{x}^2 + \left( c_1 + 2f \right) + \frac{1}{n} x f_x \ddot{x} + \frac{x}{n} \left( f^2 + c_1 f + c_2 \right) = 0, \quad f_x = \frac{\partial f}{\partial x}, \]  

(4)

where \( \left( = \frac{\text{d}}{\text{d}t} \right) \), which is related to the second-order linear ODE,

\[ \ddot{U} + c_1 \dot{U} + c_2 U = 0 \quad \left( \left( = \frac{\text{d}}{\text{d}t} \right) \right) \]  

(5)

through the nonlocal transformation

\[ U = x^p e^{\int f(x) \text{d}x}. \]  

(6)

Here \( c_1, c_2 \) and \( n \) are real constants and \( f = f(x) \) is an arbitrary given function. Equation (4) includes many physically and mathematically interesting equations such as the modified Emden equation [15, 16], Ermakov–Pinney equation [17] and a generalized Duffing–van der Pol equation. Equation (4) reduces to the Liénard class of equations for the parametric choice \( n = 1 \). Classification of the forms of \( f(x) \) for this Liénard class of equations admitting Lie point symmetries has been carried out in [18, 19]. We note that for arbitrary forms of \( f(x) \), equation (4) admits only the time translation symmetry. In addition to the Lie point symmetries admitted by equation (4), there exist other generalized symmetries such as contact symmetries, nonlocal symmetries and so on. In order to explore the nonlocal symmetries associated with (4), we use the identity

\[ \dot{U} = \frac{n\dot{x}}{x} + f(x), \]  

(7)

which can be directly deduced from (6).

2.1. General theory

The above nonlocal connection between equations (4) and (5) allows us to deduce the nonlocal symmetries of equation (4). To verify this, we proceed as follows. Let \( \xi \) and \( \eta \) be the infinitesimal point transformations, that is, \( U' = U + \epsilon \eta(t, U), \ T = t + \epsilon \xi(t, U) \), associated with the linear ODE (5). Then the symmetry vector field associated with the infinitesimal transformations reads as

\[ \Lambda = \xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial U}, \]  

(8)

and the first extension is

\[ \Lambda^1 = \xi \frac{\partial}{\partial t} + \eta \frac{\partial}{\partial U} + \left( \dot{\eta} - \dot{U} \dot{\xi} \right) \frac{\partial}{\partial \dot{U}}. \]  

(9)

Let us designate the symmetry vector field and its first prolongation of the nonlinear ODE (4) to be of the form

\[ \Omega = \lambda \frac{\partial}{\partial t} + \mu \frac{\partial}{\partial x} \]  

(10)

and

\[ \Omega^1 = \lambda \frac{\partial}{\partial t} + \mu \frac{\partial}{\partial x} + \left( \dot{\mu} - \dot{x} \dot{\lambda} \right) \frac{\partial}{\partial \dot{x}}, \]  

(11)

respectively, where \( \lambda \) and \( \mu \) are the infinitesimals associated with the variables \( t \) and \( x \), respectively.
Theorem 1. Given the set of Lie point symmetries $\xi$ and $\eta$ of the linear ODE (5), a set of nonlocal symmetries $\lambda$ and $\mu$ of the nonlinear ODE (4) follows therefrom.

Proof. From identity (7), we define
\[
\dot{U} = \frac{nx}{x} + f(x) = X.
\] (12)
The above relation is a contact-type transformation using which one can rewrite equations (4) and (5) as the Riccati equation
\[
\dot{X} + X^2 + \epsilon_1X + \epsilon_2 = 0 \quad \left(\frac{d}{dt}\right).
\] (13)
The symmetry vector field of this equation can be obtained by using the relation $X = \dot{U}$ and rewriting equation (9) as
\[
\lambda \frac{\partial}{\partial t} + \left[\frac{\eta}{U} \dot{U}^2 - X \dot{\xi}\right] \frac{\partial}{\partial X} = \Sigma. \tag{14}
\]
We note that equation (13), being a first-order ODE, admits infinite number of Lie point symmetries. These Lie point symmetries of equation (13) become contact symmetries of the linear second-order ODE (5) through the relation $X = \dot{U}$.

Similarly, one can rewrite equation (11) using the relation $X = n \dot{x} + f(x)$ as
\[
\Omega = \lambda \frac{\partial}{\partial t} + \left[\left(-\frac{n}{x^2} \dot{x} + f_x\right)\mu + (\dot{\mu} - \dot{x} \lambda)\frac{n}{x} \frac{\partial}{\partial X}\right] = \Xi, \quad f_x = \frac{\partial f}{\partial x}. \tag{15}
\]
As the symmetry vector fields $\Sigma$ and $\Xi$ are for the same equation (13), their infinitesimal symmetries must be equal. Therefore, comparing equations (14) and (15), one obtains
\[
\xi = \lambda, \quad \left[\frac{\eta}{U} - \frac{\eta \dot{U}}{U^2} - f(x) \dot{\xi}\right] = \left[\left(-\frac{n}{x^2} \dot{x} + f_x\right)\mu + \mu \frac{n}{x}\right]. \tag{16}
\]
Rewriting the second equation in (16), we arrive at the relation
\[
\frac{n}{x^2} \mu + \left(-\frac{n}{x^2} \dot{x} + f_x\right) \mu = \left[\frac{d}{dt} \left(\frac{\eta}{U}\right) - f(x) \dot{\xi}\right]. \tag{17}
\]
Since the infinitesimal symmetries $\xi$ and $\eta$ of the linear ODE are known and $U$ in (17) is taken in the form (6), the right-hand side now becomes an explicit function of $t$ and $x$. Solving the resultant first-order linear ODE, one can obtain the function $\mu$ which is nothing but the symmetry associated with the nonlinear ODE, see the appendix. Since $U$ is given by the nonlocal form (6), the resultant symmetries in general turn out to be nonlocal ones. \(\square\)

2.2. Examples

(a) Example 1. In order to illustrate the above theory, we consider the simple parametric choice $c_1 = c_2 = 0$ for which equations (4) and (5) reduce to the forms
\[
\ddot{x} + (n - 1) \frac{x^2}{x} + 2 \dot{x} f + \frac{1}{n} \dot{x} \ddot{x} f_x + \frac{x}{n} f^2 = 0, \quad f_x = \frac{\partial f}{\partial x}, \tag{18}
\]
and
\[
\dot{U} = 0, \tag{19}
\]
respectively. It is well known that the free particle equation (19) admits the following eight Lie point symmetries, see for example [5, 6, 22]:

\[
\begin{align*}
\Lambda_1 &= \frac{\partial}{\partial t}, && \Lambda_2 = \frac{\partial}{\partial U}, && \Lambda_3 = t \frac{\partial}{\partial U}, && \Lambda_4 = U \frac{\partial}{\partial U}, && \Lambda_5 = U^2 \frac{\partial}{\partial U}.
\end{align*}
\]

