Abstract

We study scalar-linear and vector-linear solutions of the generalized combination network. We derive new upper and lower bounds on the maximum number of nodes in the middle layer, depending on the network parameters and the alphabet size. These bounds improve and extend the parameter range of known bounds. Using these new bounds we present a lower bound and an upper bound on the gap in the alphabet size between optimal scalar-linear and optimal vector-linear network coding solutions. For a fixed network structure, while varying the number of middle-layer nodes \( r \), the asymptotic behavior of the upper and lower bounds shows that the gap is in \( \Theta(\log(r)) \).

Index Terms

Network coding, generalized combination network, vector network coding, gap size

I. INTRODUCTION

In multicast networks that apply routing, a source node multicasts information to other nodes in the network in a multihop fashion, where every node can pass on their received data. Network coding has been attracting increasing attention since the seminal papers [1], [29] which showed that the throughput can be increased significantly by not just forwarding packets but also performing linear combinations of them. Several follow-up works [13], [22], [30], [31] also showed that network coding outperforms routing in terms of delay, throughput and reliability for specific networks.

In network coding, each node is allowed to encode its received data before passing it on. We formulate the network coding problem as follows: for each node in the network, find a function of its incoming messages to transmit on its outgoing links, such that each receiver can recover all (or a predefined subset of all) the messages. We say a network is solvable if such a function exists. The encoding at relay nodes incurs delay and memory cost in the network. One approach in minimizing these costs, is reducing the alphabet size of the coding operations, thus resulting in less complexity in practical implementations of network coding [21], [25], [27].

A. Previous Work

A considerable number of studies have been conducted on different types of network coding: such as linear network coding [24], [29] and non-linear network coding [28], deterministic network coding [34] and random linear network coding [23], [32]. In this paper, we only focus on linear network coding and discuss the performance of scalar linear network coding and vector linear network coding.

In linear network coding, each linear function for a receiver consists of coding coefficients for incoming messages. If the messages are scalars in \( \mathbb{F}_q \) and the coding coefficients are vectors over \( \mathbb{F}_q \), the solution is called a scalar linear solution. If the messages are vectors in \( \mathbb{F}^t_q \) and the coding coefficients are matrices over \( \mathbb{F}_q \), it is called a vector linear solution. Vector network coding was mentioned in [5] as fractional network coding and extended to vector network coding in [10].

Although a scalar solution over \( \mathbb{F}^t_q \) can be translated to a vector solution composed of \( t \times t \) matrices over \( \mathbb{F}_q \), directly designing codes for vector network coding still has advantages: there exist \( q^{t^2} \) many \( t \times t \) matrices over \( \mathbb{F}_q \), while a scalar solution only employs \( q^t \) of them. Therefore, vector network coding offers a larger space of choices for optimizing the performance of a network. However, not every solvable network has a vector solution [9]. The hardness of finding a capacity-achieving vector

The material in this paper will partly be presented at the 2020 International Symposium on Information Theory (ISIT).

solution for a general instance of the network coding problem was proved in [26]. In [6] it was proved that there exists a network with a vector linear solution of dimension $t$ but no vector solution over any finite field if the message dimension is less than $t$. The existence of explicit networks where scalar solutions still outperform binary vector solutions was shown in [33]. Nevertheless, a network was constructed in [33] whose minimal alphabet for a scalar linear solution is strictly larger than the minimal alphabet for a vector linear solution. The gap in the minimum alphabet size between a scalar solution and a vector solution was shown to be positive in generalized combination networks [16] and minimal multicast networks [4]. Several algorithms for deterministic networks via vector coding were presented in [10]–[12], [16].

Solving network coding problems also motivates research in other topics such as new metrics for network codes [17], subspace codes design [14], [15], [19], networks over the erasure channel [20] and distributed storage [7], [8]. More long-standing open problems can be found in [18].

B. Our Goals and Contributions

In this paper, we only consider linear solutions of networks. Denote by $\mathbb{F}_q$ a finite field of size $q$. Bold lowercase letters denote vectors and bold capital letters denote matrices.

The scalar and vector solutions stand for scalar linear and vector linear solutions throughout the rest of the paper. We call a scalar solution over $\mathbb{F}_q$ for a network, a $(q,1)$-linear solution, and we call a vector solution of length $t$ over $\mathbb{F}_q$, a $(q,t)$-linear solution.

The main object we study in this paper is the class of generalized combination networks. An $(\varepsilon,\ell)-N_{h,r,\alpha\ell+\varepsilon}$ generalized combination network is illustrated in Figure 1 (see also [16]). The network has three layers. The first layer consists of a source $x = (x_1, x_2, \ldots, x_h)$...
Our main contributions are the following:

- two upper bounds on $r_{\text{max}}$, the maximal number of nodes in the middle layer of a generalized combination network (Corollary 1 (valid only for $h \geq 2\ell + \varepsilon$) & Corollary 2 ($\alpha = 2$)),
- two lower bounds on $r_{\text{max}}$ (Theorem 3 & Corollary 3 ($h \leq 2\ell + \varepsilon$)),
- an upper bound on the gap in the minimum alphabet size for any fixed generalized combination network structure (Theorem 6),
- a lower bound on the gap (Theorem 7).

Our new upper bound on $r_{\text{max}}$ is better than a previous bound from [17] (recalled in Corollary 9 for $h \geq 2\ell + \varepsilon$, and the lower bounds outperform previous ones for the whole parameter range of non-trivially solvable generalized combination networks, and they agree with our upper bound up to a small constant factor, for $h \leq 2\ell$ or $h \geq 2\ell, \alpha = 2$.

To the best of our knowledge, our upper and lower bounds on the gap are the first such bounds considering fixed network parameters. These bounds are valid for all generalized combination networks with $\varepsilon \neq 0$. The asymptotic behavior of the upper and lower bound shows that $\text{gap}_2(\mathcal{N}) = \Theta(\log(r))$.

C. Paper Organization

The rest of this paper is organized as follows. In Section II we present two new upper bounds on the maximum number of middle-layer nodes, and in Section III we give two new lower bounds on it. In Section IV we show the gap between the upper and lower bound shows that $\text{gap}_2(\mathcal{N}) = \Theta(\log(r))$. The main result is given in Corollary 1 and Corollary 2.

II. Upper Bounds on The Maximum Number of Middle Layer Nodes

In this section we fix the network parameters $\alpha, \ell, \varepsilon, h$ and we bound from above the number of nodes in the middle layer. The main result is given in Corollary 1 and Corollary 2.

We denote by $\mathcal{G}(n, k)$ the Grassmannian of dimension $k$, which is a set of all $k$-dimensional subspaces of $\mathbb{F}_q^n$. The cardinality of $\mathcal{G}(n, k)$ is the well-known $q$-binomial coefficient (a.k.a. the Gaussian coefficient):

$$|\mathcal{G}(n, k)| = \binom{n}{k}_q := \prod_{i=0}^{k-1} q^n - q^i = \prod_{i=0}^{k-1} q^{n-i} - 1.$$

A good approximation of the $q$-binomial coefficient can be found in [23] Lemma 4:

$$q^k < \left[ \frac{n}{k} \right]_q < \gamma \cdot q^{k(n-k)}, \quad (1)$$

where $\gamma \approx 3.48$.

Lemma 1. Let $\alpha \geq 2$, $h, \ell, t \geq 1, \varepsilon \geq 0$, $h - \varepsilon \geq 2\ell$, and let $T$ be a collection of subspaces of $\mathbb{F}_q^{(h-\varepsilon)t}$ such that

(i) each subspace has dimension at most $\ell t$; and

(ii) any subset of $\alpha$ subspaces spans $\mathbb{F}_q^{(h-\varepsilon)t}$.

