Abstract

We study diffeomorphisms that have one-parameter families of continuous symmetries. For general maps, in contrast to the symplectic case, the existence of a symmetry no longer implies the existence of an invariant. Conversely, a map with an invariant need not have a symmetry. We show that when a symmetry flow has a global Poincaré section there are coordinates in which the map takes a reduced, skew-product form, and hence allows for reduction of dimensionality. We show that the reduction of a volume-preserving map again is volume preserving. Finally we sharpen the Noether theorem for symplectic maps. A number of illustrative examples are discussed and the method is compared with traditional reduction techniques.

1. Introduction

A symmetry group of a dynamical system may be discrete or continuous. The existence of discrete symmetries implies the existence of related sets of orbits and imposes constraints on bifurcations [CL00, GS02]. Continuous symmetry often results in reduction; for example, the classical results of Sophus Lie are concerned with the reduction of order of an ODE or PDE with symmetry [Olv93]. In the Hamiltonian or Lagrangian context, a continuous symmetry implies, through Noether’s theorem, the existence of an invariant, and the reduction of the dynamics by two dimensions [MR99, MMO\textsuperscript{+}07, HSS09].

In this paper, we are interested in global reduction theory for maps that have continuous symmetries. A continuous symmetry of a map $f : M \to M$ is a vector field whose flow...
commutes with the map. The set of symmetries forms a Lie algebra. Symmetry reduction for maps seems to have been first studied by Maeda [Mae80, Mae87], who showed that a map with an $s$-dimensional, Abelian Lie algebra of symmetries can be written locally in a skew-product form

$$F(\sigma, \tau) = (k(\sigma), \tau + \omega(\sigma)),$$

where $\sigma \in \mathbb{R}^{n-s}$ and $\tau \in \mathbb{R}^s$, in the neighbourhood of any point where the rank of the symmetry group is $s$.

We will show in section 2 that if the symmetry flow has a global Poincaré section $\Sigma$ that is relatively closed in a manifold $M$ (that is not necessarily compact), then we can find a covering map of the form $p : \Sigma \times \mathbb{R} \to M$. If some topological conditions are satisfied, then the map $f$ has a lift $F$ to $\Sigma \times \mathbb{R}$ with the skew-product form (1), see theorem 3. The topologies of $\Sigma$ and $M$ may constitute an obstruction for this lift to exist. We call this procedure reduction by lifting; it is a global version of Maeda’s result.

This global reduction procedure is distinct from the general local reduction method due to Palais [Pal61]. He showed that when an $s$-dimensional symmetry group has a proper action on $M$, then there is a codimension-$s$ local neighbourhood of each point, a Palais slice, such that the group orbit of a slice forms a tube within which the orbit trivializes: there are generalized ‘flow-box’ coordinates. In this paper, we are primarily concerned with one-parameter symmetry groups, though our results can be extended to the case of multi-dimensional, Abelian groups. Moreover, we will show that the reduction (1) can be obtained globally on $M$, or at least on an open, dense subset.

In the classical theory of flows with Lie symmetry groups, a flow on a manifold $M$ with symmetry group $G$ that acts properly on $M$ can be reduced to a flow on the space of group orbits, $M/G$. When the action of $G$ is free, then the group orbit space is a manifold; alternatively $M/G$ is an ‘orbifold’ and the reduction has singularities.

By contrast, in our reduction procedure, there is no need to assume that the action of the symmetry group is proper or free; it thus circumvents some of the problems with singular reduction. A number of examples are given in section 3.

One motivation of our study is to extend some results from the setting of Hamiltonian vector fields or symplectic maps to the setting of divergence-free vector fields or volume-preserving maps. Indeed, whenever a dynamical system falls into a particular structural class (symplectic, volume preserving, etc), the question arises whether the reduction by appropriate symmetries can be performed so that the structure is preserved.

We will show in section 4 that when reduction by lifting is applied to volume-preserving maps, then the reduced map $k$ of (1) is also volume preserving with respect to a natural volume form on $\Sigma$. In particular, in the three-dimensional, volume-preserving case, the reduced map $k : \Sigma \to \Sigma$ is symplectic.

As we recall in section 5, Noether’s theorem implies that whenever a Hamiltonian flow has a Hamiltonian symmetry there is an invariant, and conversely, that every invariant generates a Hamiltonian vector field that is a symmetry. This result also holds for symplectic twist maps with a Lagrangian generating function [Log73, Mae81, WM97, Man06].

We will generalize a result of Bazzani [Baz88] to show that, with the addition of a recurrence condition, Noether’s theorem also applies more generally to symplectic maps. However, it is important to note that symmetries do not generally lead to invariants nor do invariants necessarily give rise to symmetries.

In section 6 we compare our procedure with two standard reduction procedures, using as an example a four-dimensional symplectic map with rotational symmetry. We discuss the advantages and shortcomings of reduction by lifting.
2. Symmetry reduction by lifting

In this section we investigate the conditions under which a map or flow that has a symmetry can be written in the skew-product form (1). Whenever this is possible, the process reduces the effective dimension of the dynamics by one. To accomplish this reduction, we suppose that the symmetry vector field generates a complete flow that admits a global Poincaré section. We recall below the relationship between the existence of cross sections, covering spaces and fundamental groups and show how to use it to obtain the symmetry reduction.

2.1. Invariants and symmetries

We start by recalling some basic notation (see also the appendix) and facts about symmetries and invariants of vector fields and maps. We suppose that $M$ is a (not necessarily compact) $n$-dimensional, path-connected manifold and denote the set of $C^1$ vector fields on $M$ by $\mathcal{V}(M)$ and the set of $k$-forms on $M$ by $\Lambda^k(M)$. The flow, $\phi_t(x)$, of a vector field $X \in \mathcal{V}(M)$ is the solution of the initial value problem $\dot{\phi}_t(x) = X(\phi_t(x))$ with $\phi_0(x) = x$. In this paper we will assume that each vector field has a complete flow; that is, $\phi_t: M \to M$ is a diffeomorphism for all $t \in \mathbb{R}$. In this case, $\phi$ is an action of the one-dimensional Lie group $\mathbb{R}$ on $M$ with composition rule $\phi_t \circ \phi_s = \phi_{s+t}$.

An invariant for a vector field $X$ is a function $I: M \to \mathbb{R}$ such that $L_X(I) = 0$, where $L_X$ is the Lie derivative (see the appendix). Equivalently $I$ is invariant when $\phi_t^* I = I$. Similarly $I$ is an invariant for a map $f: M \to M$ if

$$f^* I := I \circ f = I.$$ (2)

A continuous symmetry of a vector field $X$ is a vector field $Y$ that commutes with $X$, $[Y, X] = 0$, or equivalently, $L_Y X = 0$. This implies that the flows of $X$ and $Y$, say $\phi$ and $\psi$ respectively, commute [Arn78, section 48]

$$\phi_t \circ \psi_s = \psi_s \circ \phi_t.$$

Similarly, a vector field $Y$ is a symmetry of a map $f$ if

$$f^* Y = Y,$$ (3)

where $f^* Y := (Df(x))^{-1} Y(f(x))$. This means that the transformation $f$ leaves the differential equation $\dot{y} = Y(y)$ invariant. Since $y$ and $z = f(y)$ satisfy the same system of differential equations, the symmetry extends to the Lie group generated by the flow of $Y$:

$$\psi_t \circ f = f \circ \psi_t.$$ Thus the map $f$ is an equivariant under the flow.

Clearly, the collection of vector fields that are symmetries of a map form a Lie algebra. For example if $X, Y \in \mathcal{V}(M)$ are symmetries of $f$, then $f^*[X, Y] = [f^* X, f^* Y] = [X, Y]$, so $[X, Y]$ is also a symmetry.

2.2. Global Poincaré sections

We will assume $f: M \to M$ is a diffeomorphism with a symmetry vector field $Y$, (3). Standing assumptions are that $M$ is an $n$-dimensional, path-connected manifold, and that $Y$ has a complete flow with a global Poincaré section $\Sigma$ that is also path-connected.

Recall that a relatively closed, codimension-one submanifold $\Sigma \hookrightarrow M$ is a Poincaré section or cross section of a flow $\psi$ if it is transverse to the flow, and is a global Poincaré section of a complete flow if every orbit of the flow has both forward and backward transversal
intersections with $\Sigma$, see the left pane of figure 1. Recall that $\Sigma$ is relatively closed in $M$ if, given a sequence in $\Sigma$ that converges in $M$, the sequence also converges in $\Sigma$.

When $\Sigma$ is a global Poincaré section for $\psi$, the first return time to $\Sigma$, $T : \Sigma \to \mathbb{R}^+$, is the smallest positive number such that for, each $\sigma \in \Sigma$, $\psi_T(\sigma) \in \Sigma$. In fact, $T$ is continuous.

The first return map $r_\psi : \Sigma \to \Sigma$, also known as the Poincaré map, is defined by

$$ r_\psi(\sigma) := \psi_T(\sigma); $$

(4)

it is a diffeomorphism. The sequence of return times $T_n$, $n \in \mathbb{Z}$, is defined so that $T_0(\sigma) = 0$,

$$ T_{n+1}(\sigma) := T_n(\sigma) + T(r_\psi^n(\sigma)), \quad n \geq 0, $$

(5)

and $T_{-n}(\sigma) = -T_n(r_\psi^{-n}(\sigma))$.

Using this notation, the iterates of the first return map are

$$ r_\psi^n(\sigma) = \psi_{T_n(\sigma)}(\sigma), $$

(6)

for all $n \in \mathbb{Z}$. Note that the sequence of return times is strictly increasing with $n$, and must be unbounded when the section $\Sigma$ is relatively closed in $M$. Indeed, if for some $\sigma_0$ the sequence $T_n(\sigma_0)$ were bounded then, since it is increasing, it would converge. Consequently, the difference $T_{n+1}(\sigma_0) - T_n(\sigma_0) \to 0$ and therefore, by definition

$$ T(r_\psi^n(\sigma_0)) \to 0, $$

as $n \to \infty$. Thus $r_\psi^n(\sigma_0) = \psi_{T_n(\sigma_0)}(\sigma_0) \to \sigma^*$ would also converge, and since $\Sigma$ is relatively closed, we could conclude that $\sigma^* \in \Sigma$. Using (5) and continuity, $T(\sigma^*) = 0$, but this contradicts the fact that the return times are always positive. A similar argument shows that $T_n(\sigma)$ is unbounded when $n \to -\infty$.

