The Efficacy of Pessimism in Asynchronous Q-Learning

Yuling Yan, Gen Li, Member, IEEE, Yuxin Chen, Senior Member, IEEE, and Jianqing Fan

Abstract—This paper is concerned with the asynchronous form of Q-learning, which applies a stochastic approximation scheme to Markovian data samples. Motivated by the recent advances in offline reinforcement learning, we develop an algorithmic framework that incorporates the principle of pessimism into asynchronous Q-learning, which penalizes infrequently-visited state-action pairs based on suitable lower confidence bounds (LCBs). This framework leads to, among other things, improved sample efficiency and enhanced adaptivity in the presence of near-expert data. Our approach permits the observed data in some important scenarios to cover only partial state-action space, which is in stark contrast to prior theory that requires uniform coverage of all state-action pairs. When coupled with the idea of variance reduction, asynchronous Q-learning with LCB penalization achieves near-optimal sample complexity, provided that the target accuracy level is small enough. In comparison, prior works were suboptimal in terms of the dependency on the effective horizon even when i.i.d. sampling is permitted. Our results deliver the first theoretical support for the use of pessimism principle in the presence of Markovian non-i.i.d. data.

Index Terms—Asynchronous Q-learning, offline reinforcement learning, pessimism principle, model-free algorithms, partial coverage, variance reduction.

I. INTRODUCTION

The asynchronous form of Q-learning, which is a stochastic approximation paradigm that applies to Markovian non-i.i.d. samples, has found applicability in an abundance of reinforcement learning (RL) applications [1], [2], [3], [4]. The input data takes the form of a Markovian sample trajectory induced by a policy called the behavior policy; in each time, asynchronous Q-learning only updates the Q-function estimate of a single state-action pair along the trajectory rather than updating all pairs at once — and hence the terminology “asynchronous” [2], [5]. This classical algorithm has the virtue of being off-policy, allowing one to learn the optimal policy even when the behavior policy is suboptimal. Recent years have witnessed a resurgence of interest in understanding the performance of asynchronous Q-learning, due to a shift of attention from classical asymptotic analysis to the non-asymptotic counterpart. By and large, non-asymptotic results bear important and clear implications for the impacts of salient parameters (e.g., model capacity, horizon length) in large-dimensional RL problems.

A. Motivation

A central consideration in modern RL applications is data efficiency: the limited availability of data samples places increasing demands on sample-efficient RL solutions, and in turn, calls for reexamining classical algorithms like Q-learning. When it comes to asynchronous Q-learning, recent theoretical advances have led to sharpened sample complexity analyses [6], [7], [8]. For concreteness, consider a $\gamma$-discounted infinite-horizon Markov decision process (MDP) and a stationary behavior policy: asynchronous Q-learning provably yields $\epsilon$-accuracy as soon as the sample size exceeds the order of $\frac{1}{\mu_{\text{min}}(1-\gamma)^{\frac{3}{2}} + o\left(\frac{1}{\epsilon^2}\right)}$ modulo some log factor, where $\mu_{\text{min}}$ stands for the minimum occupancy probability of the sample trajectory over all state-action pairs. While this bound (1) is tight in a general sense for vanilla Q-learning, two issues immediately spring into mind.

- Uniform coverage vs. partial coverage. The factor $1/\mu_{\text{min}}$ in (1) imposes a firm requirement on uniform coverage of the state-action space, namely, every state-action pair needs to be visited sufficiently often in order to guarantee reliable learning. Nevertheless, it is not uncommon for a behavior policy to provide only partial coverage of the state-action space; for instance, a behavior policy

\begin{equation}
\frac{1}{\mu_{\text{min}}(1-\gamma)^{\frac{3}{2}} + o\left(\frac{1}{\epsilon^2}\right)}
\end{equation}

\[1\]

Here, the higher-order term $o\left(\frac{1}{\epsilon^2}\right)$ depends also on other parameters of the MDP and of the sample trajectory (e.g., the mixing time, the discount factor, and $\mu_{\text{min}}$).

might elect to rule out several actions that are clearly underperforming. In truth, partial coverage of the state-action space results in \( \mu_{\min} = 0 \), thus making the general bound (1) vacuous in this case.

- **Lack of adaptivity to expert data.** The general bound (1) falls short of reflecting the quality of the sample trajectory (except for a general uniform coverage parameter \( \mu_{\min} \)). For instance, if the behavior policy is adopted by an “expert” who is already aware of which actions are (close to) optimal, then such expert data could be more informative than a general sample trajectory with the same \( \mu_{\min} \). It is therefore desirable for an algorithm to adapt automatically to the quality of the data, in the hope of achieving sample size saving when expert data is available.