Then we have $\alpha \ell \geq h - \varepsilon$ and

$$|T| \leq \left( \left\lfloor \frac{h - \varepsilon}{\ell} \right\rfloor - 2 \right) + \left( \alpha - \left\lfloor \frac{h - \varepsilon}{\ell} \right\rfloor + 1 \right) \left[ \frac{\ell t + 1}{1} \right]_q.$$

Proof. Take arbitrarily $\left\lfloor \frac{h - \varepsilon}{\ell} \right\rfloor - 2$ subspaces from $T$ and take arbitrarily a subspace $W$ of dimension $(h - \varepsilon)t - \ell t - 1$ which contains all these $\left\lfloor \frac{h - \varepsilon}{\ell} \right\rfloor - 2$ subspaces. Then for any subspace $T \in T$, there is a hyperplane of $\mathbb{F}_q^{(h-\varepsilon)t}$ containing both $W$ and $T$. Note that there are $\left[ \frac{\ell t + 1}{1} \right]_q$ hyperplanes containing $W$ and each of them contains at most $\alpha - 1$ subspaces from $T$. Thus

$$|T| \leq \left( \left\lfloor \frac{h - \varepsilon}{\ell} \right\rfloor - 2 \right) + \left[ \frac{\ell t + 1}{1} \right]_q \alpha - 1 - \left( \left\lfloor \frac{h - \varepsilon}{\ell} \right\rfloor - 2 \right)$$

$$= \left( \left\lfloor \frac{h - \varepsilon}{\ell} \right\rfloor - 2 \right) + \left( \alpha - \left\lfloor \frac{h - \varepsilon}{\ell} \right\rfloor + 1 \right) \left[ \frac{\ell t + 1}{1} \right]_q.$$

Theorem 1. Let $\alpha \geq 2$, $h, \ell, t \geq 1, \varepsilon \geq 0$, $h - \varepsilon \geq 2\ell$, and let $S$ be a collection of subspaces of $\mathbb{F}_q^{ht}$ such that

(i) each subspace has dimension at most $\ell t$; and

(ii) any subset of $\alpha$ subspaces spans a subspace of dimension at least $(h - \varepsilon)t$. 

Then we have $\alpha \ell \geq h - \varepsilon$ and
\[
|S| \leq \left( \left\lfloor \frac{(\varepsilon + \ell) t}{q} \right\rfloor \left( \alpha - \left\lfloor \frac{h - \varepsilon}{\ell} \right\rfloor + 1 \right) q^{\ell t + 1} - 1 + \left\lfloor \frac{h - \varepsilon}{\ell} \right\rfloor \right)
\]
\[
< \gamma \left( \alpha - \left\lfloor \frac{h - \varepsilon}{\ell} \right\rfloor + 1 \right) q^{\ell t (\varepsilon t + 1) + \left\lfloor \frac{h - \varepsilon}{\ell} \right\rfloor} - 1.
\]

**Proof:** Take arbitrarily $\left\lfloor \frac{h - \varepsilon}{\ell} \right\rfloor - 1$ subspaces from $S$ and a subspace $W \subseteq \mathbb{F}_q^{ht}$ of dimension $(h - \varepsilon)t - \ell t$ such that $W$ contains all these $\left\lfloor \frac{h - \varepsilon}{\ell} \right\rfloor - 1$ subspaces. Then for any subspace $S \in S$ there is a subspace of dimension $(h - \varepsilon)t$ containing both $W$ and $S$.

Let $m := \left\lfloor \frac{(\varepsilon + \ell) t}{q} \right\rfloor$. Then there are $m$ subspaces of dimension $(h - \varepsilon)t$ containing $S$, say $W_1, W_2, \ldots , W_m$. Note that every $\alpha$ subspaces in $W_i \cap S$ span the subspace $W_i$. According to Lemma 1, we have
\[
|W_i \cap S| \leq \left( \left\lfloor \frac{h - \varepsilon}{\ell} \right\rfloor - 2 \right) + \left( \alpha - \left\lfloor \frac{h - \varepsilon}{\ell} \right\rfloor + 1 \right) \left[ \ell t + 1 \right] q^\ell t - 1.
\]

Hence,
\[
|S| \leq \sum_{i=1}^{m} \left( |W_i \cap S| - \left( \left\lfloor \frac{h - \varepsilon}{\ell} \right\rfloor - 1 \right) - \left\lfloor \frac{h - \varepsilon}{\ell} \right\rfloor \right) q^{\ell t (\varepsilon t + 1) + \left\lfloor \frac{h - \varepsilon}{\ell} \right\rfloor} - 1.
\]

The inequality $(*)$ is derived by 1.

The following corollary rephrases Theorem 1 with network parameters.

**Corollary 1.** Let $\alpha \geq 2$, $h, \ell, t \geq 1$, $\varepsilon \geq 0$, and $h - \varepsilon \geq 2\ell$. If $(\varepsilon, \ell) - \mathcal{N}_{h, r, \alpha \ell + \varepsilon}$ has a $(q, t)$-linear solution then
\[
r \leq r_{\max} < \gamma q^{(\ell t + 1) (h - \varepsilon)} + \alpha - \theta,
\]
where $\theta := \alpha - \left\lfloor \frac{h - \varepsilon}{\ell} \right\rfloor + 1$ and $\gamma \approx 3.48$.

**Proof:** If a $(q, t)$-linear solution exists, then each of the $r$ nodes in the middle layer gets a subspace of dimension $\ell t$ of the source messages space. Since all receivers are able to recover the entire source message space, every $\alpha$-subset of the middle nodes span a subspace of dimension at least $(h - \varepsilon)t$. We then use Theorem 1.

Theorem 1 and Corollary 1 are valid for all $\alpha \geq 2$. However, we derive a better upper bound for $\alpha = 2$, as shown in the following theorem.

**Theorem 2.** Let $\alpha = 2$, $h, \ell, t \geq 1$, $\varepsilon \geq 0$, and let $S$ be a collection of subspaces of $\mathbb{F}_q^{ht}$ such that

(i) each subspace has dimension at most $\ell t$; and
(ii) the sum of any two subspaces has dimension at least $(h - \varepsilon)t$.

Then we have
\[
|S| \leq \left( \left\lfloor \frac{2(t - (h - \varepsilon)t + 1)}{2q^{\ell t}} \right\rfloor \right) q^{(h - \varepsilon)(2t + \varepsilon - h)t^2 + (h - \ell)t}.
\]

**Proof:** We may assume that each subspace has dimension $\ell t$. Since the sum of every two subspaces has dimension at least $(h - \varepsilon)t$, then their intersection has dimension at most $2\ell t - (h - \varepsilon)t$. It follows that any subspace of dimension $2\ell t - (h - \varepsilon)t + 1$ is contained in at most one subspace of $S$. Note that there are $\left[ \frac{2\ell t}{2q^{\ell t - (h - \varepsilon)t + 1}} \right]$ subspaces of dimension $2\ell t - (h - \varepsilon)t + 1$ and each subspace of dimension $\ell t$ contains $\left[ \frac{\ell t}{q^{\ell t - (h - \varepsilon)t + 1}} \right]$ such spaces. We have that
\[
|S| \leq \left( \left\lfloor \frac{2\ell t}{2q^{\ell t - (h - \varepsilon)t + 1}} \right\rfloor \right) q^{(h - \varepsilon)(2t + \varepsilon - h)t^2 + (h - \ell)t}.
\]

The following corollary rephrases Theorem 2 with network parameters.

**Corollary 2.** Let $\alpha = 2$, $h, \ell, t \geq 1$, $\varepsilon \geq 0$. If $(\varepsilon, \ell) - \mathcal{N}_{h, r, 2\ell t + \varepsilon}$ has a $(q, t)$-linear solution then
\[
r \leq r_{\max} < \gamma q^{(\ell t + 1) (h - \varepsilon)} + \alpha - \theta,
\]
where $\gamma \approx 3.48$.

**Proof:** If a $(q, t)$-linear solution exists, then each of the $r$ nodes in the middle layer gets a subspace of dimension $\ell t$ of the source messages space. Since all receivers are able to recover the entire source message space, any two subset of the middle nodes span a subspace of dimension at least $(h - \varepsilon)t$. We then use Theorem 2.
III. LOWER BOUNDS ON THE MAXIMUM NUMBER OF MIDDLE LAYER NODES

We now turn to study a lower bound on \( r_{\text{max}} \) with the parameters \( \alpha, \ell, \varepsilon, h \) being fixed. The main results are summarized in Theorem 5 and Corollary 5. In the following, we first give the condition on the coding coefficients under which a linear solution exists.

Let \( x_1, \ldots, x_h \in \mathbb{F}_q^s \) denote the \( h \) source messages and \( y_1, \ldots, y_N \in \mathbb{F}_q^{(\varepsilon+\alpha)ht} \) the messages received by each receiver.\(^1\) Since each middle-layer node receives \( \ell \) incoming edges, and has \( \ell \) outgoing edges directed at a given receiver, we may assume without loss of generality that this node just forwards its incoming messages. Let us denote the coding coefficients used by the source node for the messages transmitted directly to the receivers by \( A_1, \ldots, A_r \in \mathbb{F}_q^{\ell \times ht} \). Additionally, we denote the coding coefficients used by the source node for the messages transmitted directly to the receivers by \( B_1, \ldots, B_N \in \mathbb{F}_q^{\varepsilon \times ht} \).