A global Poincaré section $\Sigma$ can be viewed both as a submanifold of $M$, and—as illustrated in the right pane of figure 1—as the base of a covering space for $M$. Recall that a manifold $C$ is a cover of $M$ if there is a differentiable, surjective function $p : C \to M$ such that each $m \in M$ has a neighbourhood $U$ for which $p^{-1}(U)$ is the disjoint union of a countable number of open sets in $C$, each of which is diffeomorphic, via $p$, to $U$. The covering map $p$ is necessarily a local diffeomorphism. A covering space is a fibre bundle with a discrete fibre.
We will often think of $\Sigma$ both as a submanifold of $M$ and a space in its own right. Technically, we define an inclusion map $\iota: \Sigma \hookrightarrow M$ to express the embedding, but when there is little risk of confusion, we will let $\Sigma \subset M$ denote $\iota(\Sigma)$.

A fundamental tool for the rest of the paper is the following theorem of Schwartzman that shows how global Poincaré sections are related to covering spaces.

**Theorem 1 ([Sch62]).** A relatively closed submanifold $\Sigma$ is a global Poincaré section of a flow $\psi$ on a manifold $M$ if and only if the map $p: \Sigma \times \mathbb{R} \to M$ defined by

$$\psi_\tau = \psi_x, \quad \tau = \psi_x(0),$$

is a smooth cover of $M$ with an infinite, cyclic group of deck transformations.

Recall that a deck transformation of $\Sigma$ is a deck transformation on $p$. Therefore, $\Sigma$ is little risk of confusion, we will let $\Sigma$ denote $\iota(\Sigma)$.

Proof. For any point $(\sigma', \tau') \in \text{orb}_{\Sigma}(\sigma_0, \tau_0)$, there is an $n$ such that $(\sigma', \tau') = \Delta^n(\sigma_0, \tau_0)$, and since $\Delta$ is a deck transformation, $p(\sigma', \tau') = p(\sigma_0, \tau_0) = x$. Conversely, suppose that $(\sigma', \tau') \in p^{-1}(x)$, i.e. $\psi_{\tau'}(\sigma') = x = \psi_{\tau_0}(\sigma_0)$, so that $\sigma' = \psi_{\tau_0-\tau'}(\sigma_0) \in \Sigma$. Assuming, without loss of generality, that $\tau_0 > \tau'$, then since the sequence $T_n(\sigma_0)$ is strictly increasing and unbounded, there must be an $n \in \mathbb{N}$ so that

$$T_n(\sigma_0) \leq \tau_0 - \tau' < T_{n+1}(\sigma_0).$$

If we let $\sigma_n = r_0(\sigma_0)$ and $\kappa = \tau_0 - \tau' - T_n(\sigma_0)$, then $0 \leq \kappa < T(\sigma_n)$ and $\sigma' = \psi_{\tau'}(\sigma_0)$. By definition of the first return time, the only possibility is that $\kappa = 0$. Therefore, $\tau_0 - \tau' = T_n(\sigma_0)$. Consequently, $\sigma' = r_0(\sigma_0)$ and thus $(\sigma', \tau') = \Delta^n(\sigma_0, \tau_0)$. \[\square\]

If the cover is path-connected, then the only deck transformation that has a fixed point is the identity. As a consequence, if $D$ is a deck transformation of $\Sigma \times \mathbb{R}$ then there exists $m \in \mathbb{Z}$ such that $D = \Delta^m$.

Indeed, if $y_0 \in \Sigma \times \mathbb{R}$ then, by lemma 2, there exists $m \in \mathbb{Z}$ such that $D(y_0) = \Delta^m(y_0)$. Therefore, $\Delta^{-m}D(y_0) = y_0$ and from this we conclude that $D = \Delta^m$. Hence, the collection $\{\Delta^n : n \in \mathbb{Z}\}$ is the cyclic group mentioned in theorem 1.

2.3. Symmetry reduction by lifting

We now ask whether it is possible to lift $f$ to a cover $C$ in which the map takes the skew-product form (1). Recall that a lift of $f$ is a map $F: C \to C$ such that

$$f \circ p = p \circ F.$$
In particular, any deck transformation is the lift of the identity on the base. Lifts are not unique, but all lifts are the same up to deck transformations: if \( G \) is another lift of \( f \) then \( G = \Delta^m F \) for some integer \( m \).

Suppose that \( x_0, y_0 \in C \) are two points in the cover such that \( f(p(x_0)) = p(y_0) \). A necessary and sufficient condition [Mas77, TD08] for the existence of a lift is that

\[
\psi_*(\pi_1(C, x_0)) \subseteq \psi_*(\pi_1(C, y_0)), \tag{11}
\]

where \( \pi_1(C, x_0) \) is the fundamental group of \( C \) based at \( x_0 \). In addition, if the lift exists, it can be taken to satisfy \( F(x_0) = y_0 \). In other words, each loop in \( M \) that is a projection of a noncontractable loop in \( C \) must map, under \( f \), to another loop in the same projection. This is a nontrivial requirement because \( \psi_*\pi_1(C, x_0) \) is necessarily a subgroup of \( \pi_1(M, x_0) \). Note, however, that the requirement would be trivially satisfied if the cover were simply connected, since in that case \( \pi_1(C, x_0) \) would be trivial.

The necessity of the condition (11) is easy to illustrate. Consider the example of Arnold’s cat map on the two-torus \( M = \mathbb{R}^2/\mathbb{Z}^2 \): \( f(x, y) = (2x + y, x + y) \). Does \( f \) have a lift to the cylinder \( C = \mathbb{R} \times S^1 \) with the natural covering map, \( p(z, \tau) = (z \mod 1, \tau) \)? The fundamental group \( \pi_1(M, 0) \) has two generators, say \( \gamma_1, \gamma_2 \); however, \( \pi_1(C, 0) \) has only one generator, say \( \delta \). Since \( \psi_*\delta = \gamma_2 \), and \( f_*(\gamma_2) = \gamma_1 + \gamma_2 \), the condition (11) is not satisfied. The geometric reason this fails is illustrated in figure 2. Any loop \( f \circ p \circ \delta \) has the homotopy type of \( \gamma_1 + \gamma_2 \). However, any lift of \( f \circ p \circ \delta \) can not be a loop on \( C \).

We will now give conditions for existence of a lift of \( f \) on the cover \( C = \Sigma \times \mathbb{R} \) with \( p : C \to M \) as in (7). Let \( \Psi \) denote the trivial flow on \( \Sigma \times \mathbb{R} \),

\[
\Psi_t(\sigma, \tau) = (\sigma, \tau + t). \tag{12}
\]

Clearly, \( \Psi \) commutes with \( \Delta \) and \( p \circ \Psi_t(\sigma, \tau) = p(\sigma, \tau + t) = \psi_{t*\psi}(\sigma) = \psi_t \circ p(\sigma, \tau) \) so that \( \Psi \) is a lift of \( \psi \), in the sense that each \( \Psi_t \) is a lift of \( \psi_t \), for all \( t \).

**Theorem 3 (Symmetry reduction).** Suppose that a diffeomorphism \( f : M \to M \) has a symmetry \( \psi \), with global Poincaré section \( \Sigma \) that is relatively closed in \( M \) and let \( p : \Sigma \times \mathbb{R} \to M \) be the induced cover (7). Let \( \sigma_0 \in \Sigma \) and \((\bar{\sigma}, \bar{\tau}) \in p^{-1}(f(\sigma_0))\).

\[\text{Figure 2. Failure of (11) in an attempt to construct a lift of the cat map to the cylinder.}\]
Then the following statements are equivalent.

(a) There exists a lift $F : \Sigma \times \mathbb{R} \rightarrow \Sigma \times \mathbb{R}$ of $f$ to the cover of the form

$$F : \begin{cases} 
\sigma' = k(\sigma), \\
\tau' = \tau + \omega(\sigma),
\end{cases}$$

where $k$ is a diffeomorphism of $\Sigma$, and $k(\sigma_0) = \bar{\sigma}$, $\omega(\sigma_0) = \bar{\tau}$.

(b) If $\iota : \Sigma \hookrightarrow M$ is the standard inclusion, then

$$f_* \iota_* \pi_1(\Sigma, \sigma_0) \subseteq p_* \pi_1(\Sigma \times \mathbb{R}, (\bar{\sigma}, \bar{\tau})) .$$

Proof. (a) $\implies$ (b)

By (13), $F(\sigma, 0) = (k(\sigma), \omega(\sigma))$, and since $F$ is a lift of $f$, $f(\sigma) = f \circ \iota(\sigma, 0) = p(k(\sigma), \omega(\sigma))$. Let $G : \Sigma \rightarrow \Sigma \times \mathbb{R}$ be given by $G(\sigma) := (k(\sigma), \omega(\sigma))$. Then $p \circ G = f \circ \iota$ and $G(\sigma_0) = (\bar{\sigma}, \bar{\tau})$. Consequently $f_* \iota_* \pi_1(\Sigma, \sigma_0) = p_* G_* \pi_1(\Sigma, \sigma_0)$, and since $G_* \pi_1(\Sigma, \sigma_0) \subseteq \pi_1(\Sigma \times \mathbb{R}, (\bar{\sigma}, \bar{\tau}))$, and $p_*$ is injective, this directly implies (b).

(b) $\implies$ (a) Under the condition (14), standard theorems of algebraic topology [Mas77] imply that there exists a function $G : \Sigma \rightarrow \Sigma \times \mathbb{R}$ such that $p \circ G = f \circ \iota$. Define $k$ and $\omega$ by $G(\sigma) = (k(\sigma), \omega(\sigma))$. Since $f \circ \iota(\sigma_0) = p(\bar{\sigma}, \bar{\tau}) = f(\sigma_0)$, we can take $G(\sigma_0) = (k(\sigma_0), \omega(\sigma_0)) = (\bar{\sigma}, \bar{\tau})$.

Now, for each $\tau \in \mathbb{R}$, we define $F(\sigma, \tau) := \Psi(\tau)(G(\sigma))$, where $\Psi$ is the trivial flow (12). We claim that $F$ is a lift of $f$, i.e. it satisfies (10). To show this, we note that

$$p \circ F(\sigma, \tau) = p \circ \Psi(\tau)(G(\sigma)) = \psi(\tau) \circ p(G(\sigma)) = \psi(\tau)(f(\sigma)) = f(\psi(\sigma)) = f \circ p(\sigma, \tau).$$

□

The geometry underlying the reduction (13) is illustrated in figure 3. Theorem 3 can be seen to be equivalent to a commuting diagram. Let $j : \Sigma \rightarrow \Sigma \times \mathbb{R}$ be the inclusion given by $j(\sigma) := (\sigma, 0)$. When $\iota : \Sigma \hookrightarrow M$ is the standard inclusion, then $p \circ j = \iota$. Let $\Pi : \Sigma \times \mathbb{R} \rightarrow \Sigma$ be the canonical projection. Clearly, $\Pi \circ j = \text{id}_\Sigma$. With this notation,
Theorem 3 can be represented by the commutative diagram

\[
\begin{array}{cccccc}
\Sigma & \xrightarrow{k} & \Sigma \\
\downarrow & & \downarrow \\
\Sigma \times \mathbb{R} & \xrightarrow{F} & \Sigma \times \mathbb{R} \\
\downarrow & & \downarrow \\
M & \xrightarrow{f} & M
\end{array}
\]

In particular, the reduced map \(k\) on \(\Sigma\) can be written as

\[k = \Pi \circ F \circ j.\]  

Furthermore, the choice of \(\sigma_0\) and \((\bar{\sigma}, \bar{\tau})\) such that \(f(\sigma_0) = \psi_{\bar{\tau}}(\bar{\sigma})\), fixes the choice of \(k\) and \(\omega\).