(20)

\[
\begin{align*}
\Lambda_6 &= t \frac{\partial}{\partial t}, && \Lambda_7 = t^2 \frac{\partial}{\partial t} + tU \frac{\partial}{\partial U}, && \Lambda_8 = U \frac{\partial}{\partial t} + U^2 \frac{\partial}{\partial U}.
\end{align*}
\]

Substituting the above symmetry generators \( \Lambda_8, i = 1, 2, \ldots, 8 \), and \( U = x e^{f(x)h} \), in equation (17), we obtain \( \xi = \lambda \) and the following seven first-order ODEs for \( \mu \),

\[
\begin{align*}
\frac{n}{x} \frac{\partial f}{\partial \mu} + \left( f_r - \frac{n}{x^2} \right) \mu + (xf + n\ddot{x})x^{-(n+1)} e^{-f(x)h} &= 0, \\
\frac{n}{x} \frac{\partial f}{\partial \mu} + \left( f_r - \frac{n}{x^2} \right) \mu - (xf + n\ddot{x})x^{-(n+1)} e^{-f(x)h} &= 0, \\
\frac{n}{x} \frac{\partial f}{\partial \mu} + \left( f_r - \frac{n}{x^2} \right) \mu = 0, \\
\frac{n}{x} \frac{\partial f}{\partial \mu} + \left( f_r - \frac{n}{x^2} \right) \mu + (xf + n\ddot{x})f x^{n-1} e^{-f(x)h} &= 0, \\
\frac{n}{x} \frac{\partial f}{\partial \mu} + \left( f_r - \frac{n}{x^2} \right) \mu + f(x) &= 0, \\
\frac{n}{x} \frac{\partial f}{\partial \mu} + \left( f_r - \frac{n}{x^2} \right) \mu + 2xf - 1 &= 0, \\
\frac{n}{x} \frac{\partial f}{\partial \mu} + \left( f_r - \frac{n}{x^2} \right) \mu + 2(xf + n\ddot{x})x^{2n-1} f e^{2f(x)h} - 1 &= 0.
\end{align*}
\]

Integrating each one of the above first-order linear ODEs, we obtain the corresponding infinitesimal symmetry \( \mu \). Substituting the infinitesimal symmetries \( \lambda \) and \( \mu \) into (10), we obtain the following nonlinear symmetries of equation (18):

\[
\begin{align*}
\Omega_1 &= \frac{\partial}{\partial t}, \\
\Omega_2 &= \left( \frac{x^{-n}}{n} e^{(\frac{1}{2} f_r - f)d\mu} - \frac{1}{n^2} \int x^{1-n} f_x e^{(\frac{1}{2} f_r - f)d\mu} \, dx \right) x e^{-\frac{1}{2} f(x)h} \frac{\partial}{\partial x}, \\
\Omega_3 &= \left( \frac{x^{-n}}{n} t e^{(\frac{1}{2} f_r - f)d\mu} - \frac{1}{n^2} \int t x^{1-n} f_x e^{(\frac{1}{2} f_r - f)d\mu} \, dx \right) x e^{-\frac{1}{2} f(x)h} \frac{\partial}{\partial x}, \\
\Omega_4 &= x e^{-\frac{1}{2} f(x)h} \frac{\partial}{\partial x}, \\
\Omega_5 &= x^n e^{(\frac{1}{2} f_r d\mu} - \left( \frac{1}{n} \int x^{n-1} f (nx + xf) e^{(\frac{1}{2} f_r + f)d\mu} \, dx \right) x e^{-\frac{1}{2} f(x)h} \frac{\partial}{\partial x}, \\
\Omega_6 &= t \frac{\partial}{\partial t} - x e^{-\frac{1}{2} f(x)h} \left( \frac{1}{n} \int f e^{(\frac{1}{2} f_r)d\mu} \, dx \right) \frac{\partial}{\partial x}, \\
\end{align*}
\]

(28)

(29)

(30)

(31)

(32)

(33)
\[ \Omega_7 = t^2 \frac{\partial}{\partial t} + x e^{-x f + d} \left( \frac{1}{n} \int (1 - 2f) e^{-\frac{x f}{n} + d} \, dt \right) \frac{\partial}{\partial x}. \]  
(34)

\[ \Omega_8 = t x^n e^{f d} \frac{\partial}{\partial t} + x e^{-x f + d} \left( \frac{1}{n} \int x^{n-1} (tx f^2 + n(t f - 1) \dot{x}) e^{(x f + d)} \, dt \right) \frac{\partial}{\partial x}. \]  
(35)

One can verify that each one of the above nonlocal symmetries indeed satisfies the invariance condition (2) and is the nonlocal symmetry vector field of (18). This is demonstrated in the appendix for a particular symmetry vector, namely \( \Omega_2 \), as an example.

We note here that there is also a possibility of finding the nonlocal symmetries of equation (18) by introducing suitable auxiliary/covering equation and deducing the point symmetries associated with the combined system giving rise to a one-parameter group as studied in [8, 9]. However, we have not explored such a possibility here.

**Proposition 1.** The nonlocal symmetry \( \Omega_4 \) reduces equation (18) to the Riccati equation \( \frac{dz}{dt} = -nz^2 \) through the reduction transformation \( z = \frac{\dot{x}}{x} + \frac{f}{n} \).

**Proof.** Let us consider the Lagrange system associated with the nonlocal symmetry \( \Omega_4 \) given by equation (31),
\[ \frac{dt}{0} = \frac{dx}{x} = \frac{d\dot{x}}{\dot{x} - \frac{x f}{n} + d}. \]  
(36)

The characteristics are \( t \) and
\[ z = \frac{\dot{x}}{x} + \frac{f}{n}. \]  
(37)

We find that the reduced equation of (18) is the following Riccati equation:
\[ \frac{dz}{dt} = -nz^2, \]  
(38)

whose general solution is given as
\[ z = \frac{1}{I_1 + nt}, \]  
(39)

where \( I_1 \) is the integration constant. \( \square \)

Substituting the above solution into (37) and rearranging, we obtain
\[ \dot{x} - \frac{x}{I_1 + nt} + x \frac{f}{n} = 0. \]  
(40)

Solving the above equation, one can find the general solution of (18). However, one finds that equation (40) can be integrated only for certain specific forms of \( f \). One such form of \( f \) for which equation (40) is integrable is \( f = kx^m \). For this choice of \( f \) and \( n = 1 \), equation (18) reduces to the generalized Emden equation [13, 20, 21]
\[ \ddot{x} + (m + 2)kx^m \dot{x} + k^2 x^{2m+1} = 0, \]  
(41)

whose general solution is obtained by integrating (40) as
\[ x(t) = \frac{I_1 + t}{\left[ I_2 + \frac{km}{m+1} (I_1 + t)^{m+1} \right]^{\frac{1}{m+1}}}. \]  
(42)

where \( I_1 \) and \( I_2 \) are the integration constants, which agrees with the known result [13]. We wish to point out here that in addition to the above nonlocal symmetries, equation (41) has
the following Lie point symmetries which can be deduced using the standard procedure, for example, using MULIE [22, 5, 6],

\[ \Omega_1 = \frac{\partial}{\partial t}, \quad \Omega_9 = t \frac{\partial}{\partial t} - \frac{x}{m} \frac{\partial}{\partial x}. \]  

(43)

Obviously the symmetry \( \Omega_9 \) is outside the scope of the above nonlocal connection (theorem 1).