Each receiver has to solve the following linear system of equations (LSE):

\[
y_i = \begin{pmatrix} A_{i_1} \\ \vdots \\ A_{i_{\alpha}} \end{pmatrix} (x_1, \ldots, x_h)^{(\varepsilon+\alpha)ht \times ht} = \begin{pmatrix} y_1 \\ \vdots \\ y_N \end{pmatrix}, \quad \forall i = 1, \ldots, N = \begin{pmatrix} r \end{pmatrix},
\]

where \( \{A_{i_1}, \ldots, A_{i_\alpha}\} \subset \{A_1, \ldots, A_r\} \).

Any receiver can recover the \( h \) source messages \( x_1, \ldots, x_h \) if and only if

\[
\text{rank} \begin{pmatrix} A_{i_1} \\ \vdots \\ A_{i_{\alpha}} \end{pmatrix}_{\alpha \ell \times ht} \geq (h - \varepsilon)\ell, \quad \forall i = 1, \ldots, N. \quad (2)
\]

Here the solution of the \( (\varepsilon, \ell) - N_{h,r,\alpha\ell + \varepsilon} \) network is a set of the coding coefficients \( \{A_1, \ldots, A_r\} \) s.t. (2) holds (where \( B_1, \ldots, B_N \) may be easily determined from the solution).

A. A Lower Bound by the Lovász-Local Lemma

**Lemma 2** (The Lovász-Local-Lemma [2, Ch. 5], [3]). Let \( \mathcal{E}_1, \mathcal{E}_2, \ldots, \mathcal{E}_k \) be a sequence of events. Each event occurs with probability at most \( p \) and each event is independent of all the other events except for at most \( d \) of them. If \( epd \leq 1 \), then there is a non-zero probability that none of the events occurs.

We choose the matrices \( A_1, \ldots, A_r \in \mathbb{F}_q^{\ell \times ht} \) independently and uniformly at random. For \( 1 \leq i_1 < \cdots < i_{\alpha} \leq r \), we define the event

\[
\mathcal{E}_{i_1, \ldots, i_{\alpha}} := \left\{ \begin{pmatrix} A_{i_1}, \ldots, A_{i_{\alpha}} \end{pmatrix} \mid \text{rank} \begin{pmatrix} A_{i_1} \\ \vdots \\ A_{i_{\alpha}} \end{pmatrix} < (h - \varepsilon)\ell \right\}.
\]

Let \( p = \Pr(\mathcal{E}_{i_1, \ldots, i_{\alpha}}) \) and denote by \( d \) the number of other events \( \mathcal{E}_{i'_1, \ldots, i'_{\alpha}} \) that are dependent on \( \mathcal{E}_{i_1, \ldots, i_{\alpha}} \).

**Lemma 3.** Let \( \alpha \geq 2, \ h, \ell, \varepsilon \geq 1, \ varepsilon > 0 \). Fixing \( 1 \leq i_1 < \cdots < i_{\alpha} \leq r \), we have

\[
\Pr(\mathcal{E}_{i_1, \ldots, i_{\alpha}}) \leq 2\gamma \cdot q^{(h - \alpha\ell - \varepsilon)\ell^2 + (h - \alpha\ell - 2\varepsilon)\ell - 1},
\]

where \( \gamma \approx 3.48 \).

**Proof:** The number of matrices \( A \in \mathbb{F}_q^{\ell \times n} \) of rank \( s \) is

\[
M(m, n, s) := \prod_{j=0}^{s-1} (q^n - q^j)(q^n - q^j) \leq \gamma \cdot q^{(m+n)s-s^2}. \quad (3)
\]

\(^1\)The vector \( y_i \) is the concatenation of all the messages received by the \( i \)th receiver node.
Then,
\[
\Pr(\mathcal{E}_{i_1, \ldots, i_n}) = \sum_{i=0}^{(h-\varepsilon)t-1} M(\alpha \ell t, ht, i) q^{\alpha th t^2} (h-\varepsilon)^{t-1} \sum_{i=0}^{(h-\varepsilon)t-1} \gamma \cdot q^{(h+\alpha \ell) t - i^2} \leq \frac{\gamma \cdot q^{(h+\alpha \ell) t - i^2} \cdot q^{\max_i ((h+\alpha \ell) t - i^2) - \alpha th t^2}}{q^{\alpha th t^2}} = \frac{\gamma \cdot q^{(h+\alpha \ell) t - i^2} \cdot q^{(h+\alpha \ell) t - i^2}}{q^{\alpha th t^2}} \leq \gamma \cdot 2^{q(h-\alpha \ell - \varepsilon) t^2 + (h-\alpha \ell - 2\varepsilon) t - 1} \quad (4)
\]
where (4) holds due to (3). (5) follows from a geometric sum, and (6) follows by maximizing \((h + \alpha \ell) t - i^2\).

**Lemma 4.** Let \(\alpha \geq 2\), \(h, \ell, t \geq 1\), \(\varepsilon \geq 0\). Fixing \(1 \leq i_1 < \cdots < i_\alpha \leq r\), the event \(\mathcal{E}_{i_1, \ldots, i_\alpha}\) is statistically independent of all the other events \(\mathcal{E}_{i'_1, \ldots, i'_\alpha}\) \((1 \leq i'_1 < \cdots < i'_\alpha \leq r)\), except for at most \(\alpha^{(r-1)}\) of them.

**Proof:** For \(1 \leq i_1 < \cdots < i_\alpha \leq r\) and \(1 \leq i'_1 < \cdots < i'_\alpha \leq r\), the events \(\mathcal{E}_{i_1, \ldots, i_\alpha}\) and \(\mathcal{E}_{i'_1, \ldots, i'_\alpha}\) are statistically independent if and only if \(\{i_1, \ldots, i_\alpha\} \cap \{i'_1, \ldots, i'_\alpha\} = \emptyset\). Thus, having chosen \(1 \leq i_1 < \cdots < i_\alpha \leq r\), there are at most \(\alpha^{(r-1)}\) ways of choosing an independent event.

**Remark 1.** Lemma 3 is a union-bound argument on the number of dependent events. The exact number is \(\binom{r}{\alpha} - \binom{r-\alpha}{\alpha}\). However the exact expression makes it harder to resolve everything for \(r\) later so we use the bound here.

**Theorem 3.** Let \(\alpha \geq 2\), \(\varepsilon \geq 0\), \(\ell, t \geq 1\), and \(1 \leq h \leq \alpha \ell + \varepsilon\) be fixed integers. If
\[
r \leq \beta \cdot q^{\frac{f(t)}{\alpha-1}} \quad (7)
\]
where \(\beta := \left(\frac{(\alpha-1)!}{2\varepsilon \gamma \alpha}\right)^{\frac{1}{\alpha-1}}\), \(\gamma \approx 3.48\) and \(f(t) := (\alpha \ell + \varepsilon - h) t^2 + (\alpha \ell + 2\varepsilon - h) t + 1\), then \((\varepsilon, \ell) - N_{h, r, \alpha \ell + \varepsilon}\) has a \((q, t)\)-linear solution.

Namely, for an \((\varepsilon, \ell) - N_{h, r, \alpha \ell + \varepsilon}\) that has a \((q, t)\)-linear solution, the maximum number of middle nodes satisfies
\[
r_{\max} \geq \beta \cdot q^{\frac{f(t)}{\alpha-1}}.
\]

**Proof:** By the Lovász Local Lemma, it suffices to show that \(\epsilon \cdot pd \leq 1\). Noting that \(d \leq \alpha^{(r-1)} \leq \alpha \cdot \frac{(r-1)^{\alpha-1}}{(\alpha-1)!}\), we shall require
\[
e \cdot 2 \gamma q^{(h-\alpha \ell - \varepsilon) t^2 + (h-\alpha \ell - 2\varepsilon) t - 1} \cdot \alpha \cdot \frac{(r-1)^{\alpha-1}}{(\alpha-1)!} \leq 1.
\]
Namely, if \(r \leq \beta \cdot q^{\frac{f(t)}{\alpha-1}}\), then \((\varepsilon, \ell) - N_{h, r, \alpha \ell + \varepsilon}\) has a \((q, t)\)-linear solution. We omit the plus one for simplicity.