A simplification in theorem 3 occurs if \(f\) has a fixed point at a point \(\sigma_0 \in \Sigma\). Since the inclusion \(j\) induces an isomorphism of the fundamental groups, \(j_* : \pi_1(\Sigma, \sigma_0) \to \pi_1(\Sigma \times \mathbb{R}, (\sigma_0, 0)))\),

\[\iota_*\pi_1(\Sigma, \sigma_0) = p_* j_* \pi_1(\Sigma, \sigma_0) = p_* (\pi_1(\Sigma \times \mathbb{R}, (\sigma_0, 0))).\]

Upon taking \(\bar{\tau} = 0\) and \(\bar{\sigma} = \sigma_0\), the condition (14) then reduces to

\[f_* \iota_* \pi_1(\Sigma, \sigma_0) \subseteq \iota_* \pi_1(\Sigma, \sigma_0).\]  

Finally, we note a convenient equation determining \(k\) and \(\omega\) is obtained by combining the definition of the lift (10), the form of the covering map (7), and the skew-product form (13) to obtain

\[f(\psi_{\bar{\tau}}(\sigma)) = \psi_{\bar{\tau} + \omega(\sigma)}(k(\sigma)).\]

This determines \(k\) and \(\omega\) (up to the choice of lift) by the requirement that the right side must be in \(\Sigma\).

2.4. Deck symmetries and a homotopy invariant

In this section we will show that lifts of maps with symmetries have a homotopy invariant.

**Lemma 4.** Suppose that \(f\) and its lift \(F\) satisfy the hypotheses of theorem 3, and that \(\Delta\) is the deck transformation defined in (8). Then there exists \(m \in \mathbb{Z}\) such that \(F \circ \Delta = \Delta^m \circ F\) and the following identities are satisfied

\[k \circ r_\varphi = r_\varphi^m \circ k,\]

\[\omega(\sigma) - \omega(r_\varphi(\sigma)) = T_m(k(\sigma)) - T(\sigma).\]

The integer \(m\) is a homotopy invariant of the map \(f\). In addition, if \(F\) is homotopic to the identity then \(m = 1\).

**Proof.** Consider the map \(G = F \circ \Delta \circ F^{-1}\). Clearly \(p \circ G = p\), so \(G\) has to be a deck transformation. This implies that there exists \(m \in \mathbb{Z}\) such that \(G = \Delta^m\).

The integer \(m\) is independent of the choice of lift. Indeed, suppose that \(\tilde{F}\) is another lift of \(f\), then since \(p \circ F = p \circ \tilde{F}\), it follows from lemma 2 that there is an integer \(j\) such that for any \((\sigma, \tau)\), \(\tilde{F}(\sigma, \tau) = \Delta^j \circ F(\sigma, \tau)\). By continuity, \(j\) is independent of \((\sigma, \tau)\), and consequently any two lifts differ at most by a deck transformation. Thus \(\tilde{F} \circ \Delta = \Delta^{j+m} F = \Delta^m \tilde{F}\).
If $F$ is homotopic to the identity then $\Delta^{-1} \circ G$ is a deck transformation that is homotopic to the identity. The only possibility is that $\Delta^{-1} \circ G$ is the identity and therefore $m = 1$. Similarly, since the integer $m$ is independent of the lift, continuity implies any two homotopic maps will have the same value of $m$.

For the rest, it is enough to use (9) in the skew product (13). □

2.5. Reduction of flows

Theorem 3 also applies to a flow $\psi$, with a symmetry $\psi$. As in the theorem, we assume that $\psi$ has a global Poincaré section $\Sigma$.

**Corollary 5 (Symmetry reduction of flows).** Suppose that $\psi, \varphi$ are a pair of commuting flows on $M$ and that $\psi$ has a global Poincaré section $\Sigma$ that is relatively closed in $M$. Then there is a lift $\Phi_t$ of $\psi_t$ to $\Sigma \times \mathbb{R}$ of the form

$$\Phi_t(\sigma, t) = (k_t(\sigma), t + \omega(\sigma, t)). \quad (19)$$

In addition, $\Phi_t$ can be chosen to be a flow on $\Sigma \times \mathbb{R}$ and hence the functions $k_t$ and $\omega(\cdot, t)$ satisfy

$$k_{t+s} = k_t \circ k_s,$$

$$\omega(\sigma, t + s) = \omega(\sigma, t) + \omega(k_s(\sigma), s).$$

**Proof.** Just as in the definition (7) of the cover $p$, let $q : \Sigma \times \mathbb{R} \to M$ denote the map $q(\sigma, t) = \psi_t(\sigma)$. We notice that $q \circ j = p \circ j = t$. Hence for each $\sigma_0 \in \Sigma$,

$$q_*\pi_1(\Sigma \times \mathbb{R}, (\sigma_0, 0)) = q_* j_* \pi_1(\Sigma, \sigma_0) = p_* j_* \pi_1(\Sigma, \sigma_0) = p_* \pi_1(\Sigma \times \mathbb{R}, (\sigma_0, 0)).$$

Consequently, there exists a map $Q : \Sigma \times \mathbb{R} \to \Sigma \times \mathbb{R}$ such that $q = p \circ Q$. Equivalently, there exist functions $k(\sigma, t)$ and $\omega(\sigma, t)$ such that $Q(\sigma, t) = (k(\sigma, t), \omega(\sigma, t))$ and $\psi_t(\sigma) = \psi_{\omega(\sigma,t)}(k(\sigma, t))$. Denoting $k_t \defined k(\cdot, t)$, define $\Phi_t$ by (19). For each $t$, $\Phi_t$ is clearly a lift of $\psi_t$, since

$$p(\Phi_t(\sigma, t)) = \psi_{t+t\omega(\sigma, t)}(k(\sigma, t)) = \psi_t \psi_t(\sigma) = \psi_t(\sigma) = \psi_t(\psi_t(\sigma)).$$

We must show that it is possible to choose $\Phi_t$ so that $\Phi_0 = id_{\Sigma \times \mathbb{R}}$, and $\Phi_{t+s} = \Phi_t \circ \Phi_s$. Note first that $\Phi_0$ is a lift of the identity map and so it must be a deck transformation. If $\Phi_0$ is not itself the identity, then we can replace $\Phi_t$ by $\Phi_t \circ \Phi_0^{-1}$. By lemma 4, since $\Phi_t$ is a map that is homotopic to the identity, it commutes with deck transformations; thus the new $\Phi_t$ is still a lift of $\psi_t$, and satisfies $\Phi_0 = id_{\Sigma \times \mathbb{R}}$.

Now, for any $s \in \mathbb{R}$, let $G_s = \Phi_s \circ \Phi_{t-s}$. Note that $p \circ G_s = p$, so that $G_s$ is a deck transformation. Moreover, since $G_0 = id_{\Sigma \times \mathbb{R}}$, $G_s$ is homotopic to the identity, and thus must be the identity. In this way we conclude that $\Phi_t$ satisfies the group property, and is a flow. □

The implication of corollary 5 is that $k_t$ is a flow on the section $\Sigma$.

2.6. Symmetry with an invariant

Recall that generally the existence of a symmetry does not imply the existence of an associated invariant. However, it is possible that both the map and the symmetry do share an invariant. In that case, we can see that the reduced map has the same invariant.

**Lemma 6.** Suppose $f : M \to M$ is a map with a symmetry $\psi$ and the hypotheses of theorem 3 hold. If $I : M \to \mathbb{R}$ is an invariant of $f$ that is also an invariant of $\psi$, then $t^* I$ is an invariant of $k$. 

Proof. Note that $F^*p^*I = p^*f^*I = p^*I$. Moreover, for any $(\sigma, \tau) \in \Sigma \times \mathbb{R}$, (7) implies

$$p^*I(\sigma, \tau) = I(\psi_\tau(\sigma)) = I(\iota(\Sigma, \tau)) = \Pi^*\iota^*I(\sigma, \tau).$$

Using the expression (16) we can then conclude that

$$k^*\iota^*I = j^*F^*\Pi^*\iota^*I = j^*F^*p^*I = j^*p^*I = \iota^*I.$$

□

Examples that have both invariants and symmetries will be given in section 3.

2.7. Circle actions

We have assumed that the symmetry vector field $Y$ generates a flow $\psi_t$ that corresponds to an action of the Lie group $\mathbb{R}$ on the manifold $M$. However, in many cases, this action is periodic, and can thus be thought of as an action of the group $\mathbb{S}^1$ on $M$. Typically, the temporal period of the orbit of $\psi_t$ will depend upon the point. Nevertheless, if $\psi_t$ has a global section $\Sigma_1$, and every orbit is periodic, then some iterate of the Poincaré map, $r_{\psi}$, (4), must be the identity, because the flow returns to the original point on the same circle. In this case there is a smallest positive integer $\ell$ such that $r_{\psi}^\ell = id_{\Sigma_1}$, for all $\sigma \in \Sigma$.

The existence of a global section for a circle action $\psi_t$ on $M$ is a strong restriction on the topology of the manifold. Indeed, since the $\ell$th iterate of the Poincaré map is the identity, a $\mathbb{Z}/\ell \mathbb{Z}$ covering of $M$ is a trivial bundle over $\mathbb{S}^1$, i.e. $M = (\Sigma \times \mathbb{S}^1)/\mathbb{Z}/\ell \mathbb{Z}$.

In general the existence of a (free and proper) circle action gives $M$ the structure of a principal $\mathbb{S}^1$-fibre bundle, though it need not be trivial. A classical example is provided by the Hopf fibration of $\mathbb{S}^3$. At first it seems as if the reduction of theorem 3 could not be done for a symmetry that is a nontrivial bundle that is not a discrete quotient of a direct product with $\mathbb{S}^1$. However, one can often modify $M$ in a way that it acquires the necessary topology. This may be achieved by removing parts of $M$ that are invariant under the symmetry flow and under the map; examples are given sections 3 and 6. Some global topology may be lost because the modified $M$ will in general not be compact.

The question can also be inverted: how can one possibly achieve reduction and reconstruction in the case where the symmetry group action induces a nontrivial fibre bundle? The semi-direct product structure of (13) requires that the dynamics in the fibre are driven by the dynamics in the base. However, if it is not possible to globally define an origin in the $\mathbb{S}^1$ fibre, this cannot be done.