(b) Example 2. Next we consider another interesting nonlinear ODE of the form

\[ \ddot{x} + c^2 x + \frac{k^2}{x^3} = 0, \]  

(44)

which arises in different areas of physics and has been studied in [13, 17, 23–25]. This equation arises in a wide variety of fields such as the study of cosmological field [26], quantum field theory in curved space [27], quantum cosmology [28], molecular structures [29, 30] and Bose–Einstein condensation [31]. Equation (44) is found to be connected to the harmonic oscillator equation

\[ \ddot{U} + c^2 U = 0, \]  

(45)

by the nonlocal transformation \( U = xe^{\int \frac{k}{x^2} dt} \). The nonlocal symmetries associated with equation (44) can be found by following the procedure discussed in section 2. Substituting the following known Lie point symmetries of the harmonic oscillator (45) into (17) [5, 6, 22],

\[ \Lambda_1 = \frac{\partial}{\partial t}, \quad \Lambda_2 = \sin 2\omega t \frac{\partial}{\partial t} + \omega U \cos 2\omega t \frac{\partial}{\partial U}, \quad \Lambda_3 = \cos 2\omega t \frac{\partial}{\partial t} - \omega U \sin 2\omega t \frac{\partial}{\partial U}, \]

\[ \Lambda_4 = U \left( \sin \omega t \frac{\partial}{\partial t} + \omega U \cos \omega t \frac{\partial}{\partial U} \right), \quad \Lambda_5 = U \frac{\partial}{\partial U}, \]

\[ \Lambda_6 = U \left( \cos \omega t \frac{\partial}{\partial t} - \omega U \sin \omega t \frac{\partial}{\partial U} \right), \]

\[ \Lambda_7 = \sin \omega t \frac{\partial}{\partial U}, \quad \Lambda_8 = \cos \omega t \frac{\partial}{\partial U}, \]  

(46)

where \( \omega = \sqrt{c^2} \), we obtain a set of first-order ODEs. Solving these first-order ODEs, with the substitution \( U = xe^{\int \frac{k}{x^2} dt} \), we obtain the following nonlocal symmetries of equation (44):

\[ \Omega_1 = \frac{\partial}{\partial t}, \]  

(47)

\[ \Omega_2 = \sin 2\omega t \frac{\partial}{\partial t} - 2\omega x e^{2k \int \frac{k}{x^2} dt} \int \alpha_1 e^{-2k / x^2} (dr) \frac{\partial}{\partial x}, \]

(48)

\[ \Omega_3 = \cos 2\omega t \frac{\partial}{\partial t} + 2\omega x e^{2k \int \frac{k}{x^2} dt} \left( \int \alpha_2 e^{-2k / x^2} (dr) \right) \frac{\partial}{\partial x}, \]

(49)

\[ \Omega_4 = xe^{k \int \frac{k}{x^2} dt} \left[ \sin \omega t \frac{\partial}{\partial t} + e^{k \int \frac{k}{x^2} dt} \int \alpha_3 \left( e^{-k / x^2} \right) (dr) \frac{\partial}{\partial x} \right], \]

(50)

\[ \Omega_5 = xe^{2k \int \frac{k}{x^2} dt} \frac{\partial}{\partial x}, \]  

(51)
\[ \Omega_6 = xe^{i/\sqrt{c^2 t}} \left[ \cos \omega t \frac{\partial}{\partial t} - e^{i/\sqrt{c^2 t}} \int (k^2 \cos(\omega t) + x^2 \omega^2 \cos(\omega t)) \right. \\
\left. + x \dot{x} \cos(\omega t) + x^3 \dot{x} \sin(\omega t) \right] \frac{\partial}{\partial x}, \] (52)

\[ \Omega_7 = xe^{i/\sqrt{c^2 t}} \left[ \int \left( \frac{\omega}{x} \cos(\omega t) - \frac{\dot{x}}{x^2} \sin(\omega t) - k \frac{\dot{x}}{x^2} \cos(\omega t) \right) e^{-i/\sqrt{c^2 t}} dt \right] \frac{\partial}{\partial x}, \] (53)

\[ \Omega_8 = xe^{i/\sqrt{c^2 t}} \left[ \int \frac{1}{x} e^{-i/\sqrt{c^2 t}} \left( \omega \sin(\omega t) + \left( \frac{k}{x^2} + \frac{\dot{x}}{x} \right) \cos(\omega t) \right) dt \right] \frac{\partial}{\partial x}, \] (54)

where

\[ \alpha_1 = \omega \sin 2\omega t + \frac{k}{x} \cos 2\omega t, \]

\[ \alpha_2 = \frac{k}{x^2} \sin 2\omega t - \omega \cos 2\omega t, \]

\[ \alpha_3 = \omega \dot{x} \cos(\omega t) - \frac{x}{x^2} \sin(\omega t) - \omega^2 x^2 \sin(\omega t) - \frac{k^2}{x^2} \sin(\omega t). \]

We also wish to point out here that in addition to the above nonlocal symmetries, equation (44) has the following three Lie point symmetries:

\[ \Omega_9 = (2 \sin^2(\sqrt{c^2 t}) - 1) \frac{\partial}{\partial t} + 2 \sqrt{c^2 x} \cos(\sqrt{c^2 t}) \sin(\sqrt{c^2 t}) \frac{\partial}{\partial x}, \] (55)

\[ \Omega_{10} = 2 \cos(\sqrt{c^2 t}) \sin(\sqrt{c^2 t}) \frac{\partial}{\partial t} + (2 \sqrt{c^2 x} \sin^2(\sqrt{c^2 t}) - \sqrt{c^2 x}) \frac{\partial}{\partial x}, \] (56)

\[ \Omega_{11} = \frac{1}{c^2} (\sin^2(\sqrt{c^2 t}) - 1) \frac{\partial}{\partial t} - \frac{\sqrt{x}}{c \sqrt{c^2 t}} \cos(\sqrt{c^2 t}) \cos(\sqrt{c^2 t}) \frac{\partial}{\partial x}. \] (57)

**Proposition 2.** The nonlocal symmetry \( \Omega_5 \) reduces equation (44) to the Riccati equation \( dz/\partial t = -z^2 + c_2 \) through the reduction transformation \( z = \dot{x}/x + k/x^2 \).