**Remark 2.** For any \(\alpha \geq 7\), (7) can be simplified to
\[
r \leq q^{\frac{f(t)}{\alpha-1}},
\]
since the prefactor \(\beta > 1\) for all \(\alpha \geq 7\).

**Remark 3.** For \(t \geq 3\), \(\alpha \geq 5\) or \(q \geq 4\), it can be seen from numerical analysis that \(\beta \cdot q^{\frac{f(t)}{\alpha-1}} \geq 1\). Thus, (7) can be simplified to a looser upper bound
\[
r \leq q^{\frac{f(t)}{\alpha-1} - \varepsilon}. \quad
\]
However, omitting the term \(\beta \cdot q^{\frac{f(t)}{\alpha-1}}\) will cause a loss in estimating the maximum achievable number of middle nodes. Nevertheless, the loss is negligible when \(t \to \infty\).

**B. A Lower Bound by \(\alpha\)-Covering Grassmannian Codes**

**Definition 1** (Covering Grassmannian Codes [17]). An \(\alpha\)-(n, k, δ) covering Grassmannian code \(\mathbb{C}\) is a subset of \(\mathbb{G}(n, k)\) such that each subset with \(\alpha\) codewords of \(\mathbb{C}\) spans a subspace whose dimension is at least \(\delta + k\) in \(\mathbb{F}_q^n\).

The following theorem from [17] shows the connection between covering Grassmannian codes and linear network coding solutions.
Theorem 4 ([17] Thm. 4). The $(\varepsilon, \ell) - N_{h,r,\alpha t+\varepsilon}$ network is solvable with a $(q,t)$-linear solution if and only if there exists an $\alpha$-($ht, \ell t, h\ell \varepsilon - \ell t - \varepsilon t$) network with $r$ codewords.

Let $B_q(n, k; \delta; \alpha)$ denote the maximum possible size of an $\alpha$-($n, k, \delta$) covering Grassmannian code. Let $A$ be a $k \times (n-k)$ matrix, and let $I_k$ be a $k \times k$ identity matrix. The matrix $[I_k, A]$ can be viewed as a generator matrix of a $k$-dimensional subspace of $\mathbb{F}_q^n$, and it is called the lifting of $A$. When all the codewords of an MRD code are lifted to $k$-dimensional subspaces, the result is called lifted MRD code, denoted by $C^{\text{MRD}}$.

Theorem 5. Let $n, k, \delta$ and $\alpha$ be positive integers such that $1 \leq \delta \leq k$, $\delta + k \leq n$ and $\alpha \geq 2$. Then

$$B_q(n, k; \delta; \alpha) \geq (\alpha - 1)q^{\max\{n-k, \min\{k, n-k\}-\delta+1\}}.$$  

**Proof:** Let $m = n-k$ and $K = \max\{m, n-m\}(\min\{m, n-m\}-\delta+1)$. Since $\delta \leq \min\{m, n-m\}$, an $[m \times (n-m), K, \delta]_q$ MRD code $C$ exists. Let $C^{\text{MRD}}$ be the lifted code of $C$. Then $C^{\text{MRD}}$ is a subspace code of $\mathbb{F}_q^m$, which contains $qK$ $m$-dimensional subspaces as codewords and its minimum subspace distance is $2\delta$ [32].

Hence, for any two different codewords $C_1, C_2 \in C^{\text{MRD}}$ we have

$$\dim(C_1 \cap C_2) \leq m - \delta.$$  

Now, let $D = \{C \mid C \in C^{\text{MRD}}\}$. Take $\alpha - 1$ copies of $D$ and denote their multisets union as $D^{(\alpha)}$. We claim that $D^{(\alpha)}$ is an $\alpha$-($n, k, \delta$) covering Grassmannian code. For each codeword of $D^{(\alpha)}$, since it is the dual of a codeword in $C^{\text{MRD}}$, it has dimension $n-m$, which is $k$. For arbitrarily $\alpha$ codewords $D_1, D_2, \ldots, D_\alpha$ of $D^{(\alpha)}$, there exist $1 \leq i < j \leq \alpha$ such that $D_i \neq D_j$. Let $C_i = D_i^\perp$ and $C_j = D_j^\perp$. Then $C_i$ and $C_j$ are two distinct codewords of $C^{\text{MRD}}$. It follows that

$$\dim\left(\bigoplus_{\ell=1}^{\alpha} D_\ell\right) \geq \dim(D_i + D_j) - n - \dim(D_i^\perp \cap D_j^\perp) = n - \dim(C_i \cap C_j) \geq n - m + \delta = k + \delta.$$  

So far we have shown that $D^{(\alpha)}$ is an $\alpha$-($n, k, \delta$) covering Grassmannian code. Then the conclusion follows by noting that

$$\|D^{(\alpha)}\| = (\alpha - 1)\|D\| = (\alpha - 1)\|C^{\text{MRD}}\| = (\alpha - 1)q^{\max\{n-k, \min\{k, n-k\}-\delta+1\}}.$$  

Corollary 3 below results from the relation between covering Grassmannian codes and network solutions in Theorem 4 and the lower bound on the cardinality of covering Grassmannian codes in Theorem 5.

**Corollary 3.** Let $\alpha \geq 2$, $h, \ell, t \geq 1$, $\varepsilon \geq 0$, $h \leq 2\ell + \varepsilon$. For an $(\varepsilon, \ell) - N_{h,r,\alpha t+\varepsilon}$ which has a $(q,t)$-linear solution, the maximum number of middle nodes

$$r_{\text{max}} \geq (\alpha - 1)q^{\gamma(t)}$$  

where

$$g(t) := \max\{\ell t, (h - \ell) t\} \cdot \min\{\ell t, (h - \ell) t\} - (h - \ell - \varepsilon)t + 1$$

$$= \begin{cases} (\ell t^2 + \ell t) & h \leq 2\ell, \\ (h - \ell)(2\ell + \varepsilon - h)t^2 + (h - \ell)t & \text{otherwise.} \end{cases}$$

IV. BOUNDS ON THE FIELD SIZE GAP

In previous sections, we discussed bounds on $r_{\text{max}}$. The main results in this section are the lower and upper bounds on $\text{gap}_2(N)$ in Theorem 7 and 6 respectively. To discuss $\text{gap}_2(N)$, we first need the following conditions on the smallest field size $q_v(N)$ or $q_v(N)$, for which a network $N$ is solvable.

**Lemma 5.** Let $\alpha \geq 2$, $r, h, \ell, t \geq 1$, $\varepsilon \geq 0$. If $(\varepsilon, \ell) - N_{h,r,\alpha t+\varepsilon}$ has a $(q,t)$-linear solution then

$$q^t \geq \begin{cases} \left(\frac{r + \theta - \alpha}{\gamma - \theta}\right)^{\frac{r}{\gamma}} & h \geq 2\ell + \varepsilon, \\ \left(\frac{r}{\gamma(\alpha - 1)}\right)^{\frac{r}{\gamma}} & \text{otherwise,} \end{cases}$$

where $\theta := \alpha - \lceil\frac{h - \varepsilon}{\ell}\rceil + 1$ and $\gamma \approx 3.48$.

**Proof:** The first case follows from Corollary 1 that for $h \geq 2\ell + \varepsilon$, $q^t \geq \left(\frac{r + \theta - \alpha}{\gamma - \theta}\right)^{\frac{r}{\gamma}}$. The second case is derived from an upper bound on $r$ in [17] (recalled in Corollary 6) in a similar manner. \hfill \blacksquare
Lemma 6. Let $\alpha \geq 2$, $r, h, t \geq 1$, $\epsilon \geq 0$. There exists a $(q, t)$-linear solution to $(\epsilon, \ell) - \mathcal{N}_{h, r, \alpha \ell + \epsilon}$ when

$$ q^t \geq \begin{cases} \left( \frac{r}{1} \right)^{\frac{\alpha - 1 + 1}{\alpha - 1}} h \geq 2\ell + \epsilon & \\
\left( \frac{r}{\alpha - 1} \right)^{\frac{\alpha - 1}{\alpha - 1}} & \text{otherwise}, \end{cases} $$

where $\beta$ and $f(t)$ are defined as in Theorem 3 and $g(t)$ is defined as in Corollary 3.