2.8. Orbit spaces and global Poincaré sections

Classical symmetry reduction begins with a smooth manifold $M$ (say without boundary, or even better a compact manifold) and a Lie group $G$ with a smooth and proper $G$-action $\Phi : G \times M \to M$. Two points on the same group orbit are now considered equivalent, and symmetry reduction means to study dynamics on the orbit space $M/G$. In general this quotient is not a manifold, but just an orbifold. Each point $x \in M$ has an associated isotropy group, namely the set of elements of $G$ that fixes $x$,

$$G_x = \{ g \in G : g(x) = x \}.$$ 

The conjugacy class of $G_x$ is called the orbit type and gives a stratification of $M$ into types. This induces a stratification of the orbit space $M/G$ with a smooth structure [Pfl01].

When the group action is free (or slightly more generally, if the isotropy group is the same for each point) the orbit space is a manifold, and $M$ has the structure of a principal bundle over the orbit space. This is the standard setting for symmetry reduction. Reconstruction, i.e. the
study of the dynamics in the fibre, may still be challenging globally because the fibre bundle may not be trivial: it may not have a global section.

Many interesting group actions are not free. When the Lie group is compact, singular reduction is still possible, where ‘singular’ reminds us that the reduced space in this case is not a manifold. The standard tool is the Hilbert basis of invariants of the group action, which together with all relations and inequalities give an accurate description of the singular reduced space, see e.g. [Cho02, PF01]. We will use this approach in passing in some of the examples in sections 3 and 6.

The principal orbit bundle (or principal stratum) is the stratum that is open and dense in \( M \) [PF01, CL00, GSS88]. Moreover, its quotient by \( G \) is connected [PF01, theorem 4.3.2]. In many cases, the isotropy group of the principal orbits is the trivial group. Within the principal stratum there is a subgroup of \( G \) that acts freely, so we return to the simpler case of a free action, albeit on the smaller space obtained by removing certain closed subsets from the original \( M \). The fact that the symmetry commutes with the map \( f \) implies that every stratum of \( M \) is a forward invariant set of \( f \). When \( f \) is invertible, this set is both forward and backward invariant, but for non-invertible maps there may be points outside the invariant set that map into it.

Hence when \( f \) is a diffeomorphism, the principal stratum is an open subset of full dimension that is invariant under \( f \). In the examples to follow, the ‘global Poincaré section’ of the symmetry is often taken to be a section on this principal stratum.

For example, consider the circle action on \( \mathbb{C}^2 \) given by

\[
G = \{ \psi_\tau(z_1, z_2) = (e^{i\tau}z_1, e^{i\tau}z_2) \mid (z_1, z_2) \in \mathbb{C}^2, \ \tau \in S^1 \}
\]

for positive integers \( l \) and \( m \). When \( l = m = 1 \) the only nontrivial isotropy group is found at the origin. The principal stratum hence is the open set \( \mathbb{C}^2 \setminus \{0\} \), on which the action of \( \psi_\tau \) is free, so that it becomes a bundle with fibre \( S^1 \). Nevertheless, the principal stratum \( \mathbb{C}^2 \setminus \{0\} \) does not have a global Poincaré section. This would imply that it is a fibre bundle with base \( S^1 \), which is impossible since every loop in \( \mathbb{C}^2 \setminus \{0\} \) is contractible. If the map preserves the ‘angular momentum’ \( L = \Im(z_1z_2) \), then the action may be restricted to the invariant level sets of \( L \). Whenever \( L \neq 0 \), this is a hyperboloid that topologically is \( \mathbb{R}^2 \times S^1 \) and there is a global section. Consequently upon removing the whole cone \( \Im(z_1z_2) = 0 \) from \( \mathbb{C}^2 \), each connected component does have a global section. Alternatively one may remove one circle from each invariant \( S^3 \) defined by \(|z_1|^2 + |z_2|^2 = \text{const}\), which turns \( S^3 \) into \( \mathbb{R}^2 \times S^1 \). Which ‘surgery’ to choose depends on properties of the map \( f \).

When \( l = 1 \) and \( m > 1 \) there is a stratum in addition to the origin given by \((0, z_2)\) with discrete isotropy group \( t = j/m, \ j = 1, \ldots, m - 1 \). If the map has this set as an invariant plane, it can be removed to give the principal stratum \( A \times \mathbb{C} \), where \( A = \mathbb{C} \setminus \{0\} \). The section \( \Im(z_1) = 0, \Re(z_1) > 0 \) has the set \( z_1 = 0 \) as an invariant boundary, and hence this section is a global Poincaré section for maps with symmetry \( \psi \). Thus we find a trivial bundle \( A \times \mathbb{C} \) with fibre \( S^1 \) and base \( \mathbb{R}^+ \times \mathbb{C} \).

When both \( l \) and \( m \) are bigger than 1 there are three strata: the origin \((0, 0)\), the plane \((0, z_2)\) and the plane \((z_1, 0)\). Removing these from \( \mathbb{C}^2 \) turns the manifold into \( A^2 \) where \( A = \mathbb{C} \setminus \{0\} \). A section along the positive real axis in either punctured plane \( A \) gives a global Poincaré section.

### 3. Examples

In this section we will give several examples to illustrate theorem 3. We start with a classical two-dimensional example.
Example (M"obius map).  An elliptic M"obius transformation is conjugate to the form
\[ f(z) = \frac{az+b}{-bz+a}, \]
for real \(a, b\) with \(ab \neq 0\). This map has fixed points at \(z = \pm i\) and is analytic on the upper half plane \(M = \{z \in \mathbb{C} : \Im(z) > 0\}\). As was noted by [Mae87], \(f\) has the symmetry \(Y = (z^2 + 1)\frac{\partial}{\partial z}\), with flow \(\psi_t(z) = \cos(t)z + \sin(t)\cos(t) - \sin(t)z\).

On \(M\) the orbits of \(\psi\) are simply circles of radius \(r\) and centre \(i\sqrt{r^2 + 1}\) for any \(r \geq 0\).

The action represented by the symmetry flow is not free, since \(z = i\) is a fixed point of \(\psi_t\).

However on the principal stratum \(M \setminus \{i\}\), the action is free, and has the global Poincaré section \(\Sigma = \{(\sigma, 0) : 0 < \sigma < 1\}\), with return time \(T = 2\pi\). Note that in order to achieve a global Poincaré section, the fixed point must be removed from the upper half plane.

To compute the reduced form (13), we use the covering (7), \(p(\sigma, \tau) = \psi_{\tau}(\sigma)\) and the notation (13), \(F(\sigma, 0) = (k(\sigma), \omega(\sigma))\) on the section, to obtain
\[ f \circ p(\sigma, 0) = f(\sigma) = \frac{a\sigma + b}{a - b\sigma}, \]
\[ p \circ F(\sigma, 0) = \psi_{\omega(\sigma)}(k(\sigma)) = \frac{\cos(\omega(\sigma)) k(\sigma) + \sin(\omega(\sigma))}{\cos(\omega(\sigma)) - \sin(\omega(\sigma)) k(\sigma)}. \]

Since, by (10), these must be equal we conclude that \(F\) takes the form
\[ F(\sigma, \tau) = (\sigma, \tau + \omega(\sigma)), \]
where \(\omega(\sigma) \equiv \omega\) is any constant such that \(\omega = \text{arg}(a + ib)\). The most natural choice may be the principal value \(\text{Arg}(a + ib) \in (-\pi, \pi]\), and each branch of arg gives a different lift. Note that both \(f\) and \(Y\) have the invariant
\[ I(z) = \frac{1}{3(z)}(|z|^2 + 1). \]

According to lemma 6, an invariant for \(k\) is naturally \(I = \sigma + \frac{1}{\theta}\), or trivially \(\sigma\) itself.

Example (Twisted symmetries).  On the manifold \(M = \mathbb{R}^2 \times (\mathbb{R}/\mathbb{Z})\), define
\[ f(\xi, z) = (R_{\beta} h(R_{-\beta} \xi), z + \alpha(|\xi|)), \]

where \(\alpha : \mathbb{R}^+ \to \mathbb{R}\), \(R_\theta \in SO(2)\) is the rotation by angle \(2\pi \theta\), and \(\beta \in \mathbb{R}\). The map \(h : \mathbb{R}^2 \to \mathbb{R}^2\) is assumed to be smooth and, so that \(f\) be continuous on \(M\), to have the symmetry
\[ h \circ R_\beta = R_\beta \circ h. \]

Note that if \(h\) were to commute with \(R_\theta\) for all \(\theta\), then \(R_{\beta} h(R_{-\beta} \xi) = h(\xi)\), so (21) would already be written in the skew-product form. Instead we assume that \(\beta\) is rational, so that the symmetry (22) is discrete.

The map (21) has the symmetry
\[ \psi_t(\xi, z) = (R_{\beta t} \xi, z + t). \]

This flow has a global Poincaré section \(\Sigma = \{\sigma, 0\} : \sigma \in \mathbb{R}^2\}\), with the covering map \(p(\sigma, \tau) = \psi_t(\sigma, 0)\). Since \(\Sigma\) is simply connected, theorem 3 implies there exits a lift \(F\) which can be easily computed using (18):
\[ F(\sigma, \tau) = (R_{-\beta t \omega(\sigma)} h(\sigma), \tau + \alpha(|\sigma|)). \]
Since $\beta = \frac{p}{q}$ is rational, then by (22) $h$ must have the associated discrete $(p, q)$ symmetry. In this case, the orbits of $\psi$ are $(p, q)$ torus knots on $M \setminus \{\xi = 0\}$. The action of the symmetry group is not free since the isotropy group of any point on the $z$-axis is different from those not on the axis. This example shows that even when the orbit space $M/G$ is not a manifold, the reduced map of theorem 3 may still be as smooth as the original map. The point is that (24) has a residual discrete symmetry with the action $g(\xi, \tau) = (R_\beta \xi, \tau)$. Factoring out this discrete symmetry would indeed lead to a singular reduced space.

An example of an orbit of the reduced map in the section $\Sigma$ is shown in figure 4, and many other examples of such maps can be constructed by replacing $h$ with any map with a discrete symmetry like those in [FG09].

Example (Non-orientable manifold). For $(\xi, z) \in \mathbb{R}^2 \times \mathbb{R}$, let $G$ be the discrete group generated by $g(\xi, z) = (-\xi, z + 1)$. Note that $G \simeq \mathbb{Z}$, and the action $(g, (\xi, z)) \mapsto g(\xi, z)$ on $\mathbb{R}^3$ is free and proper. This implies that $M = \mathbb{R}^3/G$ is a manifold; in this case $M$ is non-orientable.