**Proof.** Let us consider the Lagrange system associated with the nonlocal symmetry \( \Omega_5 \) given by equation (51),

\[ \frac{dr}{0} = \frac{dx}{x} = \frac{d\dot{x}}{\dot{x} + \frac{k}{x^2}}. \] (58)

The characteristics of this system are \( t \) and \( z = \dot{x}/x + k/x^2 \). (59)

The reduced equation of (44) is found to be

\[ \frac{dz}{\partial t} = -z^2 + c_2. \] (60)

The general solution of the above Riccati equation is

\[ z = -\sqrt{c_2} \tan(\sqrt{c_2}(t - I_1)). \] (61)
Substituting the expression for $z$ into (59) and rearranging, we obtain
\[ \dot{x} + \sqrt{c_2} x \tan(\sqrt{c_2} t + I_1) + \frac{k}{x} = 0. \] (62)
Integrating (62), we find the general solution of (44) as
\[ x(t) = \frac{\cos(\sqrt{c_2} t + I_1)}{(I_2 - \frac{2k}{\sqrt{c_2}} \tan(\sqrt{c_2} t + I_1))^\frac{1}{2}}, \] (63)
where $I_1$ and $I_2$ are the integration constants, which agrees with the known solution [13].

2.3. Extension to more general class of second-order ODEs

The procedure described to deduce the nonlocal symmetries of equation (4) can be further extended to deduce the nonlocal symmetries of more general nonlinear ODEs of the form
\[ (D_t^2 + c_1(t) D_t + c_2(t)) g(x, t) = 0, \] (64)
where $D_t = \frac{d}{dt} + f(x, t)$. The above equation (64) is related to the following nonautonomous linear ODE:
\[ \dot{U} + c_1(t) \dot{U} + c_2(t) U = 0, \] (65)
through the nonlocal transformation
\[ U = g(x, t) e^{\int f(x, t) \, dt}. \] (66)

**Theorem 2.** Equation (64) admits a set of nonlocal symmetries which can be obtained directly from the Lie point symmetries $\xi$ and $\eta$ of equation (65).

**Proof.** From the above nonlocal transformation, we define
\[ X = \frac{\dot{U}}{U} = \frac{\ddot{g}}{g} + f(x, t). \] (67)
The above relation is a contact-type transformation using which one can rewrite equations (64) and (65) as the Riccati equation
\[ \ddot{X} + X^2 + c_1(t) X + c_2(t) = 0, \] (68)
The symmetry vector field of this equation can again be obtained by using the relation $X = \frac{\dot{U}}{U}$, and rewriting equations (9) and (11), we obtain
\[ \Lambda = \dot{\xi} \frac{\partial}{\partial t} + \left[ \eta - \frac{\eta \dot{U}}{U^2} - X \dot{\xi} \right] \frac{\partial}{\partial X} \equiv \Sigma \] (14)
and
\[ \Omega = \lambda \frac{\partial}{\partial t} + \left[ (\mu - \dot{x}_t) \frac{g_t}{g} + \mu \left( f_t + \frac{\partial}{\partial x} \frac{g_t}{g} \right) + \lambda \frac{d}{dt} \left( \frac{g_t}{g} \right) + \lambda f_t \right] \frac{\partial}{\partial X} \equiv \Xi, \] (69)
respectively. Comparing (14) and (69), we obtain
\[ \ddot{\xi} = \lambda, \quad \ddot{\eta} U - \eta \ddot{U} U^2 - f(x, t) \dot{\xi} = \mu \ddot{g}_x + \mu \left( f_x + \frac{\partial}{\partial x} \frac{g_x}{g} \right) + \frac{d}{dt} \left( \frac{\dot{g}_x}{g} \right) + \dot{\xi} f_t. \] (70)
Rewriting the second equation in (70), we arrive at the relation
\[ \frac{g_x}{g} \ddot{\mu} + \left( f_x + \frac{\partial}{\partial x} \frac{g_x}{g} \right) \mu = \frac{d}{dt} \left( \frac{\eta U}{U^2} - f(x, t) \ddot{\xi} - \frac{\ddot{g}_x}{g} - \dot{\xi} f_t. \] (71)
Substituting $U = g(x, t) e^{\int f(x, t) \, dt}$ and the point symmetries of equation (65) into the above first-order linear ODE and solving for $\mu$, we can obtain a set of nonlocal symmetries of equation (64).
3. Nonlocal symmetries: third-order ODEs

The procedure to deduce nonlocal symmetries discussed in section 2 can be straightforwardly extended to third-order ODEs. In this section, we use this procedure to deduce the nonlocal symmetries of the following class of third-order nonlinear ODEs:

\[
\ddot{x} + \frac{1}{n} \left( \left( 3nf + xf_x + 3n(n-1)\frac{\dot{x}}{x} \right) \frac{\ddot{x}}{x} \right) + (n-1)(n-2)\frac{\dot{x}^2}{x^2} + (x(3nf + xf_x) + 3n(n-1)f)\frac{x^2}{nx} + 3(nf + xf_x)f\frac{\dot{x}}{n} + \frac{x}{n}f^3 = 0.
\]  

(72)

**Theorem 3.** A class of nonlocal symmetries of the nonlinear ODE (72) can be obtained directly from the Lie point symmetries of the second-order linear ODE,

\[
\ddot{U} = 0.
\]

(73)

**Proof.** It is straightforward to check that equations (72) and (73) are connected through the nonlocal transformation

\[
U = x^n e^{\int f(\psi)\,d\psi}.
\]

(74)

From the above relation, we find \( \frac{dU}{dt} = \frac{\dot{\psi}}{n} + f \), which is the same as equation (12). Therefore, we find that the procedure discussed in section 2 can be straightforwardly applied to equation (72) as well and the nonlocal symmetries are obtained by substituting the Lie point symmetries of (73) into (17) and solving the resultant equations. □

The third-order linear ODE (73) is known to admit the following seven Lie point symmetries [5, 22, 6]:

\[
\begin{align*}
\Lambda_1 &= \frac{\partial}{\partial t}, & \Lambda_2 &= \frac{\partial}{\partial U}, & \Lambda_3 &= t^2 \frac{\partial}{\partial U}, & \Lambda_4 &= t \frac{\partial}{\partial U}, & \Lambda_5 &= \frac{\partial}{\partial U}, & \Lambda_6 &= U \frac{\partial}{\partial U}, & \Lambda_7 &= \frac{t^2}{2} \frac{\partial}{\partial t} + U \frac{\partial}{\partial U}.
\end{align*}
\]

(75)