Proof: The proof is similar to that in Lemma 5 and the cases follow from Theorem 3 and Corollary 3 respectively. ■

Lemma 5 and Lemma 6 can be seen as the necessary and the sufficient conditions respectively on the pair $(q, t)$ s.t. a $(q, t)$-linear solution exists.

In the following, we use the lemmas above to derive bounds on the gap$_2(\mathcal{N})$ for a given network $\mathcal{N}$. The bounds are determined only by the network parameters.

Theorem 6. Let $\alpha \geq 2$, $r, h, \ell \geq 1$, $\epsilon \geq 0$. Then for the $(\epsilon, \ell) - \mathcal{N}_{h, r, \alpha \ell + \epsilon}$ network,

$$ \text{gap}_2(\mathcal{N}) \leq \frac{\alpha - 1}{\theta(1)} \log_2 \left( \frac{r}{\alpha - 1} \right) - A h \geq 2\ell + \epsilon $$

where $\theta := \alpha - \left[ \frac{h - \epsilon}{t} \right] + 1$, $\beta$ and $f(t)$ are defined as in Theorem 3 and $g(t)$ is defined as in Corollary 3 and we define $A := \min \left\{ \log_2(q^t) \left| q^t \geq \frac{r + \theta - \alpha}{\gamma \theta} f(t) \right. \right\}$ and $B := \min \left\{ \log_2(q^t) \left| q^t \geq \frac{r + \theta - \alpha}{\gamma \theta} g(t) \right. \right\}$.

Furthermore, for $t_A := \min \left\{ t \left| 2^t \geq \frac{r + \theta - \alpha}{\gamma \theta} f(t) \right. \right\} > 2$, we have

$$ A \geq \min \left\{ t_A, \frac{1}{\ell \left( \epsilon (t_A - 2) + 1 \right)} \log_2 \left( \frac{r + \theta - \alpha}{\gamma \theta} f(t) \right) \right\} \geq t_A - 1, $$

and for $t_B := \min \left\{ t \left| 2^t \geq \frac{r + \theta - \alpha}{\gamma \theta} g(t) \right. \right\} > 2$, we have

$$ B \geq \min \left\{ t_B, \frac{1}{\ell \left( \epsilon (t_B - 2) + 1 \right)} \log_2 \left( \frac{r + \theta - \alpha}{\gamma \theta} g(t) \right) \right\} \geq t_B - 1. $$

Proof: We only prove the bound for the case $h \geq 2\ell + \epsilon$. The other case follows analogously. Lemma 5 implies that $q_0(\mathcal{N}) \leq \left( \frac{r}{\beta} \right)^{\frac{1}{\gamma \theta}}$. By the definition of $q_0(\mathcal{N})$ and Lemma 5, $q^t = q_0(\mathcal{N})$ must fulfill

$$ q^t \geq \left( \frac{r + \theta - \alpha}{\gamma \theta} \right)^{\frac{1}{\gamma \theta (t + 1)}}. $$

Hence, we get a lower bound on $q_0(\mathcal{N})$ by determining the smallest $q^t$ that fulfills this inequality, i.e., $A$. Note that the left-hand side of the inequality is a strictly monotonically increasing function in $t$ (for a fixed $q$), and the right side is monotonically decreasing in $t$ (among others, this implies that $A$ and $t_A$ are well-defined).

For the lower bound on $A$ for $t_A > 2$, consider the case that there is a prime power $q > 2$ and a positive integer $t$ with

$$ 2^{t_A} \geq q^t \geq \left( \frac{r + \theta - \alpha}{\gamma \theta} \right)^{\frac{1}{\gamma \theta (t + 1)}}. $$

Then we have $t \leq t_A - 2$ since $q \geq 3$ and $t_A \geq 3$. Hence,

$$ q^t \geq \left( \frac{r + \theta - \alpha}{\gamma \theta} \right)^{\frac{1}{\gamma \theta (t_A - 1) + 1}} \geq \left( \frac{r + \theta - \alpha}{\gamma \theta} \right)^{\frac{1}{\gamma \theta (t_A - 1) + 1}} \geq 2^{t_A - 1}, $$

which proves the claim. ■

Corollary 4. Let $\alpha \geq 2$, $r, h, \ell \geq 1$, $\epsilon \geq 0$. Then for the $(\epsilon, \ell) - \mathcal{N}_{h, r, \alpha \ell + \epsilon}$ network,

$$ \text{gap}_2(\mathcal{N}) \leq \frac{\alpha - 1}{\theta(1)} \log_2 \left( \frac{r}{\alpha - 1} \right) - \max \left\{ \frac{1}{\ell \left( \epsilon (t_A - 2) + 1 \right)} \log_2 \left( \frac{r + \theta - \alpha}{\gamma \theta} \right) + \frac{1}{4\epsilon} - \frac{2 \epsilon + 1}{2 \epsilon}, 1 \right\} h \geq 2\ell + \epsilon $$

In particular, if all parameters are constants except for $r \to \infty$, then $\text{gap}_2(\mathcal{N}) \in O(\log r)$.
Proof: We only prove the bound for the case \( h \geq 2 \ell + \varepsilon \). The other case follows analogously. We determine \( t_A \) as defined in Theorem 6. Note that \( 2^t \) is strictly monotonically increasing in \( t \) and \( \left( \frac{r + \theta - \alpha}{\gamma \theta} \right)^{\frac{1}{\ell (t + 1)}} \) is strictly monotonically decreasing. Hence, we have \( t_A = \lceil t' \rceil \), where \( t' \) is the unique (positive) solution of
\[
2^{t'} = \left( \frac{r + \theta - \alpha}{\gamma \theta} \right)^{\frac{1}{\ell (t' + 1)}}.
\]
By rewriting this equation into a quadratic equation in \( t' \), we obtain the following positive solution:
\[
t' = \frac{1}{\ell \varepsilon} \log_2 \left( \frac{r + \theta - \alpha}{\gamma \theta} \right) + \frac{1}{4 \varepsilon^2} - \frac{1}{2 \epsilon}.
\]
Using the bound \( A \geq t_A - 1 \) for \( t_A \geq 2 \) (Theorem 6) and the trivial bound \( A \geq 1 \) otherwise, the claim follows. The asymptotic statement is an immediate consequence.

**Theorem 7.** Let \( \alpha \geq 2 \), \( r, h, \ell \geq 1 \), \( \varepsilon \geq 0 \). Then for the \( (\varepsilon, \ell) - \mathcal{N}_{h, r, \alpha \ell + \varepsilon} \) network,
\[
\text{gap}_2(\mathcal{N}) \geq \begin{cases} 
\frac{1}{\ell (\varepsilon + 1)} \log_2 \left( \frac{r + \theta - \alpha}{\gamma \theta} \right) - t_\Delta & h \geq 2 \ell + \varepsilon \\
\frac{1}{\ell (\varepsilon + 1)} \log_2 \left( \frac{r + \theta - \alpha}{\gamma \theta} \right) - t_* & \text{otherwise},
\end{cases}
\]
where \( t_\Delta \) is the smallest positive integer s.t. \( 2^{\frac{\log_2 (r + \theta - \alpha)}{\ell (\varepsilon + 1)}} \geq \frac{r}{\beta} \) and \( t_* \) is the smallest positive integer s.t. \( 2^{\log_2 (r + \theta - \alpha)} \geq \frac{r}{\alpha - 1} \). Here, \( \beta \) and \( f(t) \) are defined as in Theorem 3 and \( g(t) \) is defined as in Corollary 3.

Proof: Let us only consider the first case \( h \geq 2 \ell + \varepsilon \). The other case can be proved in the same manner. According to Lemma 5, we have the lower bound on the smallest field size of a scalar solution,
\[
q_\nu(\mathcal{N}) \geq \left( \frac{r + \theta - \alpha}{\gamma \cdot \theta} \right)^{\frac{1}{\ell (\varepsilon + 1)}}.
\]
For vector solutions, according to Lemma 6, we want to find \((q, t) \) s.t. \( q^{\frac{\log_2 (r + \theta - \alpha)}{\ell (\varepsilon + 1)}} \geq \frac{r}{\beta} \). Since \( t_\Delta \) is the smallest positive integer \( t \) s.t. \( 2^{\frac{\log_2 (r + \theta - \alpha)}{\ell (\varepsilon + 1)}} \geq \frac{r}{\beta} \), it is guaranteed that a \((2, t_\Delta)\)-linear solution exists. Therefore, \( q_\nu(\mathcal{N}) \) (the smallest value of \( q^t \)) should be at most \( q_\nu(\mathcal{N}) \leq 2^{t_\Delta} \). The lower bound then follows directly from the definition of \( \text{gap}_2(\mathcal{N}) \).