### B. Main Contributions

This paper seeks to make asynchronous Q-learning adaptive to near-expert data, allowing for partial coverage of the state-action space in some important scenarios. A key idea that has been recently proposed to accommodate partial coverage in the presence of near-expert data is the principle of pessimism (or conservatism) in the face of uncertainty [9], [10], whose benefits have been established in the context of offline RL (or batch RL). In a nutshell, the pessimism principle penalizes the Q-function based on how infrequent a state-action pair is visited, which effectively directs the attention of an RL algorithm away from the under-covered part of the state-action space. However, it remains unclear how effective this idea of pessimism could be in the asynchronous setting when coping with Markovian data.

In order to address this issue, the current paper revisits asynchronous Q-learning in the presence of a Markovian sample trajectory generated by a behavior policy \( \pi_b \). We focus on a \( \gamma \)-discounted infinite-horizon MDP with \( S \) states and \( A \) actions, and suppose that the behavior policy is stationary and satisfies a certain single-policy concentrability assumption (associated with a test distribution \( \rho \)) with coefficient \( C^* \geq 1 \); informally, this means that the observed sample trajectory effectively becomes expert data as \( C^* \) approaches 1, as we shall formalize in Section II. Our contributions are two-fold; here and below, \( \tilde{O} ( \cdot ) \) stands for the orderwise upper bound while hiding any logarithmic dependency.

- **Asynchronous Q-learning with LCB penalization.** We propose a variant of asynchronous Q-learning by penalizing each Q-learning iteration based on a lower confidence bound (LCB). This variant of Q-learning achieves \( \varepsilon \)-accuracy (w.r.t. a test distribution \( \rho \)) as long as the total sample size is above the order of

\[
\tilde{O} \left( \frac{SC^*}{(1-\gamma)^3 \varepsilon^2} \right),
\]

provided that the accuracy level \( \varepsilon \) is small enough. Given that \( C^* \) can be as small as \( O(1) \) and given the trivial bound \( 1/\mu_{\min} \geq SA \) (so that \( (1) \geq \frac{SA}{1-\gamma^3(\frac{1}{2})} \)), our theory leads to sample size benefits in terms of its dependency on \( A \) when the data is near-expert.

- **Variance-reduced asynchronous Q-learning with LCB penalization.** While asynchronous Q-learning with LCB penalization allows for reduced sample complexity in the presence of near-expert data, the dependency on the effective horizon \( \frac{1}{1-\gamma} \) remains suboptimal. To address this, we leverage the idea of variance reduction (also called reference-advantage decomposition) [11], [12], [13] to further accelerate convergence of the algorithm, which in turn yields a sample complexity

\[
\tilde{O} \left( \frac{SC^*}{(1-\gamma)^5 \varepsilon^2} \right)
\]

for sufficiently small accuracy level \( \varepsilon \). The scaling \( \frac{1}{(1-\gamma)^5} \) is essentially unimprovable even for the synchronous setting with independent samples [10], [14]. Notably, none of the prior works on offline RL were able to achieve the scaling of \( \frac{SC^*}{(1-\gamma)^5} \); that is, the best-known theory [10] scales as \( \tilde{O} \left( \frac{SC^*}{(1-\gamma)^5} \right) \) and relies on i.i.d. sampling. Finally, we remark that the algorithmic and theoretical frameworks put forward herein are suitable for two important scenarios in the absence of active exploration of the environment: (i) online reinforcement learning with a time-invariant policy (so that the data arrives on the fly with no policy evolution), and (ii) offline reinforcement learning, where the data generated by the behavior policy has been pre-collected. In addition to the appealing sample complexity, model-free algorithms also enjoy the benefits of low memory and low computational complexity.

### II. MODELS AND ASSUMPTIONS

#### A. Basics of Infinite-Horizon Markov Decision Processes

In this paper, we consider an infinite-horizon Markov decision process, denoted by \( \mathcal{M} = (S, A, \gamma, P, r) \). Here, \( S \) represents the state space that contains \( S \) distinct states; \( A \) stands for the action space that contains \( A \) distinct actions; \( \gamma \in (0, 1) \) denotes the discount factor, with \( \frac{1}{1-\gamma} \) representing the effective horizon; \( P : S \times A \rightarrow \Delta(S) \) stands for the probability transition kernel (with \( \Delta(S) \) denoting the probability simplex over the set \( S \)), such that \( P(\cdot | s, a) \in \Delta(S) \) denotes the transition probability from state \( s \) when action \( a \) is executed; \( r : S \times A \rightarrow [0, 1] \) indicates the deterministic reward function, such that \( r(s, a) \) is the immediate reward gained in state \( s \) upon execution of action \( a \). We assume throughout that the immediate rewards fall within the range \([0, 1]\).