Substituting the above Lie point symmetry vector fields into equation (17) and solving the resultant first-order linear ODEs, we find the following symmetry vector fields of equation (72):

\[
\begin{align*}
\Omega_1 &= \frac{\partial}{\partial t}, & \Omega_2 &= -x e^{-\int \frac{f}{n} \,d\psi} \int \left( x^{-(n+1)} \left( \frac{x}{n} f + x \right) e^{\int f(\psi)\,d\psi} \right) \, d\psi \frac{\partial}{\partial x}, & \Omega_3 &= x e^{-\int \frac{f}{n} \,d\psi} \int \frac{1}{nx^2} e^{\int f(\psi)\,d\psi} (2t - t^2 f - 2x^2 \frac{x}{x}) \, d\psi \frac{\partial}{\partial x}, & \Omega_4 &= t \frac{\partial}{\partial t} - x e^{-\int \frac{f}{n} \,d\psi} \int \left( f \frac{e^{\int f(\psi)\,d\psi}}{n} \right) \, d\psi \frac{\partial}{\partial x}, & \Omega_5 &= x e^{-\int \frac{f}{n} \,d\psi} \int e^{\int f(\psi)\,d\psi} (1 - t f - 2t x \frac{x}{x}) \, d\psi \frac{\partial}{\partial x}, & \Omega_6 &= x e^{-\int \frac{f}{n} \,d\psi} \frac{\partial}{\partial x}, & \Omega_7 &= \frac{t^2}{2} \frac{\partial}{\partial t} + \frac{x}{n} e^{-\int \frac{f}{n} \,d\psi} \int (1 - t f) e^{\int f(\psi)\,d\psi} \, d\psi \frac{\partial}{\partial x}.
\end{align*}
\]

(76-81)
Proposition 3. The nonlocal symmetry $\Omega_0$ reduces equation (72) to the modified Emden equation/second-order Riccati equation $\frac{d^2z}{dt^2} + 3nz\dot{z} + n^2z^3 = 0$ through the reduction transformation $z = \frac{\dot{x}}{x} + \frac{f}{n}$.

To check the above assertion, let us consider the Lagrange system associated with the symmetry $\Omega_0$ given by equation (80),
\[
\frac{dt}{0} = \frac{dx}{x} = \frac{dx}{\dot{x} - \dot{x}^2 + \frac{L}{n}}.
\]  
(82)
The characteristics of this system are $t$ and
\[
z = \frac{\dot{x}}{x} + \frac{f}{n}.
\]  
(83)
The reduced equation now turns out to be of the form
\[
\frac{dz}{dt} + 3nz\dot{z} + n^2z^3 = 0,
\]  
(84)
which is the modified Emden equation and also known as the second-order Riccati equation. Note here that equation (41) reduces to equation (84) for the choice $m = 1$. The solution of (84) can therefore be obtained from (42) with the substitution $m = 1$ and is given as
\[
z = \frac{I_1 + t}{(I_2 + I_1 t + \frac{c_1}{n})},
\]  
(85)
where $I_1$ and $I_2$ are integration constants.

Rearranging the reduction transformation with the substitution $z = \frac{I_1 + t}{(I_2 + I_1 t + \frac{c_1}{n})}$, we obtain
\[
\dot{x} = \frac{x(I_1 + t)}{(I_2 + I_1 t + \frac{c_1}{n})} + \frac{x}{n} f = 0.
\]  
(86)
We note that the above equation is integrable only for certain specific forms of $f$. We consider one such simple form for $f$ as $f = kx$. For this form of $f$, equation (72) reduces to a special case of the Chazy equation XII [13, 32–35],
\[
\ddot{x} + 4kxx\dot{x} + 3kx^2 + 6k^2x^2\dot{x} + k^3x^4 = 0.
\]  
(87)
Integrating equation (86) with $f = kx$, we obtain the general solution of (87) as
\[
x(t) = \frac{kx^2 + I_1 t + I_1 I_2}{I_1 I_3 + kl I_2 t + \frac{h}{2} t^2 + \frac{I_1 h}{2}},
\]  
(88)
where $I_1$, $I_2$ and $I_3$ are the integration constants. We wish to note that, in addition to the above nonlocal symmetries, equation (87) possesses the following Lie point symmetries also:
\[
\Omega_1 = \frac{\partial}{\partial t}, \quad \Omega_2 = x \frac{\partial}{\partial x} - t \frac{\partial}{\partial t}, \quad \Omega_3 = \frac{t^2}{2} \frac{\partial}{\partial t} + xt \frac{\partial}{\partial x} - \frac{3}{2k} \frac{\partial}{\partial x}.
\]  
(89)

3.1. More general class of third-order ODEs

In addition to equation (72), one finds a more general class of third-order ODEs of the form
\[
(D_h^6 + c_1(t)D_h^4 + c_2(t)D_h + c_3(t))g(x, t) = 0,
\]  
(90)
where $D_h = \left(\frac{d}{dt} + f(x, t)\right)$ and $c_i(t)$, $i = 1, 2, 3$, are arbitrary functions of $t$, which admits nonlocal symmetries. This class of third-order nonlinear ODEs is related to the nonautonomous third-order linear ODE of the form
\[
\ddot{U} + c_1(t)\ddot{U} + c_2(t)\dot{U} + c_3(t)U = 0,
\]  
(91)
through the nonlocal transformation \( U = g(x, t) e^{\int f(x, t) \, dt} \). In order to identify the nonlocal symmetries associated with equation (90), one can straightforwardly apply the procedure discussed in section 2.3. Substituting the point symmetries \( \xi \) and \( \eta \) of the third-order linear ODE (70) and solving, one can obtain the nonlocal symmetries of (90).

### 4. Arbitrary-order nonlinear ODEs

Having discussed the applicability of the procedure to obtain the nonlocal symmetries of certain class of second- and third-order ODEs, we extend the procedure to a class of arbitrary-order nonlinear ODEs. In this context, the following theorem holds good.

**Theorem 4.** A set of nonlocal symmetries of the mth order nonlinear ODE

\[
\left(D_m^m + c_1(t)D_m^{m-1} + \cdots + c_{m-1}(t)\right)g(x, t) = 0,
\]

where \( D_m^m = \left(\frac{d}{dt} + f(x, t)\right)^m \), can be obtained directly from the Lie point symmetries of the mth-order linear ODE,

\[
U^{(m)} + c_1(t)U^{(m-1)} + \cdots + c_{m-1}(t)U = 0,
\]

\[
U^{(m)} = \frac{d^mU}{dt^m}.
\]

**Proof.** The nonlinear ODE (92) is connected to the linear ODE (93) through the nonlocal transformation \( U = g(x, t) e^{\int f(x, t) \, dt} \). Note that this nonlocal transformation is the same as (66), connecting the second-order linear ODE (65) and the nonlinear ODE (64). Consequently, a set of nonlocal symmetries of equation (92) can be found in principle by substituting the point symmetries of the linear ODE (93) into equation (70) and solving the resultant equations, as in the case of second- and third-order nonlinear ODEs.