Let $f : \mathbb{R}^3 \to \mathbb{R}^3$ be the map

$$f(\xi, z) = (R_{\xi + \beta/3} h \left( R_{-z/2} \xi \right), z + \beta)$$

where (as in the previous example) $R_0$ is the rotation by angle $2\pi \theta$, $h : \mathbb{R}^2 \to \mathbb{R}^2$, and $\beta \in \mathbb{R}$.

Note that since $R_{\xi + \beta/2} = -R_{\xi/2}$, $f \circ g = g \circ f$, thus $f$ can be thought of as a map on the quotient $M$.

It is easy to see that the flow

$$\psi_t(\xi, z) = (R_{t/2} \xi, z + t)$$

is a symmetry of (25). Note that $\psi_t \circ g = g \circ \psi_t$, so that $\psi_t$ defines a flow on $M$. Moreover, since $\psi_{t+1} = g \circ \psi_t$, the orbits of the symmetry $\psi$ are embedded circles in $M$, and $\psi$ has the global Poincaré section

$$\Sigma = \{(\sigma, 0) : \sigma \in \mathbb{R}^2 \} \subset M.$$
The return map for this case is simply \( r_\psi(\sigma) = \psi_1(\sigma) = -\sigma \). Computation of the reduced map using (18) gives \( F(\sigma, t) = (h(\sigma), t + \beta) \).

Note that (25) is volume preserving on \( M \) whenever \( h \) is area preserving; for example, the map

\[
h(x, y) = \left( y, \frac{2ay}{y^2 + 1} - x \right)
\]

is area preserving for any \( a \in \mathbb{R} \). This map also has the integral

\[
J(x, y) = y^2x^2 + x^2 - 2axy + y^2,
\]
i.e. one has \( J \circ h = J \). In this case the function

\[ I(\xi, z) = J(R_{-\xi/2}\xi) \]

is an integral of \( f \). Since it is also an integral of \( \psi_1 \circ \psi_1 = I \), lemma 6 implies that \( h \) has the reduced integral \( ^c I = J \), as we already knew.

**Example (Nonhyperbolic cat maps).** Suppose \( f \) is a diffeomorphism of the \( n \)-torus \( M = \mathbb{R}^n/\mathbb{Z}^n \) that fixes the origin, \( f(0) = 0 \), and is homotopic to the map \( b(\xi) = B\xi \), where \( B \in SL(n, \mathbb{Z}) \) is an \( n \times n \) unimodular matrix.

We will assume that \( B \) has a simple eigenvalue \( \lambda = 1 \) with right eigenvector \( v \) and left eigenvector \( w \). The vector field \( V = v \cdot \nabla \) generates the flow

\[
\psi_t(\xi) = \xi + tv.
\]  

(26)

In order that \( V \) be a symmetry of \( f \), condition (3) requires that \( Df(\xi)v = v \) for all \( \xi \in M \). For example, the map

\[
f(\xi) = B\xi + \phi(\xi)v,
\]

(27)

with \( \phi(0) = 0 \), is of the assumed form. It has the symmetry \( \psi_t \) if \( \phi(\xi + tv) = \phi(\xi) \), for all \( t \), so that \( D\psi_t(v) = 0 \).

Since \( w \) is a left eigenvector of \( B \), the set \( \Sigma = \{ \xi : M : w \cdot \xi = 0 \mod 1 \} \) is a codimension-one subspace invariant under \( b \) and transverse to \( v \). Indeed since \( B \) has integer coefficients, \( \Sigma \hookrightarrow M \) is a codimension-one torus; an example is sketched in figure 5. Moreover, it is clear that since \( \Sigma \) is transverse to \( v \), it is a Poincaré section for the flow (26).

Since \( f \) and \( b \) are homotopic and both fix the origin, \( f_* = b_* \), as maps on the fundamental group \( \pi_1(M, 0) \). Moreover, \( \Sigma \) is an invariant set for \( b \), so the group \( \iota_*\pi_1(\Sigma, 0) \) is invariant under \( b_* \). Consequently, \( f_*\iota_*\pi_1(\Sigma, 0) = b_*\iota_*\pi_1(\Sigma, 0) \subseteq \iota_*\pi_1(\Sigma, 0) \).

Therefore, theorem 3 and condition (17) imply that there exists a lift \( F \) of \( f \) to the cover \( \Sigma \times \mathbb{R} \) of the form of (13) with a covering map \( p : \Sigma \times \mathbb{R} \to M \) of the form \( p(\sigma, \tau) = \sigma + \tau v \).

To simplify the computations we will use an equivalent cover, \( \tilde{p} : \mathbb{T}^{n-1} \times \mathbb{R} \to M \) given by

\[
\tilde{p}(\sigma, \tau) = S\sigma + \tau v,
\]

where \( (S \mid v) \in SL(n, \mathbb{Z}) \) and the columns of the \( n \times (n - 1) \) integer matrix \( S \) form a basis for \( \Sigma \). Consequently,

\[
B(S \mid v) = (S \mid v) \begin{pmatrix} \hat{B} & 0 \\ 0 & 1 \end{pmatrix}
\]

(28)

with \( \hat{B} \in SL(n - 1, \mathbb{Z}) \). In this case, a lift of the form (13) exists and must satisfy (10). For example, a lift of (27) is

\[
P(\sigma, \tau) = (\hat{B}\sigma, \tau + \omega(\sigma)),
\]

where \( \omega(\sigma) = \phi(S\sigma) \).
An explicit case of the form (27) for $n = 3$ is

$$B = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & -4 & 4 \end{pmatrix}, \quad \text{and} \quad \phi(x, y, z) = g(x - y, y - z) \tag{29}$$

for a function $g : \mathbb{R}^2 \to \mathbb{R}$ such that $g(0) = 0$. Note that 1 is an eigenvalue of $B$ with right and left eigenvectors $v = (1, 1, 1)$ and $w = (-1, 3, -1)$, respectively. Thus the two-torus,

$$\Sigma = \{(x, y, z) \in M : x - 3y + z = 0 \mod 1\}, \tag{30}$$

shown in figure 5, is invariant under $b$ and is a global Poincaré section for the flow (26).

Moreover, since $D\phi v = 0$, the map $f$ has symmetry (26).

The fundamental group of $\Sigma$ is generated by the loops $\eta_1(t) = (2t, t, t)$ and $\eta_2(t) = (t, t, 2t)$. Setting $u_i = \iota_\ast[\eta_i]$ for $i = 1, 2$, it is easy to verify that $f_*u_1 = u_2$ and $f_*u_2 = -u_1 + 3u_2$. Consequently, theorem 3 implies there exists a lift of $f$ of the form (13). Indeed, the covering map

$$\tilde{p}(\sigma, \tau) = \begin{pmatrix} 2 & -1 & 1 \\ 1 & -1 & 1 \\ 1 & -2 & 1 \end{pmatrix} \begin{pmatrix} \sigma_1 \\ \sigma_2 \\ \tau \end{pmatrix}$$

gives $(\sigma_1, \sigma_2, \tau) = (x - y, y - z, -x + 3y - z)$, so that $\tau = 0$ corresponds to $\iota(\Sigma)$. Upon computing $\tilde{B}$ from (28), the lift takes the form (13) with

$$k(\sigma) = \begin{pmatrix} 0 & 1 \\ -1 & 3 \end{pmatrix} \sigma,$$

$$\omega(\sigma) = g(\sigma_1, \sigma_2).$$

Since the eigenvalues of $k$ are $\gamma^{\pm 2}$ where $\gamma$ is the golden mean, the reduced map is an Anosov diffeomorphism.

Note that the one cannot freely replace (30) with any global section of (26) and still satisfy the topological requirement (11). For example, the torus $\tilde{\Sigma} = \{(0, y, z) \in M\}$ is also a global section for (26). However, the map $h(\xi) = B\xi$ takes the generators $[(0, t, 0)]$ and $[(0, 0, t)]$ of the fundamental group of $\tilde{\Sigma}$ into $[(t, 0, -4t)]$ and $[(0, t, 4t)]$, violating (11).
Example (Resonant circle action). The flow \( \psi_t(z_1, z_2) = (e^{i\omega t} z_1, e^{i\omega t} z_2) \) of (20) corresponds to a circle action on \( M = \mathbb{C}^2 \) and is familiar from the study of resonant, coupled oscillators. As already noted in section 2.8 the action (20) is not free: it has a fixed point at \((0,0)\) and points with nontrivial, discrete isotropy for each point \((z_1, 0)\) whenever \( l > 1 \) and for each point \((0, z_2)\) whenever \( m > 1 \).

The general map on \( \mathbb{C}^2 \) with the symmetry (20) can be written (see, e.g., [GSS88])

\[
\begin{align*}
    z_1' &= f_1(\rho)z_1 + f_2(\rho)z_1^{m-1}z_2', \\
    z_2' &= f_3(\rho)z_2 + f_4(\rho)z_1^{m}z_2^{-1}
\end{align*}
\]

where the \( f_j(\rho) \) are complex-valued functions of the real invariants of (20), namely

\[
\begin{align*}
    \rho_1 &= z_1\bar{z}_1, \\
    \rho_2 &= z_2\bar{z}_2, \\
    \rho_3 &= \Re(z_1^m\bar{z}_2^l), \\
    \rho_4 &= \Im(z_1^m\bar{z}_2^l).
\end{align*}
\]

These four invariants form a Hilbert basis: every function invariant under the action (20) is a function of \( \{\rho_1, \rho_2, \rho_3, \rho_4\} \) (see also section 6). For example, \( \det Df \) is invariant under the symmetry \( \psi_t \), and hence a function of the invariants.

As a particular example consider

\[
(z_1', z_2') = (z_1 - i\varepsilon mz_1^{m-1}z_2', z_2 - i\varepsilon l x_1^{m}z_2^{-1}).
\]

This map is, to lowest order in \( \varepsilon \), the time-\( \varepsilon \) flow of the Hamiltonian \( H = \rho_3 \), and so is approximately a four-dimensional symplectic map in \((x_1, x_2, y_1, y_2)\), up to terms of order \( \varepsilon^2 \).

The flow of this Hamiltonian has two invariants, namely \( H \) itself, and the Hamiltonian that generates the symmetry, \( \ell \rho_1 + m \rho_2 \). When \( \varepsilon \ll 1 \) these functions will be approximate invariants of the map as well.

Assuming, for concreteness, that \( m > l \gg 1 \), then since \( \psi_t \) does not act freely on \( M = \mathbb{C}^2 \), there are points with nontrivial isotropy, in particular the set \( \{(0, z_2) : z_2 \in \mathbb{C}\} \).

This set is forward invariant under both \( \psi_t \) and \( f \), and removing it from \( M \) gives the manifold \( \tilde{M} = A \times C \simeq \mathbb{R}^+ \times S^1 \times \mathbb{C} \). On this manifold \( \psi_t \) has the global Poincaré section

\[
\Sigma = \{(x_1, z_2), x_1 > 0, z_2 \in \mathbb{C}\} \subset \tilde{M}.
\]

Thus to get a global section, it is not necessary to restrict to the principal stratum, which would entail, when \( l > 1 \), the removal of the points \((z_1, 0)\) as well. On the section \( \Sigma \) these additional points are fixed under \( f \).

