Sporadic Occurrence of Enteroaggregative Shiga Toxin–Producing *Escherichia coli* O104:H4 Similar to 2011 Outbreak Strain

Claudia E. Coipan, Ingrid H. Friesema, Maaike J.C. van den Beld, Thijs Bosch, Sabine Schlager, Menno van der Voort, Christina Frank, Christina Lang, Angelika Fruth, Eelco Franz

We describe the recent detection of 3 Shiga toxin–producing enteroaggregative *Escherichia coli* O104:H4 isolates from patients and 1 from pork in the Netherlands that were genetically highly similar to isolates from the 2011 large-scale outbreak in Europe. Our findings stress the importance of safeguarding food supply production chains to prevent future outbreaks.

Shiga toxin–producing *Escherichia coli* (STEC) is a zoonotic pathogen that causes illness ranging from mild diarrhea to hemolytic uremic syndrome and death. During 2011, an exceptionally large outbreak caused by serotype O104:H4 STEC occurred in Europe, mainly in Germany and France, that was associated with sprouts grown from imported fenugreek seeds (1). Besides the ability to produce Shiga toxin, specifically *stx*2a, the strain had the genetic characteristics and phylogenetic backbone of an enteroaggregative *E. coli* (EAEC) pathotype (2) but lacked other classical STEC virulence markers *eae* and *hlyA* (3). In addition, the outbreak strain carried plasmid-borne *bla* _CTX-M-15_ and *bla* _TEM-1_ genes. The epidemiologic investigation revealed that a contaminated batch of fenugreek seeds imported into the European Union from Egypt was the most probable source of the pathogen causing the outbreak (4).

After the 2011 outbreak in Germany and France, only a few sporadic cases of infection with Shiga toxin–producing EAEC O104:H4 were reported, most related to travel to Turkey or North Africa (5–8). We describe the sporadic occurrence of Shiga toxin–producing EAEC O104:H4 isolates in the Netherlands, originating from 2 clinical cases from 2019 and 2020 and 1 food isolate from 2017. In addition, we report a clinical case from Austria in 2021.

The Study

Surveillance of Shiga toxin–producing *E. coli* (STEC) in the Netherlands is performed in 1 or both of 2 ways: by mandatory case notification from medical laboratories or physicians to regional public health services, which then report the cases to the Netherlands National Institute for Public Health and the Environment (RIVM), or by microbiological surveillance, when medical laboratories send suspected STEC isolates to RIVM for confirmation and further molecular characterization. Since 2016, STEC isolates have been subjected to whole-genome sequencing for high-resolution detection of clusters and outbreaks nationwide. During detailed retrospective analysis of the whole-genome sequencing data, we identified isolates from 2 clinical cases of STEC infection from 2019 and 2020 and characterized them as *stx*2a-encoding EAEC O104:H4 (isolates NL1981 and NL2076). Both cases involved middle-aged nonhospitalized women with abdominal cramps and bloody diarrhea. Neither of the 2 case-patients reported recent travel. The 2019 case-patient reported consuming cooked minced beef, and the 2020 case-patient reported consuming beef, hamburger meat, and vegetables and fruits from her own garden. In 2021, the Austrian Agency for Health and Food Safety obtained a sample of similar *stx*2a-encoding EAEC O104:H4 from a 10-year-old girl with hemolytic uremic syndrome. This case-patient also reported no recent travel, but she had consumed raw

DOI: https://doi.org/10.3201/eid2809.220037
We performed a genomic comparison among the recently identified isolates, 2 Shiga toxin–producing EAEC O104:H4 isolates in cases from the Netherlands from 2013 described elsewhere (8), and a set of representative isolates from a 2011 outbreak in Germany and France, including isolates from case-patients in Germany who shed the outbreak strain well into 2012 (long-term shedders). To achieve our full set of isolates (Table), we supplemented the dataset into 2012 (long-term shedders). To track possible evolutionary events. We assessed genomic relations between isolates by core- and accessory-genome multilocus sequence typing using the Enterobase STEC scheme implemented in Ridom Seqsphere version 8.0.1 (https://www.ridom.de). The resulting dendrogram was rooted with strain 1060_13, a Clermont type A isolate. The 2020 patient isolate from the Netherlands (NL2076) and the pork isolate (ESBL3427) clearly clustered with the representative outbreak isolates (Figures 1, 2). Conversely, patient isolates NL1981 from the Netherlands in 2019 and MRV-21-00239 from Austria in 2021 appeared more similar to each other and the 2 patient isolates (338 and 381_1) from the Netherlands in 2013 than to isolates from the outbreak cluster (Figures 1, 2).