However, we note here that one cannot obtain all the point symmetries of the linear ODE (93) of arbitrary order \( m \). Therefore, we consider a specific parametric choice \( c_i(t) = 0, \ i = 1, 2, \ldots, m - 1 \), which reduces equation (93) to

\[
\frac{d^mU}{dt^m} = 0.
\]

Equation (94) admits at least the following two point symmetries for arbitrary order \( m \):

\[
\Lambda_1 = \frac{\partial}{\partial t}, \quad \Lambda_2 = U \frac{\partial}{\partial U}.
\]

Substituting now the nonlocal transformation \( U = g(x, t) e^{\int f(x, t) \, dt} \) into (94), we obtain the nonlinear ODE

\[
\left(\frac{d}{dt} + f(x, t)\right)^m g(x, t) = 0.
\]

Note that equation (96) is a generalization of equations (18) and (72). To identify the nonlocal symmetries of (96), we substitute the Lie point symmetries of (94) into (70). Solving the resultant equations, we deduce the following nonlocal symmetries of the nonlinear ODE (96):

\[
\Omega_1 = \frac{\partial}{\partial t} - \left[ e^{-\int f(x, t) \, dt} \int \frac{g}{g_x} \left( \frac{d}{dt} + f_t \right) \left( \frac{\partial}{\partial x} \right) e^{\int f(x, t) \, dt} \, dt \right] \frac{\partial}{\partial x},
\]

\[
\Omega_2 = \exp \left[ - \int \left( \frac{g}{g_x} \left[ f_t + \frac{\partial}{\partial x} \left( \frac{\partial}{\partial x} \right) \right] \right) \, dt \right] \frac{\partial}{\partial x}.
\]
Let us consider the specific choice $g(x, t) = x^n$, $f(x, t) = f(x)$, which reduces equation (92) to the following form:

$$\left( \frac{d}{dt} + f(x) \right)^m x^n = 0. \tag{99}$$

The above equation is a generalization of the Riccati and Abel chains. The nonlocal symmetries associated with this equation are obtained by substituting $g(x, t) = x^n$ and $f(x, t) = f(x)$ into (97) and (98) and are given as

$$\Omega_1 = \frac{\partial}{\partial t}, \quad \Omega_2 = x e^{-\int x^n f(x) \, dt} \frac{\partial}{\partial x}. \tag{100}$$

**Proposition 4.** The nonlocal symmetry $\Omega_2$ reduces equation (99) to the integrable Riccati chain $\left( \frac{d}{dt} + nz \right)^{m-1} z = 0$ through the reduction transformation $z = \frac{\dot{x}}{x} + \frac{f}{n}$.

**Proof.** Consider now the Lagrange system associated with $\Omega_2$ which is

$$\frac{dr}{dt} = \frac{dx}{x} = \frac{d\dot{x}}{\dot{x} - \frac{x^n f(x)}{n}}. \tag{101}$$

The characteristics are $t$ and

$$z = \frac{\dot{x}}{x} + \frac{f}{n}. \tag{102}$$

The reduced equation is then found to be

$$\left( \frac{d}{dt} + nz \right)^{m-1} z = 0. \tag{103}$$

We know that the Riccati chain can be integrated to obtain the general solution [13] for a specified order $m$, say $z = v(t)$. Substituting this into the reduction transformation and rearranging, we obtain

$$\dot{x} - v(t)x + \frac{x}{n}f(x) = 0. \tag{104}$$

One can obtain the general solution of (99) by solving the above first-order nonlinear ODE. Thus, we find that the problem of solving any arbitrary equation belonging to the class (99) is reduced to solving the first-order ODE (104).

5. Coupled second-order nonlinear ODEs

Having discussed the procedure for deducing the nonlocal symmetries for a class of arbitrary-order ODE, we now extend the procedure to coupled second-order ODEs. Let us consider the following system of coupled second-order ODEs:

$$\ddot{x} + (n - 1) \frac{x^2}{x} + 2\dot{x}f + \frac{x}{n} (f_x \dot{x} + f_y \dot{y}) + \frac{x}{n} f_x^2 = 0, \tag{105a}$$

$$\ddot{y} + (n - 1) \frac{y^2}{y} + 2\dot{y}g + \frac{y}{n} (g_x \dot{x} + g_y \dot{y}) + \frac{y}{n} g_x^2 = 0, \tag{105b}$$

where $f_x = \frac{\partial f}{\partial x}$, $g_x = \frac{\partial g}{\partial x}$, $f_y = \frac{\partial f}{\partial y}$, and $g_y = \frac{\partial g}{\partial y}$, which are related to the system of free particle equations

$$\ddot{U} = 0, \quad \ddot{V} = 0. \tag{106}$$
through the nonlocal transformations
\[ U = x^\theta e^{\int f(x,y)dx}, \quad V = y^\theta e^{\int g(x,y)dy}. \] (107)

Equation (105) includes the coupled modified Emden equation [14] and the coupled generalized Duffing–van der Pol oscillator equation for specific forms of \( f \) and \( g \). The integrability of equation (105) and its further generalizations have been studied in [36]. The symmetry vector field associated with the system of linear equation (106) is given by
\[ \Lambda = \xi \frac{\partial}{\partial t} + \eta_1 \frac{\partial}{\partial U} + \eta_2 \frac{\partial}{\partial V}. \] (108)

The first prolongation of this vector field is
\[ \Lambda^1 = \xi \frac{\partial}{\partial t} + \eta_1 \frac{\partial}{\partial U} + \eta_2 \frac{\partial}{\partial V} + (\dot{\eta}_1 - \dot{U}\dot{\xi}) \frac{\partial}{\partial U} + (\dot{\eta}_2 - \dot{V}\dot{\xi}) \frac{\partial}{\partial V}. \] (109)

We assume that the system of nonlinear equations (105) admits a symmetry vector field of the form
\[ \Omega = \lambda \frac{\partial}{\partial t} + \mu_1 \frac{\partial}{\partial x} + \mu_2 \frac{\partial}{\partial y} \] (110)
and its prolongation is given as
\[ \Omega^1 = \lambda \frac{\partial}{\partial t} + \mu_1 \frac{\partial}{\partial x} + (\dot{\mu}_1 - \dot{x}\dot{\lambda}) \frac{\partial}{\partial x} + (\dot{\mu}_2 - \dot{y}\dot{\lambda}) \frac{\partial}{\partial y}, \] (111)

**Theorem 5.** A set of nonlocal symmetries \( \lambda, \mu_1 \) and \( \mu_2 \) of equation (105) for the case \( f = g \) can be obtained from the point symmetries \( \xi, \eta_1 \) and \( \eta_2 \) of equation (106).

