With the spread of coronavirus disease 2019 (COVID-19) in Korea, the number of pregnant women infected with severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) is rapidly increasing. A shortage of negative-pressure isolation rooms for newborns makes hospital assignment more difficult for late-pregnant women with COVID-19. Among 34 infants born to SARS-CoV-2-positive mothers, 5 (14.7%) presented with respiratory distress and 1 (2.9%) presented with feeding intolerance that required specialized care. Aerosol-generating procedures were performed in one infant. Overall outcomes of 34 infants were favorable, and no infant tested positive for SARS-CoV-2. Most infants born to SARS-CoV-2-positive mothers did not need to be quarantined in a negative-pressure isolation room, and 17 (50%) mother–infant dyads were eligible for rooming-in. If negative-pressure isolation rooms are selectively used for newborns requiring aerosol-generating procedures or newborns in respiratory distress, resource availability for lower-risk cases may improve.

Keywords: COVID-19; SARS-CoV-2; Pregnancy; Infant, Newborn; Disease Transmission, Infectious; Negative-Pressure Isolation
perinatal SARS-CoV-2 transmission and need for negative-pressure isolation rooms should be examined. This study aimed to describe clinical characteristics and hospital courses of infants born to SARS-CoV-2-positive mothers and suggest ways to resolve the shortage of isolation rooms in this context.

The management of labor and delivery of pregnant women with COVID-19 at the National Medical Center was based on the latest Korean Society of Pediatric Infectious Diseases guidelines. All mothers with COVID-19 delivered via cesarean section in isolation in a negative-pressure operating room. The newborn resuscitation area was 2 m away from the mother. Mothers wore masks during the delivery. After routine resuscitation (drying, stimulation, and suctioning) and additional resuscitative measures, as required, newborns were moved in a closed transport incubator to private negative-pressure rooms in the nursery and were separated from unaffected newborns. Newborn evaluation and care, SARS-CoV-2 testing, and criteria for discontinuing isolation were performed according to the latest guidelines. After 2 consecutive negative SARS-CoV-2 polymerase chain reaction (PCR) tests on nasopharyngeal and oropharyngeal samples at 24 hours and 48 hours after birth, newborns with maternal COVID-19 were released from quarantine and cared for with other newborns in the nursery until discharge. Infants were fed formula milk during maternal isolation.

Between December 2020 and December 2021, 34 women with gestational age ≥ 35 weeks delivered 34 newborns during their isolation period. According to the U.S. National Institutes of Health COVID-19 Treatment Guidelines criteria, 7 (20.6%) cases had severe COVID-19 before delivery and 5 (14.7%) cases progressed to severe illness after delivery. A total of 15 (44.1%) postpartum women had severe or critical COVID-19 or body temperature ≥ 38.0°C. Mother and newborn characteristics are presented in Table 1.

The median gestational age at birth was 38.3 weeks. Six (17.6%) infants were born preterm. No infants required advanced resuscitation such as chest compressions, positive-pressure ventilation, or medication at birth. During the hospital stay, 6 (17.6%) infants required specialized care. One infant with feeding intolerance required intravenous fluid therapy. Five infants had respiratory distress and required respiratory support: 4 with supplemental oxygen via a nasal cannula and 1 with nasal continuous positive airway pressure. The final diagnoses were transient tachypnea of the newborn (n = 3), delayed transition (n = 1), and meconium aspiration syndrome (n = 1). The infants with respiratory distress improved shortly and were weaned to room air within 48 hours of age. Overall, 17 (50.0%) mother–infant dyads (mothers with mild or moderate illness and without fever and infants not requiring specialized care) remained well during the entire hospitalization.

The SARS-CoV-2 PCR test results of all 34 newborns were negative at 24 hours and 48 hours after birth. After release from a median of 3 days (interquartile range, 2–3 days) of quarantine, the newborns were cared for in the nursery with non-COVID-19-exposed newborns. The 23 (67.6%) newborns stayed in the nursery until their mother was discharged. On follow-up phone calls made by nurses within 7 days after discharge, all infants remained in good condition and there were no additional confirmed cases of COVID-19 among them.