We determined the content of the plasmid, virulence, and antimicrobial resistance genes using the PlasmidFinder, VirulenceFinder, and ResFinder databases (http://www.genomicSEQUENCING.com). Within the outbreak cluster, including the patient (NL2076) and pork (ESBL3427) strains from the

DISPATCHES

Netherlands, isolates showed virulence profiles typical of the 2011 outbreak strain, including STEC virulence markers stx2a, lpfA, and iha; the EAEC pAA plasmid (with agsR, aar, aap, sepA, the aatPABCD operon, and the aggABCD operon); and some chromosomal EAEC markers such as pic and sigA, but they lacked the STEC hallmark intimin eae. In addition, the isolates within the outbreak cluster showed similar antimicrobial resistance profiles, including blaCTX-M-15 and blaTEM-1B. Exceptions were the 2012 isolates from long-term shedders in Germany, which lost the pAA plasmid but belong to the outbreak cluster on the basis of their core genome (9) (Figure 1). Ancestral trait reconstruction as implemented in the R package ape v.5.5 (10), indicated a high likelihood that the most recent common ancestor of the isolates identified in this study were lysogenized with an stx-encoding phage. Among the isolates in the outbreak cluster, the core-genome allelic distance was 0–15 alleles (Figure 2).

Conclusions

After the 2011 outbreak in Europe, only a few sporadic cases of infection with stx-producing EAEC O104:H4 strains, most related to travel to Turkey or North Africa (8,11), were reported. The fact that the particular EAEC O104:H4 strains have never convincingly been isolated from food, animal, or environmental sources, and that EAEC in general are primarily human-adapted (12), support the hypothesis of a human reservoir and potential multiple events of import by travelers from an area where this pathogen is endemic. On the other hand, the loss of essential virulence markers in

Figure 1. Single-linkage hierarchical clustering tree of enteroaggregative Shiga toxin–producing Escherichia coli O104:H4 from the Netherlands and reference sequences. Tree results from core- and accessory-genome multilocus sequence typing with a heatmap indicating presence or absence of stx-encoding bacteriophage, plasmids, resistance, and virulence genes. Only genes present in at least 1 isolate are depicted. Colored isolates are those added during this study: green indicates the patient isolate from the Netherlands in 2020, purple the pork isolate from the Netherlands in 2017, blue the patient isolate from the Netherlands in 2019, orange the patient isolate from Austria in 2021. The stacked bar plots on a few selected branches in the tree indicate the likelihood at the downstream nodes of having contained an stx-encoding phage (black: absence, pink: presence). Enteroaggregative STEC long-term shedders might be a preview of common trends of bacterial genome reduction in long-term carriage in humans which, in turn, might indicate that the newly signaled isolates are maintained in niches other than the human one. Genomic analysis of several post-outbreak EAEC O104:H4 isolates suggests that they are not derived from the 2011 outbreak but share a recent common ancestor (13). Our analysis indicates that distinct more- or less-distant variants of Shiga toxin–producing EAEC O104:H4 are circulating worldwide. These variants are more likely to represent independent evolutionary events than continuous diversification of a single clade established and circulating in Europe after the large 2011 outbreak (14). In the absence of any previous indication of Shiga toxin–producing EAEC O104:H4 in animals, it was surprising to retrieve such an isolate from a pork product. However, this finding does not necessarily imply that pigs are a reservoir, because the contamination could also have originated from a food handler or contaminated feed rather than the pigs.

In conclusion, we show that Shiga toxin–producing EAEC O104:H4 isolates highly related to the 2011 outbreak strain are sporadically occurring in Europe. We emphasize the need to optimize safeguarding vulnerable chains of food production to prevent future outbreaks.

Acknowledgments
The authors thank GGD, the Dutch municipal health services, for interviewing the STEC case-patients and the MML medical laboratories for submitting STEC isolates for additional typing. We thank Kees Veldman for his assistance in tracking the food strain history, reculturing the strain for whole genome sequencing, and reviewing the manuscript.

About the Author
Dr. Coipan is a genomic epidemiologist in the department of epidemiology and surveillance of enteric infections and zoonoses. Her primary research focus is the integration of bioinformatics, microbial ecology, population genetics, and classical epidemiology to understand origins and spread of pathogens.

**Transovarial Transmission of Heartland Virus by Invasive Asian Longhorned Ticks under Laboratory Conditions**

Native to Southeast Asia, the Asian longhorned tick was reported in the United States during 2017 and has since been found in 17 states. In its native range, this tick is the main vector of Dabie bandavirus, a virus that is closely related to Heartland virus. Microinjected Asian longhorned ticks have been shown to transmit Heartland virus transovarially to their progeny, highlighting the need for continued Asian longhorned tick surveillance and testing.

In this EID podcast, Dr. Meghan Hermance, an assistant professor of microbiology and immunology at the University of South Alabama, discusses infection and transmission of Heartland virus in ticks in a lab.