By carefully bounding \( t_* \) and \( t_\Delta \), the following is obtained:

**Corollary 5.** Let \( \alpha \geq 2 \), \( r, h, \ell, \varepsilon \geq 1 \). Then for the \( (\varepsilon, \ell) - \mathcal{N}_{h, r, \alpha \ell + \varepsilon} \) network,
\[
\text{gap}_2(\mathcal{N}) \geq \begin{cases} 
\frac{\log_2 (r + \theta - \alpha)}{\ell (\varepsilon + 1)} - \frac{(\alpha - 1) \log_2 \left( \frac{r \gamma}{\beta} \right)}{(\alpha \ell + \varepsilon - h) \varepsilon} & h \geq 2 \ell + \varepsilon, \\
\frac{\log_2 (r + \theta - \alpha)}{\ell (\varepsilon + 1)} - \frac{(\alpha - 1) \log_2 \left( \frac{r \gamma}{\beta} \right)}{(\alpha \ell + \varepsilon - h) \varepsilon} & \text{otherwise},
\end{cases}
\]
In particular, if all parameters are constants except for \( r \to \infty \), then \( \text{gap}_2(\mathcal{N}) \in \Omega(\log r) \).

Proof: When \( h \geq 2 \ell + \varepsilon \), noting that \( \alpha \ell + 2 \varepsilon - h > 0 \), we may choose
\[
t = \left( \frac{(\alpha - 1) \log_2 \left( \frac{r \gamma}{\beta} \right)}{\alpha \ell + \varepsilon - h} \right)^{1/2}
\]
such that \( 2^{f(t)} \geq 2^{(\alpha \ell + \varepsilon - h) \varepsilon^2} = \left( \frac{r \gamma}{\beta} \right)^{\alpha - 1} \). Then we have that
\[
\text{gap}_2(\mathcal{N}) \geq \frac{\log_2 (r + \theta - \alpha)}{\ell (\varepsilon + 1)} - \left( \frac{(\alpha - 1) \log_2 \left( \frac{r \gamma}{\beta} \right)}{(\alpha \ell + \varepsilon - h) \varepsilon} \right)^{1/2}
\]
\[
\geq \frac{\log_2 (r + \theta - \alpha) - \log_2 \theta - 2}{\ell (\varepsilon + 1)} - \left( \frac{\log_2 r - \log_2 \beta}{(\ell - \frac{h - t - \varepsilon}{\alpha - 1}) \varepsilon} \right)^{1/2}
\]
Recall that \( \beta \) and \( \theta \) are determined by \( \alpha, h, \varepsilon, \) and \( \ell \). Thus if \( \alpha, h, \varepsilon, \) and \( \ell \) are fixed, \( \text{gap}_2(\mathcal{N}) = \Omega(\log r) \).

When \( h < 2 \ell + \varepsilon \), we may choose
\[
t = \left( \frac{\log_2 \left( \frac{r \gamma}{\beta} \right)}{\ell \varepsilon} \right)^{1/2}
\]
such that \( 2^{g(t)} \geq 2^{2\ell t^2} = \frac{r}{\alpha - 1} \). It follows that
\[
gap_2(N) \geq \frac{\log_2 \left( \frac{r}{\gamma (\alpha - 1)} \right)}{\ell (\varepsilon + 1)} - \frac{\log_2 \left( \frac{r}{\alpha - 1} \right)}{\ell \varepsilon} \frac{1}{2}
\geq \frac{\log_2 \left( \frac{r}{\alpha - 1} \right) - 2}{\ell (\varepsilon + 1)} - \frac{\log_2 \left( \frac{r}{\alpha - 1} \right)}{\ell \varepsilon} \frac{1}{2}
\]
This shows that \( \gap_2(N) \in \Omega(\log r) \).

Corollaries \( \text{[17, Corollary 3]} \) and \( \text{[5]} \) show that for fixed network parameters except for \( r \), the gap size grows as
\[
\gap_2(N) = \Theta(\log r) \quad (r \to \infty).
\]

**Example 8.** We illustrate the proof of Theorem \( \text{[6]} \) and Theorem \( \text{[7]} \) by two network examples with \( r = 8 \times 10^5 \) in Figure \( \text{[2]} \) and \( r = 8 \times 10^6 \) in Figure \( \text{[3]} \). Note that the curves in the figures are not bounds on the gap size. They are the necessary (blue curve) and the sufficient (green curve) condition on \( q^t \) such that a \((q,t)\)-linear solution exists. Namely, there is no \((q,t)\)-linear solution in the region below the blue curve and there must be a \((q,t)\)-linear solution in the region above the green curve. Thus the minimum gap of the network \((2,1) - N_{12, r, 20}\) is determined by the difference between the necessary condition with \( t = 1 \) and the minimum \( 2^t \) that is in the region above the sufficient condition. Similarly, the maximum gap of the network is determined by the difference between the sufficient condition with \( t = 1 \) and the minimum \( 2^t \) that is in the region above the necessary condition.

By comparing the two plots it can be seen that the gap increases as the number of middle node in the network increases.

\[ h = 12, \varepsilon = 2, \ell = 1, r = 800000, \alpha = 20 \]
\[ h = 12, \varepsilon = 2, \ell = 1, r = 8000000, \alpha = 20 \]

**Figure 2.** An illustration of proofs of Theorem \( \text{[6]} \) and Theorem \( \text{[7]} \) for the network \((2,1) - N_{12,8,5,20}\).

**Figure 3.** An illustration of proofs of Theorem \( \text{[6]} \) and Theorem \( \text{[7]} \) for the network \((2,1) - N_{12,8,6,20}\).

**V. Discussion**

In this section we will compare our upper and lower bound on \( r_{\text{max}} \) with previous known bounds.

**A. Other Upper Bound on \( r_{\text{max}} \)**

In the following we recall the result from \( \text{[17, Corollary 3]} \) and compare it with our upper bound in Corollary \( \text{[2]} \).

**Theorem 9 ( \( \text{[17, Corollary 3]} \)).** If \( n, k, \delta, \text{and} \alpha \) are positive integers such that \( 1 < k < n, 1 \leq \delta \leq n - k \) and \( 2 \leq \alpha \leq [\frac{k + \delta - 1}{k}] + 1 \), then for an \( \alpha - (n,k,\delta)^c \) covering Grassmannian code \( C \), we have that
\[
|C| \leq \left( \alpha - 1 \right)[\frac{n}{\alpha - 1}]_q - \left[ \frac{n}{\alpha - 1} \right]_q.
\]
By combining Theorem 9 and Theorem 4, the following corollary can be directly derived.

**Corollary 6.** If the \((\varepsilon, \ell) - N_{h, r, \alpha t + \varepsilon}\) network has a \((q, t)\)-linear solution then

\[
\begin{aligned}
r \leq r_{\text{max}} & \leq \left(\alpha - 1\right) \frac{\binom{ht-ct-1}{q}^{ht-ct-1}}{\binom{ht-ct}{q}^{ht-ct-1}} \\
& < \left(\alpha - 1\right) \frac{\gamma q^{(\varepsilon+1)(ht-ct-1)}}{q^{(\varepsilon+1)(ht-ct-1)}} \\
& = \gamma (\alpha - 1) q^{\ell t + 1},
\end{aligned}
\]

with \(1 < \ell t < ht\), \(0 \leq \varepsilon \leq h - \ell - \frac{1}{2}\), \(2 \leq \alpha \leq \left\lceil \frac{ht+ct-1}{\ell t} \right\rceil + 1\).