Previous reports on newborns of mothers with COVID-19 in Korea reported about 4 infants born at full term via cesarean section and immediately separated from their mothers. No infant tested positive for SARS-CoV-2. Our findings are consistent with those of previous case studies managed using a similar policy. Worldwide, the mother-to-infant transmission rate
Table 1. Demographic and clinical characteristics of late-preterm and full-term infants born to SARS-CoV-2-positive mothers

| Characteristics                                      | Values                                      |

Values are presented as median (interquartile range), number (%) or mean ± SD.
COVID-19 = coronavirus disease 2019, SARS-CoV-2 = severe acute respiratory syndrome coronavirus 2.
\(^a\)SARS-CoV-2 infection date was defined as the date of symptom onset or the first positive polymerase chain reaction test result, whichever came first.
\(^b\)Antibiotics used for surgical prophylaxis were excluded.
\(^c\)SARS-CoV-2 Illness Severity Criteria were adapted from the U.S. National Institutes of Health COVID-19 Treatment Guidelines. Mild Illness: Individuals with signs and symptoms of COVID-19 but without dyspnea or abnormal chest imaging. Moderate Illness: Individuals with evidence of lower respiratory disease during clinical assessment or imaging and an oxygen saturation (SpO\(_2\)) of ≥ 94% in room air at sea level. Severe Illness: Individuals with an SpO\(_2\) of < 94% in room air at sea level, a ratio of arterial partial pressure of oxygen to fraction of inspired oxygen (PaO\(_2\)/FiO\(_2\)) < 300 mm Hg, respiratory rate > 30 breaths/min, or lung infiltrates > 50%. Critical Illness: Individuals with respiratory failure, septic shock, and/or multiple organ dysfunction.
of SARS-CoV-2 is reported to be in the range of 7–13% based on studies published before the implementation of the current guidelines, potentially overestimating the true incidence. In contrast, U.S. studies with larger sample sizes reported virtually no mother-to-infant transmission of SARS-CoV-2, despite high rates of rooming-in and direct breastfeeding.

An infant born to a mother with COVID-19 and requiring neonatal intensive care and respiratory support should be admitted to a private room with the potential for negative room pressure or to one with a door. For an infant with mild respiratory distress, which does not require positive pressure ventilation, a private room may be an adequate preventive strategy. Under a more stringent policy, stable newborns with respiratory support of up to 2 L/min of oxygen via a nasal cannula can be placed in neutral pressure rooms with precautions. The proportion of infants requiring aerosol generating procedures (AGPs) is estimated to be in the range of < 12–15% and even lower for late-preterm and full-term infants. Because intrauterine infection of SARS-CoV-2 is rare, and the risk of postnatal transmission is low while rooming-in with appropriate precautions, the risk of airborne SARS-CoV-2 transmission in newborns, independently of being separated from the mother immediately after birth, is likely very low. If negative-pressure isolation rooms are selectively used for newborns requiring AGPs, resource availability for lower-risk cases may improve.

Half of the mother–infant dyads in our study remained well during their hospital stay. Rooming-in, if practiced, might have helped relieve the burden of hospital overcrowding because it requires a single patient room for the mother and infant. Mother-to-infant transmission of SARS-CoV-2 during rooming-in is rare, provided that adequate droplet and contact precautions are taken. In studies evaluating rooming-in for infants born to SARS-CoV-2-positive mothers, most mother–infant dyads safely roomed-in. Separating mothers and newborns may not be warranted to prevent SARS-CoV-2 transmission. Based on accumulating evidence and given the benefits of breastfeeding and mother–infant contact, many guidelines recommend rooming-in unless precluded by the mother or newborn condition. In general, mothers are eligible for rooming-in under the following conditions: no need for respiratory support or supplemental oxygen, body temperature < 38°C, stable vital signs, and ability to take care of the baby. Newborns are eligible for rooming-in when they are well-appearing, with a gestational age ≥ 35 weeks and birth weight ≥ 2,000 g, physical examination findings within normal limits, vital signs within the reference ranges, and skilled in feeding. Temporary separation of the newborn from the mother during hospital stay may be inevitable for either maternal or neonatal reasons. When rooming-in is interrupted, the newborn may be isolated in a private room unless AGPs are required.

Our study had some limitations. First, this was a single-center study. Our results should be interpreted with caution because they may have been influenced by the strict policy implemented at our institution. Second, this study did not include cases requiring neonatal intensive care for maternal or fetal indications, thus limiting the generalizability of the results to pregnant women with initially severe COVID-19 illness, with a gestation age of 21–34 weeks and early preterm infants, or with a high-risk fetus. Despite these limitations, this study presented data on the largest number of SARS-CoV-2-positive mother–newborn dyads in Korea to date. Furthermore, our study suggests that most infants with gestational age ≥ 35 weeks can be safely isolated in a private room and are clinically well enough to room-in with
their mother. A negative-pressure room can be spared for infants requiring AGPs. The change in isolation policy may help resolve the shortage of newborn isolation rooms and ensure safe delivery by mothers during the COVID-19 pandemic. Further multicenter studies with larger patient cohorts are required to elucidate the characteristics and outcomes of SARS-CoV-2-positive women and their newborns in South Korea.

**Ethics statement**

The Institutional Review Board of the National Medical Center approved this study (No. NMC-2021-12-144) and waived the written consent requirement.

**ACKNOWLEDGMENTS**

We would like to thank all of the staffs of the newborn nursery and delivery units of National Medical Center.