The restriction of \( f \) to \( \tilde{M} \) has a lift on \( \Sigma \times \mathbb{R} \) determined by (18), i.e. by the requirement

\[
e^{-i\omega}(x_1 - i\varepsilon mx_1^{m-1}z_2', z_2 - i\varepsilon lx_1^{m}z_2^{-1}) \in \Sigma.
\]

Thus \( \omega \) is determined by requiring the first component to be real and positive, and \( F \) is given by

\[
\begin{align*}
    k(x_1, z_2) &= (x_1[1 - i\varepsilon mx_1^{m-2}z_2'], e^{-i\omega}(z_2 - i\varepsilon lx_1^{m}z_2^{-1})), \\
    \omega(x_1, z_2) &= \arg(1 - i\varepsilon mx_1^{m-2}z_2').
\end{align*}
\]

Note that even though the set \( z_1 = 0 \) is forward invariant, since \( f \) is not invertible there are points that map into the invariant set. Similarly, the reduced map \( k \) has points that map into the boundary \( x_1 = 0 \) given by the solutions of \( z_2' = (i\varepsilon mx_1^{m-2})^{-1} \). The reduced map \( k \) can be extended to the excluded set \( x_1 = 0 \) by continuity, so that the pre-images of \( x_1 = 0 \) have well-defined orbits. Even so, the fibre map \( \omega \) is undefined for points that map into the set \( x_1 = 0 \) so, strictly speaking, reduction by lifting fails in this case. However, even though the fibre map is undefined for certain points, the reduced map \( k \) is well behaved.
4. Volume-preserving symmetry reduction

We will now show that, when the map $f$ and its symmetry are both volume preserving, the reduced map $k$ of (13) is also volume preserving on $\Sigma$, with respect to an appropriate volume form. This specializes theorem 3 to the volume-preserving setting. We denote the volume form by $\Omega \in \Lambda^n(M)$; by assumption, both $f$ and $\psi_t$ preserve this form, $f^*\Omega = \Omega$ and $\psi_t^*\Omega = \Omega$, respectively. Equivalently, the symmetry vector field is incompressible: $L_Y\Omega = (\nabla \cdot Y)\Omega = 0$, where $\nabla \cdot Y$ is the divergence of $Y$.

**Theorem 7.** In addition to the hypotheses of theorem 3, assume that $f$ is volume preserving and its symmetry $Y$ is incompressible. Then the reduced map $k$ of (13) preserves a volume form $\nu$ on $\Sigma$ defined by

$$v = i_Y\Omega.$$  

(32)

**Proof.** First we note that $\mu := i_Y\Omega$ is an $(n - 1)$-form on $M$. Moreover, since $\Sigma$ is a section, $Y \not\in T\Sigma$, and so $v = i^*\mu$ is non-degenerate on $\Sigma$. In addition, $d\nu = i^*d\Omega = i^*(L_Y\Omega - i_Yd\Omega) = 0$; thus $\nu$ is a volume form. Finally, from (3) we have $f^*\mu = i_Yf^*\Omega = i_Y\Omega = \mu$, so $f$ preserves $\mu$.

We now assert that, in fact,

$$\Pi^*\nu = p^*\mu,$$  

(33)

where $\Pi : \Sigma \times \mathbb{R} \rightarrow \Sigma$ is the canonical projection. To see this recall that since $p$ is a local diffeomorphism and $Y \neq 0$ everywhere, there exists a flow box [AM78] in $M$ near each point of $\Sigma$. Therefore, we can reduce the proof to the case in which $\Sigma$ is an open set in $\mathbb{R}^{n-1}$, $M$ is of the form $M = \Sigma \times \mathbb{R}$ and $p$ is the identity. If we let $(\sigma, \tau)$ be the coordinates of $M$ then, by construction, we have that $Y = \partial/\partial \tau$ and the flow on $M$ is $\psi_t(\sigma, \tau) = (\sigma, \tau + t)$. Under these coordinates, we have that $i \circ \Pi(\sigma, \tau) = (\sigma, 0)$, and the volume form can be written as

$$\Omega = \kappa(\sigma, \tau)d\sigma_1 \wedge \cdots \wedge d\sigma_{n-1} \wedge d\tau.$$  

Since $\psi_t$ is volume preserving, we conclude that $\kappa(\sigma, \tau) = \kappa(\sigma, 0)$, for all $(\sigma, \tau) \in M$. This implies that $\mu = i_Y\Omega$ does not depend on $\tau$ and therefore $p^*\mu = (i \circ \Pi)^*\mu = \Pi^*\nu$, which is equality (33).

Finally from the definition (16) of $k$, and the fact that $\Pi \circ j = id_\Sigma$, we obtain that

$$k^*\nu = j^*F^*\Pi^*\nu = j^*F^*p^*\mu = j^*p^*f^*\mu = j^*p^*\mu = j^*\Pi^*\nu = \nu.$$  

In this way, we conclude that $\nu$ preserves $\nu$. \hfill $\Box$

Theorem 7 can be combined with corollary 5 to show that $\nu$ is a reduced volume form for an incompressible vector field with an incompressible symmetry.

**Corollary 8.** Suppose that $X, Y \in \mathcal{V}(M)$ are incompressible, commuting vector fields and that $Y$ has a flow $\psi$ with a global Poincaré section $\Sigma$ that is an immersed manifold $\iota : \Sigma \hookrightarrow M$. Then there exists a vector field $K$ on $\Sigma$ and a function $\xi : \Sigma \rightarrow \mathbb{R}$, such that

$$X|_\Sigma = K + \xi \ Y|_\Sigma,$$  

(34)

where $K$ is incompressible with respect to the volume form $\nu = i_Y\Omega$ on $\Sigma$.

**Proof.** By theorem 3 the flow $\phi$ of $X$ has a lift $\Phi$ to the cover $\Sigma \times \mathbb{R}$ of the form (19). Let $K \in \mathcal{V}(\Sigma)$ denote the vector field generated by the reduced flow $k$ of $\Phi$. By theorem 7, each $k_t$ preserves the volume form $\nu$ so that $K$ is incompressible on $\Sigma$ with respect to the form in (32).
Finally, since $K$ is tangent to—and $Y$ is transverse to—$\Sigma$, the vector field $X|_\Sigma$ can be written as a linear combination of $K$ and $Y$. Indeed (19) gives
\[
\frac{\partial}{\partial t}|_{t=0} \Phi_t(\sigma, \tau) = K + \frac{\partial}{\partial t}|_{t=0} \omega(\sigma, t) \frac{\partial}{\partial \tau}.
\]
Since $Y = \frac{\partial}{\partial \tau}$ in the coordinates $(\sigma, \tau)$, this implies (34) with $\zeta(\sigma) = \omega(\sigma, 0)$. \hfill \Box

A special case of this corollary is included in a theorem of Haller and Mezic [HM98], who treated the case $M = \mathbb{R}^3$ and noted that the flow on the two-dimensional group orbit space is Hamiltonian.

Example (Volume-preserving normal form). Consider the family of volume-preserving diffeomorphisms, $f : \mathbb{T}^3 \to \mathbb{T}^3$, defined by
\[
f(x, y, z) = (x + a(y), y + z + b(y), z + b(y)).
\]
Similar maps on $\mathbb{R}^3$, arise as the normal form for a volume-preserving map near saddle-node bifurcation with a triple-one multiplier [DM08]. The map (35) has symmetries $Y = \frac{\partial}{\partial \tau}$ which generates the flow $\psi_t(x, y, z) = (x + t, y, z)$. The natural section for $\psi$ is $\Sigma = \{(0, v, w) : v, w \in \mathbb{T}^2\}$, and the corresponding covering map $p : \mathbb{T}^2 \times \mathbb{R} \to \mathbb{T}^3$ defined by $p(v, w, \tau) = \psi_\tau(0, v, w)$. The group $\pi_1(\Sigma, 0)$ is generated by the equivalence classes $\gamma_1 = [(0, 0, t)]$ and $\gamma_2 = [(0, 0, t)]$. Since $a$ and $b$ are a periodic functions,
\[
f_{\gamma_1}(\gamma_1) = \gamma_1, \quad f_{\gamma_2}(\gamma_2) = \gamma_1 + \gamma_2.
\]
If we assume that $a(0) = b(0) = 0$, $f$ fixes the origin, and then the requirement (17) holds.

Of course (35) is already in skew-product form, with $\tau = x$, and $\omega(v, w) = a(v)$, and the reduced map becomes $k(v, w) = (v + w + q(v), w + q(v))$. The latter is a generalized Chirikov standard map and is typically chaotic.

Note that if $a(y) = y$ the topological condition would fail for any choice of section. One way to see this is to note that the linear part of the map would then be a Jordan block that does not have any 2-dimensional invariant subspaces. Another is to note that lifting with the natural section would give $\omega(u, v) = u$, which is not a continuous function from $\mathbb{T}^2 \to \mathbb{R}$. Finally, one might think that this problem could be repaired by first lifting $f$ to the universal cover $\mathbb{R}^3$, eliminating the topological requirement. However, in this case almost all orbits of the linear map are unbounded—there is no return map to any surface.

Example (4D volume-preserving map). Consider a map $f = T_2 \circ T_1$ of $\mathbb{R}^4 \simeq \mathbb{C}^2$ with coordinates $(z_1, z_2, \bar{z}_1, \bar{z}_2)$ given by the composition of the two ‘shears’
\[
T_1(z_1, z_2) = \left( z_1(a + i\sqrt{c_1 - a^2} + h_1(z_2\bar{z}_2)/(z_1\bar{z}_1)), z_2 \right)
\]
\[
T_2(z_1, z_2) = \left( z_1, z_2(b + i\sqrt{c_2 - b^2} + h_2(z_1\bar{z}_1)/(z_2\bar{z}_2)) \right),
\]
where $a, b, c_1, c_2$ are real constants, and $h_1$ and $h_2$ are non-negative real functions. Each of the shears has constant Jacobian $c_1$, so $Df = c_1 T_1$. Thus if $c_1c_2 = 1$, $f$ is volume preserving. If $c_1 = c_2 = 1$ the map $f$ is the composition of two symplectic maps.

Each shear commutes with the two symmetries $\psi_t(z_i) = e^{it}z_i$. Taken together this implies that $f$ has a pair of commuting symmetries, i.e., is equivariant under the $\mathbb{T}^2$ action $\psi_t(z_1, z_2) = (e^{it}z_1, e^{it}z_2)$. The reduction of theorem 7 can be carried out recursively, thus reducing $f$ to an area-preserving map.