**B. Comparison Between Upper Bounds**

In the following, we first show that for some parameters, the upper bound in Corollary 1 could be better than that in Corollary 6. Denote

\[
\theta := \left(\alpha - \left\lceil \frac{h - \varepsilon}{\ell} \right\rceil + 1\right).
\]

The upper bound in Corollary 1 and Corollary 6 can be respectively written as

\[
U_A := \left(\varepsilon + \ell t\right) \binom{ht-ct-1}{q}^{ht-ct-1} \frac{\theta \cdot q^{\ell t + 1} - 1}{q - 1} + \alpha - \theta
\]

and

\[
U_B := (\alpha - 1) \frac{\binom{ht-ct-1}{q}^{ht-ct-1}}{\binom{ht-ct}{q}^{ht-ct-1}} = (\alpha - 1) q^{\ell t + 1} \prod_{i=0}^{\ell t} \frac{q^{ht-i-1} - 1}{q^{ht-i} - q^{\ell t}}.
\]

**Lemma 7.** Let \(h \geq 2\ell + \varepsilon\) and \(2 \leq \alpha \leq \left\lceil \frac{ht+ct-1}{\ell t} \right\rceil + 1\). Assume \(\left\lceil \frac{\varepsilon + \ell t}{\ell t} \right\rceil q \leq \alpha\), then

\[
\log_q U_A - \log_q U_B < \log_q \frac{2\alpha}{\alpha - 1} - \ell \varepsilon t^2.
\]

**Particularly, if**

\[
\frac{2\theta \alpha}{\alpha - 1} \leq q^{\varepsilon t^2},
\]

**then**

\[
U_A < U_B.
\]

*That is, the upper bound in Corollary 1 is better than that in Corollary 6.*

**Proof:** Under the assumption \(\left\lceil \frac{\varepsilon + \ell t}{\ell t} \right\rceil q \leq \alpha\), we have

\[
\begin{aligned}
\log_q U_A & \leq \log_q \left(\alpha \left(\theta \cdot \frac{q^{\ell t + 1} - 1}{q - 1} - 1\right) + \alpha - \theta\right) \\
& = \log_q \left(\alpha \theta \cdot \frac{q^{\ell t + 1} - 1}{q - 1} - \alpha + \alpha - \theta\right) \\
& = \log_q \left(\alpha + \log_q (\alpha \cdot \frac{q^{\ell t + 1} - 1}{q - 1} - 1)\right) \\
& < \log_q \left(\alpha + \log_q (\alpha \cdot \frac{q^{\ell t + 1} - 1}{q - 1})\right) \\
& \left(\ast\right) < \log_q \theta + \log_q \alpha + \log_q (2 \cdot q^{\ell t}) \\
& = \log_q \theta + \log_q \alpha + \ell t + \log_q 2.
\end{aligned}
\]

The inequality \((\ast)\) is because \(\frac{2^{\ell t + 1} - 1}{q - 1} = \sum_{i=0}^{\ell t} q^i < 2 \cdot q^{\ell t}\). By the bounds on the \(q\)-binomial coefficient,

\[
\log_q U_B > \log (\alpha - 1) + \ell t (\varepsilon t + 1),
\]
we have that
\[
\log_q U_A - \log_q U_B < \log_q \frac{2q\alpha}{\alpha - 1} - \ell \xi t^2.
\]
Together with the assumption \( \frac{2q\alpha}{\alpha - 1} \leq q^{\ell t^2} \), the conclusion follows.

**Lemma 8.** Let \( h \geq 2\ell + \varepsilon \) and \( 2 \leq \alpha \leq \lfloor \frac{h - \varepsilon - 1}{\ell t} \rfloor + 1 \). Assume \( \lfloor \frac{\varepsilon + \ell t}{\ell t} \rfloor \) \( \geq \alpha \). If \( h \geq 2\varepsilon \), then
\[
\frac{U_A}{U_B} \leq \frac{8\theta}{\alpha - 1}.
\]
So, when
\[
8\theta < \alpha - 1,
\]
we have that
\[
U_A < U_B.
\]
That is, the upper bound in Corollary \( \boxed{7} \) is better than that in Corollary \( \boxed{6} \).

**Proof:** Since \( \lfloor \frac{\varepsilon + \ell t}{\ell t} \rfloor \geq \alpha \), we have that
\[
U_A \leq \theta \cdot \left( \frac{(\varepsilon + \ell t)}{\ell t} \right)_q^{\frac{\ell t + 1}{2}} - 1.
\]
Then
\[
\frac{U_A}{U_B} \leq \frac{\theta}{\alpha - 1} \cdot \frac{q^{\ell t + 1}}{q - 1} \left( \frac{h - \ell}{\ell t} \right)_q \left( \frac{(h - \ell - \varepsilon t) - 1}{q} \right)_q \left( \frac{h - \ell - \varepsilon t}{q} \right)_q^{-1} \left( \frac{h - \ell - \varepsilon t}{q} \right)_q^{-1}
\]
\[
= \frac{\theta}{\alpha - 1} \cdot \frac{q^{\ell t + 1}}{q - 1} \left( \frac{q^{\ell t} \ldots q^{\ell t+1}}{q} \right) \left( \frac{q^{\ell t} \ldots q^{\ell t+1}}{q} \right) \left( \frac{q^{h\ell} \ldots q^{(h - \ell - \varepsilon t)} - 1}{q} \right) \left( \frac{q^{h\ell} \ldots q^{(h - \ell - \varepsilon t)} - 1}{q} \right)
\]
\[
< \frac{\theta}{\alpha - 1} \cdot \frac{q^{\ell t + 1}}{q - 1} \left( \frac{1 - 1}{q^t} \right)^{\ell t} \left( \frac{1 - 1}{q^t} \right)^{-1} \left( \frac{1 - 1}{q^t} \right)^{-1} \left( \frac{1 - 1}{q^t} \right)^{\ell t} \left( \frac{1 - 1}{q^t} \right)^{-1} \left( \frac{1 - 1}{q^t} \right)^{-1}
\]
\[
\leq \frac{\theta}{\alpha - 1} \cdot \left( 1 + \frac{1}{q - 1} \right) \left( 1 - \frac{1}{q^t} \right)^{\ell t} \left( 1 - \frac{1}{q^t} \right)^{-1} \left( \text{assume } 2\varepsilon \leq h \right)
\]
\[
< \frac{8 \cdot \theta}{\alpha - 1},
\]
and the conclusion follows.

Now, we compare the upper bound in Corollary \( \boxed{6} \) with that in Corollary \( \boxed{5} \) for \( \alpha = 2 \).

**Lemma 9.** Denote \( U_C := \gamma q^{(h - \ell)(2\ell + \varepsilon - h)\ell^2 + (h - \ell)\ell} \) and \( U_D := \gamma q^{(\ell t + \ell)}. \) Then
\[
\log_q U_C - \log_q U_D = [(h - \ell)(2\ell + \varepsilon - h) - \varepsilon \ell t^2 + (h - 2\ell)\ell t].
\]
Particularly, if one of the following three conditions is satisfied,
- \( \ell t + 1 < \ell t \), and either \( h > 2\ell \) or \( h < \ell + \varepsilon + \frac{1}{2} \);
- \( \ell t + 1 > \ell t \), and either \( h > \ell + \varepsilon + \frac{1}{2} \) or \( h < 2\ell \);
- \( \ell t + 1 = \ell t \) and \( h \neq 2\ell \),
then
\[
\log_q U_C - \log_q U_D < 0,
\]
and the upper bound in Corollary \( \boxed{2} \) is better than the upper bound in Corollary \( \boxed{6} \) for \( \alpha = 2 \).

**Proof:** Denote \( C = (h - \ell)(2\ell + \varepsilon - h)t + (h - \varepsilon) \) and \( D = \ell(t + 1) \). Then \( \log_q U_C - \log_q U_D = Ct - Dt \). So it suffices to show that \( C < D \). Note that \( C = -\ell h^2 + 3\ell h + \varepsilon \ell t + h + \cdots \) is a quadratic function in \( h \) which is symmetric about \( h = \frac{(2\ell + \varepsilon - h)}{2\ell} \). We proceed in three cases, according to the position of the axis of symmetry.
1) If \( t + 1 < \ell \), then \((\ell+\varepsilon)t+1 < 2\ell\), i.e., the axis of symmetry is on the left of \( h = 2\ell \). In this case, \( C \) is decreasing when \( h > 2\ell \). It follows that \( C < D \) for \( h > 2\ell \) as \( C = D \) when \( h = 2\ell \). Furthermore, according to the symmetry, \( C < D \) also holds for \( h < \ell + \varepsilon + \frac{1}{\varepsilon} \).

2) If \( t + 1 > \ell \), then \((\ell+\varepsilon)t+1 > 2\ell\). Using the same argument, we can see that \( C < D \) holds for \( h < 2\ell \) and \( h > \ell + \varepsilon + \frac{1}{\varepsilon} \).