**Proof.** Using the nonlocal transformations (107), one can write the following identities:
\[ \frac{\dot{U}}{U} = n\frac{\dot{x}}{x} + f(x,y) = X, \quad \frac{\dot{V}}{V} = n\frac{\dot{y}}{y} + g(x,y) = Y. \] (112)

Using the above contact transformations, one can rewrite equations (105) and (106) in terms of the new variables \( X \) and \( Y \). The symmetry vector field of these new equations can be obtained by using the relations \( X = \frac{\dot{U}}{U}, Y = \frac{\dot{V}}{V} \) and rewriting (109) as
\[ \Lambda^1 = \xi \frac{\partial}{\partial t} + \left[ \frac{\eta_1}{U} - \eta_1 \frac{\dot{U}}{U^2} - X\dot{\xi} \right] \frac{\partial}{\partial X} + \left[ \frac{\eta_2}{V} - \eta_2 \frac{\dot{V}}{V^2} - Y\dot{\xi} \right] \frac{\partial}{\partial Y} \equiv \Sigma. \] (113)

Similarly one can rewrite (111) using the relation \( X = \frac{\dot{U}}{U} + f(x,y) \) and \( Y = \frac{\dot{V}}{V} + g(x,y) \) as
\[ \Omega^1 = \lambda \frac{\partial}{\partial t} + \left[ \mu_1 \frac{\partial X}{\partial x} + \mu_2 \frac{\partial Y}{\partial x} + (\dot{\mu}_1 - \dot{x}\dot{\lambda}) \frac{\partial}{\partial x} \right] + \left[ \mu_1 \frac{\partial Y}{\partial y} + \mu_2 \frac{\partial Y}{\partial y} + (\dot{\mu}_2 - \dot{y}\dot{\lambda}) \frac{\partial}{\partial y} \right] \equiv \Xi. \] (114)

As the symmetry vector fields \( \Sigma \) and \( \Xi \) are for the same equation, therefore the infinitesimal symmetries must also be equal. Comparing the above two equations, we obtain the following relations:
\[ \xi = \lambda, \quad n\frac{\dot{x}}{x} + \mu_1 \frac{\partial X}{\partial x} + \mu_2 \frac{\partial Y}{\partial x} = \frac{\eta_1}{U} - \eta_1 \frac{\dot{U}}{U^2} - f(x,y)\dot{\xi}, \] (115)
\[ \frac{n}{y} \frac{\dot{y}}{y} + \mu_1 \frac{\partial X}{\partial y} + \mu_2 \frac{\partial Y}{\partial y} = \frac{\eta_2}{V} - \eta_2 \frac{\dot{V}}{V^2} - g(x,y)\dot{\xi}. \] (116)
We note here that the above equations are relations connecting the known point symmetries of the linear ODEs to symmetries of the nonlinear ODEs. Solving these coupled equations, one can obtain the symmetries for the nonlocal equation. However, we find that the general solution of the above equation cannot be given for arbitrary forms of \( f \) and \( g \). The forms of \( f \) and \( g \) have to be suitably chosen to decouple the above system of equations. In order to decouple equations (115) and (116), we consider the relation

\[
\frac{U}{V} = \frac{x^n}{y^n} e^{j(f-g)z}.
\]

(117)

For the specific choice \( f = g \), the nonlocal part in the above equation vanishes and we obtain

\[
\frac{U}{V} = \frac{x^n}{y^n} = Z.
\]

(118)

The symmetry vector in terms of the new variable \( Z \) becomes

\[
\Lambda = \xi \frac{\partial}{\partial t} + \frac{1}{V} \eta_1 \frac{\partial}{\partial Z} - \frac{U}{V^2} \eta_2 \frac{\partial}{\partial Z},
\]

\[
\Omega = \lambda \frac{\partial}{\partial t} + n \mu_1 \frac{x^{n-1}}{y^n} \frac{\partial}{\partial Z} - n \mu_2 \frac{x^n}{y^{n+1}} \frac{\partial}{\partial Z}.
\]

(119)

Comparing the above two equations, we obtain

\[
\lambda = \xi, \quad \mu_1 = \frac{x}{n} \left( \frac{\eta_1}{U} - \frac{\eta_2}{V} \right) + \frac{x}{y} \mu_2.
\]

(120)

Substituting this into the symmetry determining equation (116), we obtain

\[
\mu_2 + \frac{n \mu_2}{n} \left((x+y)f_y - n \frac{\eta}{y} \right) = xy \left( \frac{\eta_2}{V} - \frac{\eta_1}{U} \right) + \frac{y}{n} \frac{d}{dt} \left( \frac{\eta_2}{V} \right) - \frac{y}{n} f(x, y) \xi.
\]

(121)

Solving the above first-order linear ODE with the substitution of the following point symmetries of the linear system (106) [5, 6, 22],

\[
\Lambda_1 = \frac{\partial}{\partial t}, \quad \Lambda_2 = \frac{\partial}{\partial U}, \quad \Lambda_3 = \frac{\partial}{\partial V}, \quad \Lambda_4 = t \frac{\partial}{\partial t}, \quad \Lambda_5 = t \frac{\partial}{\partial U}, \quad \Lambda_6 = t \frac{\partial}{\partial V}, \quad \\
\Lambda_7 = U \frac{\partial}{\partial t} - V \frac{\partial}{\partial V}, \quad \Lambda_8 = U \frac{\partial}{\partial t} + V \frac{\partial}{\partial V}, \quad \Lambda_9 = U \frac{\partial}{\partial U}, \quad \Lambda_{10} = V \frac{\partial}{\partial U}, \quad \Lambda_{11} = U \frac{\partial}{\partial U} + V \frac{\partial}{\partial V}, \quad \\
\Lambda_{12} = U \frac{\partial}{\partial t} - V \frac{\partial}{\partial V}, \quad \Lambda_{13} = t^2 \frac{\partial}{\partial t} + U t \frac{\partial}{\partial U} + V t \frac{\partial}{\partial V}, \quad \Lambda_{14} = U t \frac{\partial}{\partial U} + U^2 \frac{\partial}{\partial U} + U V \frac{\partial}{\partial V}, \quad \Lambda_{15} = V t \frac{\partial}{\partial U} + U V \frac{\partial}{\partial U} + V^2 \frac{\partial}{\partial V},
\]

(123)

one can deduce a set of nonlocal symmetries associated with the nonlinear ODE (105).

We find that equation (122) is a first-order linear ODE whose solution can be deduced straightforwardly and therefore we consider a simple case and obtain the corresponding nonlocal symmetry. For this purpose, we consider the symmetry vector \( \Lambda_{11} \) in equation (123). Substituting this into equation (122) and solving the resultant equation, we obtain

\[
\mu_2 = y e^{-\frac{1}{2} f(x+y)f_x} dt, \quad f_y = \frac{\partial f}{\partial y}.
\]

(124)

Substituting this into (121), we find \( \mu_1 \), and the symmetry vector field corresponding to \( \Lambda_{11} \) is given as

\[
\Omega_{11} = x e^{-\frac{1}{2} f(x+y)f_x} \frac{\partial}{\partial x} + y e^{-\frac{1}{2} f(x+y)f_x} \frac{\partial}{\partial y}.
\]

(125)
Proposition 5. The nonlocal symmetry $\Omega_{11}$ reduces equation (105), with $f(x, y) = g(x, y)$, to the integrable Riccati equations $\frac{dx}{dt} = -n_{1}^{2}$ and $\frac{dy}{dt} = -n_{2}^{2}$ through the reduction transformations $z_{1} = \frac{\dot{x}}{x} + \frac{1}{n} f$ and $z_{2} = \frac{\dot{y}}{y} + \frac{1}{n} f$, respectively.