To construct a global section, we must construct the sets of nontrivial isotropy from $M$: removing the fixed sets $z_1 = 0$ and $z_2 = 0$ leaves $A^2 = (\mathbb{C} \setminus \{0\})^2$. On this set there is a global
Symmetry reduction by lifting for maps

Poincaré section for the two-parameter action, $\Sigma = \{(x_1, x_2) : x_i > 0\} \subset A^2$. The result of the reduction is to simply introduce polar coordinates in both complex planes, and give a fibre map with $-\omega = (\arg(z'_1), \arg(z'_2))$.

The reduced map $k$ would be written in terms of $(x_1, x_2) \in \Sigma$. Instead, we use the two invariants $\rho_1 = z_1\bar{z}_1$ and $\rho_2 = z_2\bar{z}_2$ of the symmetry as coordinates to give

$$T_1(\rho_1, \rho_2) = (c_1\rho_1 + h_1(\rho_2), \rho_2) = (\rho'_1, \rho_2).$$

A similar result holds for $T_2$, so that the reduced area-preserving map (assuming $c_1c_2 = 1$) is

$$T_2(T_1(\rho_1, \rho_2)) = (c_1\rho_1 + h_1(\rho_2), c_2\rho_2 + h_2(\rho'_1),$$

which is smooth even for $\rho_j = 0$.

5. Noether symmetries

For Hamiltonian flows and symplectic maps the close relationship between the existence of invariants and symmetries is well known. Noether’s theorem, for example, implies that a Lagrangian system with a symmetry acting in configuration space has an invariant. Such a relationship is exploited in the Liouville–Arnold construction of action-angle variables for an integrable $n$-degree-of-freedom Hamiltonian where each invariant generates a symmetry vector field. In this case, the involutive property of the invariants implies that the corresponding symmetry vector fields commute.

As we remarked in the introduction, analogues of Noether’s theorem do not exist for maps in general nor for volume-preserving maps in particular. For example the skew product $f(x, y, \tau) = (k(x, y), \tau + \omega(x, y))$ on $\Sigma \times S^1$ has the obvious symmetry $Y = \partial/\partial \tau$ and preserves the volume form $\Omega = dx \wedge dy \wedge d\tau$ whenever $k$ is area preserving. If $k$ has no invariant, then neither does $f$. This would occur, e.g. when $\Sigma = T^2$, and $k(x, y) = (2x + y, x + y)$, the cat map.

In addition, a three-dimensional map could have an invariant, restricting its orbits to two-dimensional level sets, and yet have no symmetry: the map can be chaotic on the level sets. Examples include the trace maps [RB94], such as the Fibonacci map

$$f(x, y, z) = (y, z, -x + 2yz).$$

Trace maps are volume preserving; many similar examples were also given in [GM02]. Consequently, symmetries do not necessarily give rise to invariants without some additional structure.

One sufficient additional structure corresponds to symplectic maps with Hamiltonian symmetries. A symmetry $Y$ that is a Hamiltonian vector field is known as a Noether symmetry. Here we give a slight generalization of a theorem of [Baz88, appendix 1], which required the symplectic map to be a twist map. We show that one can drop this requirement if the map has a mild recurrence property.

Theorem 9 (Symplectic Noether). If a symplectic map $f$ has a Noether symmetry and a recurrent orbit, then $f$ has an invariant. Conversely if a symplectic map $f$ has an invariant $I$, then the Hamiltonian vector field of $I$ is a symmetry of $f$.

Proof. For this proof let $\mu$ denote the symplectic form (e.g. $\mu = dq \wedge dp$), and let $I$ be the Hamiltonian of the vector field $Y$: $i_Y \mu = dI$. Consequently $f^*i_Y \mu = d(f^*I)$, but by the symmetry and symplectic conditions $f^*i_Y \mu = i_{f^*Y} f^* \mu = i_Y \mu = dI$. Consequently
\( \text{d}(f^*I - I) = 0 \), so that \( I(f(x)) = I(x) + c \) for some constant \( c \). Suppose \( x^* \) is a recurrent point, then there exists a subsequence \( t_i \to \infty \) such that \( f^{t_i}(x^*) \to x^* \). However, since \( I(f^i(x)) = I(f^{i-1}(x)) + c = \cdots = I(x) + tc, \) this implies that

\[
\lim_{i \to \infty} [I(f^{t_i}(x^*)) - I(x^*)] = \lim_{i \to \infty} t_i c = 0,
\]

so that \( c = 0 \). Thus \( I \) is an invariant for \( f \). Conversely, if the symplectic map \( f \) has an invariant \( I \), then \( I \) generates a Hamiltonian vector field \( Y \), and

\[
\iota_Y \mu = f^*(\iota_Y \mu) = f^*(dI) = d(f^*I) = dI = \iota_Y \mu.
\]

Thus \( \iota_Y \mu = 0 \), but since \( \mu \) is non-degenerate, this can only occur when \( f^*Y = Y \). \( \square \)

The condition that \( f \) has a recurrent orbit is necessary. The map \( f(x,y) = (x+c, y+g(x)) \), on \( \mathbb{R}^2 \) is symplectic with the canonical form \( dx \wedge dy \) and has the translation symmetry \( \partial / \partial y \). This symmetry is generated by the Hamiltonian \( I(x,y) = x \), which, however, is not an invariant for \( f \) for any \( c \neq 0 \). Note that \( f \) has no recurrent orbits. By contrast, if we take the same \( f \) but suppose that it is a map on \( S^1 \times \mathbb{R} \), then \( f \) may have recurrent orbits, but the symmetry vector field \( \partial / \partial y \) is locally, but not globally Hamiltonian, and so does not generate an invariant.

**Example (Lyness map).** For any \( a > 0 \), the Lyness map \([Lyn45]\),

\[
f(x,y) = \left( y, \frac{a + y + x}{x} \right)
\]

is a diffeomorphism on the positive quadrant \( M = \mathbb{R}_+^2 \) that preserves the symplectic form \( \mu = \frac{1}{xy} dx \wedge dy \). It has the symmetry \([BC98]\)

\[
Y = xy(-\partial_x I, \partial_y I) = -xy \frac{\partial I}{\partial y} \frac{\partial}{\partial x} + xy \frac{\partial I}{\partial x} \frac{\partial}{\partial y},
\]

where

\[
I = \frac{(1+x)(1+y)(a + x + y)}{xy}.
\]

The function \( I \) is an invariant for \( f \). Moreover, \( Y \) is the Hamiltonian vector field of \( I \) with respect to \( \mu \) and so \( I \) is an invariant for \( Y \). This is in agreement with theorem 9.

The level sets of the invariant \( I \) for \( I > I_{\text{min}} = I(x^*, x^*) \) are topologically circles that intersect the line \( \Sigma = \{(\sigma, \tau) : \sigma > x^* \} \) with \( x^* = \frac{1}{4}(1 + \sqrt{1 + 4a}) \) exactly once. The symmetry is not free since the fixed point \((x^*, x^*)\) has nontrivial isotropy. However, on the principal stratum \( \tilde{M} = M \setminus \{(x^*, x^*)\}, \) \( \Sigma \) is a global Poincaré section for the flow of \( Y \).

Given that \( \Sigma \) is simply connected, \( f \) can be reduced with a lift. The lifted map on \( \Sigma \times \mathbb{R} \) is \( F(\sigma, \tau) = (\sigma, \tau + \omega(\sigma)) \). An integral expression for \( \omega(\sigma) \) can be obtained from the results in \([BC98]\).

In the next section, we will apply these results to a four-dimensional symplectic map.

### 6. Comparison of reduction methods

In this section, we will illustrate three different approaches to reduction, namely

- invariants,
- polar coordinates and
- reduction by lifting.
We will use, as an example, a four-dimensional symplectic map with a rotational symmetry. A symplectic map on $M = \mathbb{R}^4 \cong \mathbb{C}^2$ of standard type with a symmetry can be constructed using the Lagrangian generating function $S(z, z') = \frac{1}{2} |z - z'|^2 - W(z\bar{z})$ with $z = x + iy \in \mathbb{C}$ and $W : \mathbb{R} \to \mathbb{R}$ a $C^2$-function. This generating function is invariant under the rotation $(e^{ir}z, e^{ir}z')$. Introducing the conjugate momenta $w = \rho_x + i\rho_y$, then the corresponding 4D map, generated by $w = -\partial_z S$ and $w' = \partial_{z'} S$, is

$$f(z, w) = (z', w') = \left(z + w' - zV(z\bar{z})\right)$$

where $V(x) = \frac{d}{dx} W(x)$. The map (37) has the symmetry $\psi_t(z, w) = (e^{it}z, e^{it}w)$, e.g., the flow (20) with $k = l = 1$. Note that $\psi_t$ is symplectic and is the flow of the ‘angular momentum’ Hamiltonian, $L = \Im(\bar{z}w)$. The discrete Noether theorem, theorem 9, implies that $L$ is an invariant of $f$ as well.

**Reduction using invariants.** Since the symmetry $\psi_t$ is a special case of (20), the basis (31) with $(z_1, z_2) \to (z, w)$ and $k = l = 1$ generates its real polynomial invariants. Note that these $\rho_i$ are not independent: they obey the relation

$$\rho_3^2 + \rho_2^2 = \rho_1 \rho_2,$$

and the inequalities

$$\rho_1 \geq 0, \quad \rho_2 \geq 0.$$

The map $(z, w) \to (\rho_1, \rho_2, \rho_3, \rho_4)$ is called the *Hilbert map*. Rewriting (37) in terms of the invariants gives

$$\rho_1' = \rho_1(1 - V)^2 + \rho_2 + 2\rho_3(1 - V),$$

$$\rho_2' = \rho_2 - 2\rho_3 V + \rho_1 V^2,$$

$$\rho_3' = \rho_3 - \rho_1 V + \rho_2,$$

where $V = V(\rho_1)$ and $\rho_4 = -L$, the negative of the constant angular momentum. The map (39) is volume preserving with respect to the form $\Omega = dp_1 \wedge dp_2 \wedge dp_3$ on $\mathbb{R}^3[\rho_1, \rho_2, \rho_3]$ and has an invariant $\rho_2^2 = \rho_1 \rho_2 - \rho_3^2$ inherited from the relation (38).

The Hilbert coordinates satisfy the Poisson structure given by $\{\rho_1, \rho_2\} = 4\rho_3, \{\rho_1, \rho_3\} = 2\rho_1, \{\rho_2, \rho_3\} = -2\rho_2$ with Casimir $\rho_1 \rho_2 - \rho_3^2$. Moreover, the reduced mapping (39) is a Poisson map: it preserves this reduced Poisson structure. The level set of the Casimir is a smooth submanifold provided $\rho_4 \neq 0$. On each such a level set (a smooth symplectic leaf) the map is area preserving. The reduction by the symmetry and by its generating invariant reduces the dimension of the map by two.