3) If \( t + 1 = \ell \), then \((\ell+\varepsilon)t+1 = 2\ell\). The maximal value of \( C - D \) is taken at \( h = 2\ell \), which is 0. So \( C < D \) for all \( h \neq 2\ell \).

The following example shows that, in some cases, the upper bound in Corollary 3 matches a lower bound from [14] within a factor of \( \gamma \approx 3.48 \).

**Example 10.** Let \( \alpha = 2 \), \( \varepsilon = \ell \), and \( h = 2\ell + 1 \). A lower bound from [14] is

\[
q^{(\ell^2-1)t^2+((\ell+1)t)t} \leq r.
\]

For the upper bound, Corollary 2 shows that

\[
r \leq \gamma q^{(\ell^2-1)t^2+((\ell+1)t)t},
\]

agreeing with the lower bound up to a factor of \( \gamma \). In contrast, Corollary 6 shows that

\[
r \leq \gamma q^{\ell^2t^2+\ell t},
\]

which differs from the lower bound by a factor of \( \gamma q^{2^t} \).

**Corollary 7.** If \( n, k, \delta \), and \( \alpha \), are positive integers such that \( 1 < k < n \), \( 1 \leq \delta \leq \min\{n-k,k\} \), and \( 2 \leq \alpha \leq \begin{bmatrix} k+\delta-1 \end{bmatrix}q+1 \), then an upper bound on the size of an \( \alpha-(n,k,\delta) \) code \( C \) is that

\[
|C| \leq \left[\frac{n-\delta}{k}\right]q\left(\alpha - \left[\frac{\delta-k}{k}\right]+1\right)\frac{q^{k+1}-1}{q-1} - \left[\frac{\delta-k}{k}\right] - 1.
\]

**Proof:** Note that an \( \alpha-(n,k,\delta) \) code \( C \) exists if and only if the \( (\varepsilon,\ell) - \mathcal{N}_{h,r,\alpha t+\varepsilon} \) network is solvable with linear scalar solutions, where \( h = n \), \( r = |C| \), \( \ell = k \) and \( \varepsilon = h - \ell - \delta = n - k - \delta \). Then the conclusion follows from Corollary 6 by setting \( t = 1 \).

C. Other Lower Bounds on \( r_{\max} \)

Let \( B_q(n,k,\delta;\alpha) \) denote the maximum possible size of an \( \alpha-(n,k,\delta) \) covering Grassmannian code. Etzion et al. proposed the following lower bounds on \( B_q(n,k,\delta;\alpha) \) for \( \delta \leq k \) in [14].

**Theorem 11 ([14], Theorem 21).** Let \( 1 \leq \delta \leq k \), \( k + \delta \leq n \) and \( 2 \leq \alpha \leq q^k + 1 \) be integers.

1) If \( n < k + 2\delta \), then

\[
B_q(n,k,\delta;\alpha) \geq (\alpha - 1)q^{\max\{k-n,k-n\}(\min\{k-n,k-\delta\})+1}.
\]

2) If \( n \geq k + 2\delta \), then for each \( t \) such that \( \delta \leq t \leq n - k - \delta \), we have

a) If \( t < k \), then

\[
B_q(n,k,\delta;\alpha) \geq (\alpha - 1)q^{k(t-\delta+1)}B_q(n-t,k,\delta;\alpha).
\]

b) If \( t \geq k \), then

\[
B_q(n,k,\delta;\alpha) \geq (\alpha - 1)q^{k(t-\delta+1)}B_q(n-t,k,\delta;\alpha) + B_q(t+k-\delta,k,\delta;\alpha).
\]

Theorem 5 improves the theorem above by removing the conditions \( \alpha \leq q^k + 1 \) and \( n < k + 2\delta \). For \( n \geq k + 2\delta \), the numerical results show that either could be better, depending on the parameters. The theoretical comparison between the two lower bounds is hard due to the recursive function and is left for future research.

D. Discussion of Lower Bounds

In the following, we compare the lower bound on \( r_{\max} \) in Corollary 3 with the upper bounds in the previous sections.

- When \( h \leq 2\ell \), Corollary 3 gives

\[
r_{\max} \geq (\alpha - 1)q^{\ell t(\varepsilon+1)},
\]

which is close (up to a constant factor of \( \gamma \approx 3.48 \)) to the upper bound in Corollary 6 i.e.,

\[
r_{\max} \leq \gamma(\alpha - 1)q^{(\ell+1)t+1}.
\]
• When $h \geq 2\ell$ and $\alpha = 2$, Corollary [5] gives

$$r_{\text{max}} \geq q^{(h-\ell)(2h+\varepsilon-h)t^2+(h-\ell)t},$$

which is close (up to a constant factor of $\gamma$) to the upper bound in Theorem [2]

$$r_{\text{max}} < \gamma q^{(h-\ell)(2h+\varepsilon-h)t^2+(h-\ell)t}.$$

• The upper bound in Corollary [1] cannot be applied here as $(h-\varepsilon)/\ell \leq 2$.

VI. Conclusion

In this work, we studied necessary and sufficient conditions for the existence of $(q,t)$-linear solutions to the generalized combination network $(\varepsilon,\ell) - N_{h,r,\alpha,\ell,\varepsilon}$. We derived new upper and lower bounds on $r_{\text{max}}$, the maximum number of nodes in the middle layer, for a fixed network structure, thus getting bounds on the field size of the scalar/vector solution. Our lower bound is close (within a constant factor of $\gamma \approx 3.48$) to our upper bound for $h \leq 2\ell$ or $h \geq 2\ell, \alpha = 2$. We summarize the best known bounds on $r_{\text{max}}$ for different parameter ranges, in Table [4].

| Upper Bounds $h < 2\ell + \varepsilon$ | Reference $h \geq 2\ell + \varepsilon$ | Reference |
|--------------------------------------|----------------------------------------|--------------------------------------------|
| $\alpha > 2$ | $r_{\text{max}} \leq q^{(1/2)(t+1)}$ | Corollary [17] (see also Corollary [6]) | Corollary [1] |
| $\alpha = 2$ | $r_{\text{max}} \leq q^{(1/2)(t+1)}$ | Corollary [1] |
| Lower Bounds $h < 2\ell + \varepsilon$ | Reference $h \geq 2\ell + \varepsilon$ | Reference |
| $\alpha > 2$ | $r_{\text{max}} \geq (\alpha-1)q^{(t)}$ | Corollary [5] | $r_{\text{max}} \geq \beta \cdot q^{(t)}$ | Theorem [3] |

Remarks: The bounds are valid for $\alpha \geq 2, h, \ell \geq 1, \varepsilon > 0$. For non-trivially solvable generalized combination networks, $\ell + \varepsilon \leq h \leq \alpha \ell + \varepsilon$. The other parameters are $\gamma \approx 3.48$, $\beta = ((\alpha-1)/(2\gamma \alpha))^{1/((\alpha-1))}, f(t) = (\alpha\ell + \varepsilon - h)t^2 + (\alpha\ell + 2\varepsilon - h)t + 1, \theta = -[(h-\varepsilon)/\ell] + 1$, and $g(t) = \max\{\ell t, (h-\ell)t\} - (\ell t - \varepsilon t + 1)$.

Moreover, we studied the gap between the minimal field size of a scalar solution and a vector solution. Unlike previous works, e.g., [4], [16], which were focused on engineering the networks to obtain a high gap, we start by fixing network parameters (i.e., $\alpha, \ell, r, \alpha, \ell, \varepsilon$), and then provide bounds for its gap, which do not depend on $t$. Of particular interest is the conclusion from Corollary [4] and Corollary [5]: fixing the number of messages $h$, and parameters relating to the connectivity level of the network (i.e., $\alpha, \ell, \varepsilon$), we only vary the number of middle layer nodes, $r$, or equivalently, the number of receivers $N := \binom{\ell}{r}$, proving that the gap is $\text{gap}_2(N) = \Theta(\log r) = \Theta(\log N)$. Namely, the scalar linear solutions over-pays an order of $\log r$ extra bits per symbol to solve the network, in comparison to the vector linear solutions.

The novel upper and lower bounds on the gap cover all generalized network parameters, except $\varepsilon = 0$. This may imply that the direct links between the source and the terminals are crucial for vector network coding to have an advantage in generalized combination networks. The direct link in usual communication networks might not be practical, however, in some recent applications, such as coded caching, this direct link can be seen as the cached content at the receivers. The exact nature of the connection between direct links and field-size gap, is left for future work.