Proof. The Lagrange system associated with the symmetry vector $\Omega_{11}$ is

$$\frac{dx}{t} = \frac{dy}{x} = \frac{dx}{y} = \frac{d\dot{x}}{\dot{y} - \frac{1}{n}(x+y)f_{y}} = \frac{d\dot{y}}{\dot{y} - \frac{1}{n}(x+y)f_{y}}.$$  \hspace{1cm} (126)

The characteristics of this system are $t$, $z_{1} = \frac{x}{y} + \frac{1}{n} f$ and $z_{2} = \frac{\dot{x}}{\dot{y}} + \frac{1}{n} f$, and the reduced equations become

$$\frac{dz_{1}}{dt} = -n_{1}^{2}, \hspace{1cm} \frac{dz_{2}}{dt} = -n_{2}^{2}.$$  \hspace{1cm} (127)

The solution of the above system is

$$z_{1} = \frac{1}{I_{1} + nt}, \quad z_{2} = \frac{1}{I_{2} + nt},$$  \hspace{1cm} (128)

where $I_{1}$ and $I_{2}$ are integration constants.

Substituting these into the expressions in the reduction transformations, and rearranging, we obtain

$$\dot{x} = \frac{x}{I_{1} + nt} - \frac{x}{n} f, \quad \dot{y} = \frac{y}{I_{2} + nt} - \frac{y}{n} f.$$  \hspace{1cm} (129)

We note that the above set of first-order coupled ODEs is integrable only for specific forms of $f(x, y)$. For the choice $f(x, y) = g(x, y) = a_{1}x + a_{2}y$, equation (105) reduces to the following system of coupled modified Emden-type equation [14, 36]:

$$\dot{x} + 2(a_{1}x + a_{2}y)\dot{x} + (a_{1}\dot{x} + a_{2}\dot{y})x + (a_{1}x + a_{2}y)^{2}x = 0,$$

$$\dot{y} + 2(a_{1}x + a_{2}y)\dot{y} + (a_{1}\dot{x} + a_{2}\dot{y})y + (a_{1}x + a_{2}y)^{2}y = 0.$$  \hspace{1cm} (130)

By solving the corresponding system of first-order ODEs (129), the general solution of (130) can be obtained as

$$x(t) = \frac{2I_{1}(I_{2} + t)}{a_{1}I_{1}(2I_{1} + (2I_{2} + t)\tau) + a_{2}(2I_{1} + (2I_{3} + t)\tau)},$$

$$y(t) = \frac{2I_{3}(I_{4} + (2I_{3} + t)\tau) + a_{2}(2I_{1} + (2I_{3} + t)\tau)}{a_{1}I_{1}(2I_{1} + (2I_{3} + t)\tau) + a_{2}(2I_{1} + (2I_{3} + t)\tau)},$$  \hspace{1cm} (131)

where $I_{3}$ and $I_{4}$ are two more integration constants, and the general solution agrees with the known result [14, 36].

6. Conclusion

In this paper, we have developed a new systematic procedure to deduce the nonlocal symmetries of a class of arbitrary-order nonlinear ODEs. The procedure uses the knowledge of the Lie point symmetries of the linear equations and the nonlocal transformation connecting the linear and the nonlinear ODEs. We note here that the order of the linear and the corresponding nonlinear equation remains the same. The procedure is illustrated for the second- and third-order ODEs with examples and the procedure is shown to be applicable to arbitrary-order equations as well. Using these nonlocal symmetries, we have constructed the general solution of certain specific nonlinear ODEs. We also find that an $m$th-order ODE of the form (96) with arbitrary $f(x)$ can be reduced to an $(m - 1)$th-order equation of the Riccati chain. Further, we have extended the procedure to second-order coupled ODEs and obtained the general solution of the coupled modified Emden equation using the associated nonlocal symmetries.

Appendix. Demonstration of the correctness of nonlocal symmetries

In this section, we briefly illustrate that the nonlocal symmetries obtained using the procedure discussed in section 2 indeed satisfy the invariant condition (2). In order to do so, we consider as a specific example the following nonlocal symmetry vector (29) of equation (18):

\[ \Omega_2 = \left( \frac{x^n}{n} e^{(\frac{1}{2}x \frac{d}{dx})} - \frac{1}{n^2} \int x^{1-n} f_x e^{(\frac{1}{2}x \frac{d}{dx})} dx \right) x e^{\frac{1}{2} \int s \frac{d}{ds} ds} \partial \frac{d}{dx}. \]  

(29)

The symmetry invariance condition is given as

\[ \left( \lambda \frac{\partial}{\partial t} + \mu \frac{\partial}{\partial x} + \mu^{(1)} \frac{\partial}{\partial \lambda} + \mu^{(2)} \frac{\partial}{\partial \lambda^2} \right) (\phi(x, \dot{x})) = 0, \]  

\[ \mu = \left( \frac{x^n}{n} e^{(\frac{1}{2}x \frac{d}{dx})} - \frac{1}{n^2} \int x^{1-n} f_x e^{(\frac{1}{2}x \frac{d}{dx})} dx \right) x e^{\frac{1}{2} \int s \frac{d}{ds} ds}. \]  

(A.2)

Therefore, we find that \( \mu^{(1)} = \frac{df_x}{dx} \) and \( \mu^{(2)} = \frac{df_x}{dx} \). Substituting these into the symmetry invariance condition, we find

\[ \mu = 0. \]  

(A.3)

Differentiating \( \mu \) with respect to \( t \), we find \( \mu^{(1)} \) and \( \mu^{(2)} \). Substituting these into the above equation, we find that \( \mu \) given by equation (A.2) satisfies the symmetry invariant condition (A.3). Similarly one finds that all the other remaining nonlocal symmetries of equation (18) satisfy the symmetry invariant condition.

We wish to note that the general form of the nonlocal symmetries for the class of ODEs (92) of an arbitrary finite order \( m \) is obtained by solving (71) and is given as

\[ \mu = e^p \left[ C + \oint \frac{\xi}{g} e^{-p} \left( \frac{d}{dr} \left( \frac{\eta}{g} e^{-p} \right) - \xi f_x - f \frac{\xi}{g} - \frac{d}{dr} \left( \frac{\xi g_x}{g} \right) \right) dr \right], \]  

(A.4)

where \( C \) is an integration constant, \( p = -\int \frac{\xi}{g} \left( f_x + \frac{d}{dr} \left( \frac{\xi}{g} \right) \right) dr \), and \( \eta \) and \( \xi \) are the point symmetries of the linear ODE (93). One can verify that the above-deduced general form of nonlocal symmetry satisfies the symmetry invariance condition (2) for an arbitrary finite order \( m \) as in the case of \( \Omega_2 \) above. It is also straightforward to check that the specific forms of \( \mu \) used in finding the generators \( \Omega_i \) for various examples in sections 2–5 follow from (A.4).