However, the invariant set $\rho_4 = 0$ is a half-cone. This case is a singular reduction, because the action $\psi_t$ is not free, since the origin $(z, w) = (0, 0)$ is a fixed point for the whole group.

From this construction, the map in the symmetry direction, in the form $\tau' = \tau + \omega(\rho_3)$, can be obtained as follows. The Hilbert map from full phase space $T^*\mathbb{R}^2$ to the invariants is not invertible. It has the symmetry orbits as fibres. As pre-image in the fibre we can choose

$$(z, w) = h(\rho) =: \left(\sqrt{|\rho_1|}, \sqrt{|\rho_2|} \exp(i\arg(\rho_3-i\rho_4))\right).$$

The angle increment $\omega$ is now defined by $f(h(\rho)) = \psi_\omega h(\rho')$. The explicit form of the fibre map therefore is found from $z' = e^{i\omega} \rho_3$ so that $\omega = \arg(z')$. The map $h$ is not defined when $\rho_3 = \rho_4 = 0$, i.e., at the origin of the $z$-plane and at the origin of the $w$-plane.
Reduction using polar coordinates. Polar coordinates appear whenever the symmetry angle \(\theta\) becomes a coordinate. There is a unique extension of this transformation of coordinates to a symplectic transformation of all of phase space that is linear in the momenta, the so-called cotangent lift, see, e.g., [AM78]. Denoting the new variables by \((r, \theta, p_r, p_\theta)\), the momentum \(p_\theta\), conjugate to \(\theta\), becomes the conserved quantity. Specifically set \(z = re^{i\theta}\) with cotangent lift \(w = e^{i\theta}(p_r - ip_\theta/r)\) and rewrite the map in the new coordinates \((r, \theta, p_r, p_\theta) = (\sqrt{z^2}, \arg z, \Re(z\bar{w})/r)\).

Having done most of the work in for the Hilbert basis already, we proceed as follows. In terms of the invariants, the polar coordinates are \((r, p_r, p_\theta) = (\sqrt{\rho_1^2}, \rho_3/\sqrt{\rho_1}, \rho_4)\) and the map is obtained from that of the invariants by eliminating \(\rho_2\) using \(\rho_2 = (\rho_1^2 + \rho_3^2)/\rho_1 = p_r^2 + p_\theta^2/r^2\).

This gives an area-preserving map that depends on the parameter \(p_\theta\)

\[
\begin{align*}
r' &= \left(\frac{p_\theta^2}{r^2} + (r + p_r - rV)^2\right)^{1/2}, \\
p_r' &= (r^2 - r(r + p_r - rV))/r', \\
p_\theta' &= \frac{\rho_1^2}{\rho_2} + \frac{\rho_3^2}{\rho_4},
\end{align*}
\]

where \(V = V(r^2)\). The fibre map is obtained from rewriting \(z' = z + w' = z + w - zV\) in polar coordinates, hence \(r'e^{i\theta'} = e^{i\theta}(r + p_r - ip_\theta/r - rV)\) and therefore

\[
\theta' = \theta + \arg(r + p_r - rV - ip_\theta/r).
\]

This map works well unless \(r' = 0\), which makes \(p_r'\) and \(\theta'\) undefined. Points with \(r' = 0\) can only be reached when \(p_\theta = 0\), and then this can happen whenever \(r + p_r = 0\). Excluding \(p_\theta = 0\) gives a well-defined, smooth map.

Reduction by lifting. For reduction by lifting we need to find a global Poincaré section of the symmetry flow \(\psi\). As a first attempt try the surface defined by\(\Re(z) = 0\) for \(x = \Re(z) > 0\). The flow is tangent to the section when \(\Re(z) = 0\), hence all of the plane \([z = 0]\) is tangent to the section. Unfortunately, this plane of tangency is not invariant under the map. In order to avoid this difficulty, we can choose a larger invariant set that contains the tangency set, and restrict the map to the complement of this set.

The angular momentum \(L(z, w) = \Re(z\bar{w}) = \Im(\bar{z}w)\) is invariant both under the flow and the symplectic map. Note that the plane \([z = 0]\) is contained in the invariant level set \([L(z, w) = 0]\). The manifold \(M = \{L(z, w) = 0\}\) has two connected components,

\[
M^+ = \{(z, w) \in \mathbb{C} \times \mathbb{C} : L(z, w) > 0\},
\]

and the corresponding negative angular momentum set. As the analysis for either component is the same, we will now restrict the map \(f\) and the flow \(\psi\) to \(M^+\). The symmetry flow as a global Poincaré section on \(M^+\):

\[
\Sigma = \{(x, w) \in M^+ : x > 0\}.
\]

This section is a codimension-one, embedded submanifold that is relatively closed in \(M^+\). Moreover, if \((x, w) \in \Sigma\) then \(\Im(w) > 0\).

We know that the lift of \(f\) is of the form \(F(\sigma, \tau) = (k(\sigma), \tau + \omega(\sigma))\). Taking a point \(\sigma = (x, w) \in \Sigma\) we can compute its image under (37) to obtain

\[
f(x, w) = (x + xV(x^2), w - xV(x^2)).
\]

By (18), this equals \(\psi_{\omega/2}(k(\sigma))\), so that \(e^{-i\omega(x + w - xV)}\) must be real and positive (where \(x\) is assumed positive). Noting that \(\Im(x + w - xV) > 0\), this immediately gives \(\omega(\sigma) = \arg(x + w - xV)\), and we can choose the branch so that \(0 < \omega(\sigma) < \pi\). The reduced map thus becomes

\[
k(x, w) = ((x + w - xV), e^{i\omega(x, w)}(w - xV)).
\]

By (32), \(k\) preserves the volume form \(v = p_x \, dx \wedge dp_x \wedge dp_y\).
Because we started with a symplectic map the reduced map has an invariant, \( \iota^* \mathfrak{S}(\bar{z}w) = x \mathfrak{S}(w) = xp_x = p_0 \). If we were to eliminate \( p_y \) by fixing the invariant, we would again obtain the polar coordinate map (40).

Comparison. The Hilbert map is similar to what we call the projection \( \Pi \) to the section \( \Sigma \), while its ‘inverse’ \( h \) is like the inclusion map \( \iota \). In differential geometry, a fibre bundle is said to have a ‘global section’ if \( h \) is continuous. Note, however, that the Hilbert map has fibre \( S^1 \), while when we construct the global Poincaré section we have a bundle with base \( S^1 \) and fibre \( \Sigma \) [BDW96]. In fact, as pointed out in section 2.7, some finite covering of the bundle is a direct product with \( S^1 \). In the present example the manifold \( M^* \) is topologically a direct product \( S^1 \times \mathbb{R} \times \mathbb{R}^+ \).

The Hilbert map may be applied to points with isotropy where projection to \( \Sigma \) is not defined. The reduced map (39) is well-defined, even when the \( S^1 \)-bundle does not possess a global section or when there is no global Poincaré section. Reduction by lifting is more efficient in that one does not need to introduce extra coordinates; moreover, one does not need to know the ‘good’ coordinate system to do the reduction. Instead the choice of global Poincaré section defines such a coordinate system, and the reduction is obtained by a topological lift to a natural cover that exists whenever this section is relatively closed in the manifold.

7. Conclusions

We have studied maps with continuous symmetries, specializing to the case that the symmetries have a global Poincaré section. We showed in theorem 3 that if a necessary topological condition is satisfied, then the map has a lift and there are coordinates for which the lift has the skew-product form (13). We called this ‘reduction by lifting’ because the map on the section—the reduced map \( k \)—describes the dynamics modulo the symmetry. The fibre map, which corresponds to a translation, is obtained naturally from the symmetry flow.

The topological conditions for the existence of a lift require that the homotopy homomorphism induced by the map leaves the fundamental group of the Poincaré section invariant. This requirement is trivial if the section is simply connected. In principle, the restriction could be avoided if one first lifts the dynamics to the universal cover; however—as we saw in an example—almost all orbits may become unbounded. In many cases, a minimal lift using only the symmetry flow seems more useful.

If the map and its symmetry are volume-preserving, then the reduced map is also volume-preserving as shown in theorem 7. If both the map and its symmetry preserve an invariant, then the reduced map also has an invariant, recall lemma 6. Finally, if the map and its symmetry are symplectic, then, as in Noether’s theorem, the existence of a symmetry implies an invariant, providing the map has a recurrent orbit, recall theorem 9.

A number of examples were given to compare and contrast reduction by lifting to standard reduction techniques. Reduction by lifting is more parsimonious than the Hilbert mapping technique, which can result in a high-dimensional map that must satisfy a number of constraints. It is more explicit than the standard reduction by group orbit technique, and moreover applies when the action of the symmetry is neither proper nor free. When the action is not free, reduction by lifting need not lead to a map on a singular space.

However, the existence of a global section for the symmetry flow is a strong restriction. This can be overcome in some cases, as we showed, by restriction of the dynamics to invariant strata of the symmetry flow.

Appendix. Forms and Lie derivatives

Here we set out our notation, which follows, e.g., [AMR88]. The set of \( k \)-forms on a manifold \( M \) is denoted by \( \Lambda^k(M) \), and the set of \( C^1 \) vector fields by \( \mathcal{V}(M) \). If \( \alpha \in \Lambda^k(M) \) and \( V_1, V_2, \ldots, V_k \in \mathcal{V}(M) \), then the pullback, \( f^* \), of a form \( \alpha \) by a diffeomorphism \( f \) is defined by

\[
(f^*\alpha)_x(V_1, V_2, \ldots, V_k) = \alpha_{f(x)}(Df(x)V_1(x), \ldots, Df(x)V_k(x)).
\] (42)

The pullback can be applied to a vector field \( V \) as well:

\[
(f^*V)(x) = (Df(x))^{-1}V(f(x)).
\] (43)

The push-forward operator is defined as \( f_* = (f^{-1})^* \). The interior product of \( \alpha \) with \( V \) is defined as the \((k-1)\)-form

\[
i_V \alpha := \alpha(V, \cdot, \cdot, \cdot).
\]

Suppose that \( \phi_t \) is the \( (C^1) \) flow of a vector field \( V \), so that \( \phi_0(x) = x \), and \( \frac{d}{dt} \phi_t(x) = V(\phi_t(x)) \). Then the Lie derivative with respect to \( V \) is the linear operator defined by

\[
\mathcal{L}_V(\cdot) := \frac{d}{dt} \bigg|_{t=0} \phi_t^* (\cdot)
\] (44)

where \( \cdot \) is any tensor. In particular for a vector field \( X \),

\[
\mathcal{L}_V X = [V, X]
\] (45)

is the Lie bracket. The Lie derivative acting on differential forms obeys Cartan’s homotopy formula

\[
\mathcal{L}_V \alpha = i_V (d\alpha) + d(i_V \alpha).
\] (46)