Let \( \Delta(A) \) be the probability simplex over the set \( A \). A policy \( \pi : S \rightarrow \Delta(A) \) is an action selection rule, such that \( \pi(\cdot | s) \in \Delta(A) \) specifies the action selection probability in state \( s \). When \( \pi \) is deterministic, we often overload the notation and let \( \pi(s) \) represent the action selected in state \( s \). The value function and the Q-function of policy \( \pi \) are defined respectively as

\[
V^{\pi}(s) := E \left[ \sum_{t=0}^{\infty} \gamma^t r(s_t, a_t) \mid s_0 = s \right],
\]

\[
Q^{\pi}(s, a) := E \left[ \sum_{t=0}^{\infty} \gamma^t r(s_t, a_t) \mid s_0 = s, a_0 = a \right],
\]
for all \((s, a) \in S \times A\), where the expectation is taken over a random trajectory \((s_0, a_0, s_1, a_1, s_2, a_2, \cdots)\) induced by the MDP \(M\) when policy \(\pi\) is employed. For a given initial state distribution \(\rho \in \Delta(S)\), we can also overload the notation of the value function to represent a certain average value function:

\[
V^\pi(\rho) := \mathbb{E}_{s \sim \rho}[V^\pi(s)].
\]

Moreover, it is well known that there exists at least one \textit{deterministic} policy, denoted by \(\pi^*\), that simultaneously maximizes the value function and the Q-function over all state-action pairs. Therefore, we introduce the following notation

\[
V^*(s) := \max_{\pi} V^\pi(s), \quad V^*(\rho) := \mathbb{E}_{s \sim \rho}[V^*(s)],
\]

and

\[
Q^*(s, a) := \max_{\pi} Q^\pi(s, a)
\]

to represent the optimal value function and the optimal Q-function. Given a test distribution \(\rho \in \Delta(S)\) and a target accuracy level \(\varepsilon \in (0, \frac{1}{1-\gamma})\), our aim is to develop a policy \(\tilde{\pi}\) obeying

\[
V^*(\rho) - V^{\tilde{\pi}}(\rho) \leq \varepsilon.
\]

A kind of distributions that plays an important role in our theory is the discounted state-action occupancy distribution defined as follows: for all \((s, a) \in S \times A\),

\[
d_\rho^\pi(s, a) := (1 - \gamma) \sum_{t=0}^{\infty} \gamma^t \mathbb{P}(s_t = s, a_t = a \mid \pi, s_0 \sim \rho),
\]

\[
d_\rho^\pi(s) := (1 - \gamma) \sum_{t=0}^{\infty} \gamma^t \mathbb{P}(s_t = s \mid \pi, s_0 \sim \rho),
\]

where the trajectory \((s_0, a_0, s_1, a_1, s_2, a_2, \cdots)\) is induced by the MDP under the policy \(\pi\) and a given initial state distribution \(\rho\). When \(\pi\) coincides with the optimal policy \(\pi^*\), we abbreviate

\[
d_\rho^\pi(s, a) := d_\rho^\pi(s, a), \quad d_\rho^\pi(s) := d_\rho^\pi(s, \pi^*(s))
\]

for all \((s, a) \in S \times A\).

### B. Sampling Mechanism

Suppose that the observed Markovian sample trajectory \(\{(s_t, a_t)\}_{t \geq 0}\) is obtained by executing a behavior policy \(\pi_b\) in the MDP \(M\). We say that the total sample size is \(T\) if the algorithm employs \(T\) state-action pairs of this trajectory, i.e., \(\{(s_t, a_t)\}_{0 \leq t \leq T}\). Assume that \(\mu_b(s, a)\) is the stationary distribution of the Markov chain generated by \(\pi_b\), with the minimum state-action occupancy probability defined to be

\[
\mu_{\min} := \min_{s \in S, a \in A} \mu_b(s, a).
\]

We impose the following assumptions on \(\pi_b\) throughout this paper.

**Assumption 1:** The behavior policy \(\pi_b\) is stationary, and the Markov chain induced by \(\pi_b\) is uniformly ergodic.

**Remark 1:** In words, uniform ergodicity says that for any initial state-action pair, the total-variation distance between the distribution of \((s_t, a_t)\) and the stationary distribution of the chain decays geometrically in \(t\); see [15, Definition 1.1] for a precise definition of uniform ergodicity.

Furthermore, for a given test distribution or initial state distribution \(\rho \in \Delta(S)\), we adopt the following concept as introduced in [10].

**Assumption 2 (Single-policy concentrability):** Suppose that there exists some constant \(C^* \geq 1\) such that

\[
\forall (s, a) \in S \times A : \quad \frac{d_\rho^\pi(s, a)}{\mu_b(s, a)} \leq C^*,
\]

where we define \(0/0 = 0\) by convention. Throughout this paper, \(C^* \geq 1\) is called the single-policy concentrability coefficient.

In some sense, the single-policy concentrability coefficient measures the closeness between the stationary distribution of the observed data and a certain occupancy distribution induced by the optimal policy. In particular, if we take \(\rho = \mu^*\) to be the stationary state distribution of the MDP under the deterministic policy \(\pi^*\), then it can be easily verified that \(d_\rho^\pi(s, a) = \mu^*(s) \mathbb{1}\{\pi^*(s) = a\}\), allowing us to rewrite (2) w.r.t. the density ratio of two stationary distributions as follows:

\[
\forall s \in S : \quad \frac{\mu^*(s)}{\mu_b(s, \pi^*(s))} \leq C^*.
\]

In this paper, the sample data is said to be near-expert if \(C^* = O(1)\), as in this case the empirical distribution of the sample data is not far away from what is induced by the optimal policy. Note that the introduction of the single-policy concentrability coefficient \(C^*\) is solely for the purpose of theoretical analysis, and the algorithms proposed herein do not require prior knowledge of \(C^*\) at all. It is also worth noting that \(C^*\) (cf. (2)) is a function of the test distribution \(\rho\) as well, although we suppress this dependency in the notation \(C^*\) for the sake of conciseness.

Another important quantity that affects the performance of our model-free algorithms is the mixing time associated with the sample trajectory. To be precise, for any \(0 < \delta < 1\), the mixing time of the Markov chain induced by the MDP \(M\) under behavior policy \(\pi_b\) is defined as

\[
t_{\text{mix}}(\delta) := \min \left\{ t : \max_{s_0 \in S, a_0 \in A} d_{\text{TV}}(P^t(\cdot \mid s_0, a_0), \mu_b) \leq \delta \right\}.
\]

Here, \(P^t(\cdot \mid s_0, a_0)\) stands for the distribution of \((s_t, a_t)\) (i.e., the state-action pair in the \(t\)-th step of the trajectory) when the chain is initialized to \((s_0, a_0)\), whereas \(d_{\text{TV}}(\mu, \nu)\) is the total-variation distance between two distributions \(\mu\) and \(\nu\) over a discrete space \(\mathcal{X}\) [16], namely

\[
d_{\text{TV}}(\mu, \nu) = \frac{1}{2} \sum_{x \in \mathcal{X}} |\mu(x) - \nu(x)| = \sup_{B \subseteq \mathcal{X}} |\mu(B) - \nu(B)|.
\]

In particular, we shall abbreviate

\[
t_{\text{mix}} := t_{\text{mix}}(1/4),
\]

following the convention in prior works like [15]. Clearly, this important quantity measures how long it takes for a Markov chain to decorrelate itself from the initial state.
Remark 2: Another simpler sampling mechanism studied in prior literature (e.g., [10]) is i.i.d. sampling, under which the observed sample trajectory takes the form of \( \{(s_t, a_t, s'_t)\}_1 \leq t \leq T \) with

\[
(s_t, a_t) \sim \pi_b \quad \text{and} \quad s'_t \sim P(\cdot | s_t, a_t), \quad 1 \leq t \leq T
\]

independently generated. It is worth mentioning that the theorems and analysis in the current paper automatically apply to i.i.d. sampling by taking \( t_{mix} = 1 \). Clearly, the Markovian sample trajectory studied herein is in general more challenging to cope with, due to the complicated Markovian dependency.

III. ASYNCHRONOUS Q-LEARNING

WITH LCB PENALIZATION

In this section, we describe how to incorporate the pessimism principle into classical asynchronous Q-learning, accompanied by our theoretical performance guarantees.

A. Algorithm

We introduce the key algorithmic ingredients of our first algorithm: asynchronous Q-learning with LCB penalization. The complete details can be found in Algorithm 1.

1) Asynchronous Q-Learning: Let us begin by reviewing the basics of asynchronous Q-learning, which maintains iterates \( \{Q_t\} \) as the Q-function estimates. In each iteration \( t \), the algorithm takes action \( a_{t-1} \sim \pi_b(\cdot | s_{t-1}) \), observes the next state \( s_t \sim P(\cdot | s_{t-1}, a_{t-1}) \), and then updates its Q-function estimate w.r.t. a single state-action pair \((s_{t-1}, a_{t-1})\) as follows

\[
Q_t(s_{t-1}, a_{t-1}) = (1 - \eta_n)Q_{t-1}(s_{t-1}, a_{t-1}) + \eta_n \left\{ r(s_{t-1}, a_{t-1}) + \gamma V_{t-1}(s_t) \right\},
\]

\[
Q_t(s, a) = Q_{t-1}(s, a), \quad \forall (s, a) \neq (s_{t-1}, a_{t-1}).
\]

Here, \( n \) represents the number of visits to \((s_{t-1}, a_{t-1})\) prior to the \( t \)-th iteration, \( 0 < \eta_n < 1 \) stands for the learning rate, and the value function estimate is defined to be \( V_{t-1}(s) := \max_{a \in A} Q_{t-1}(s, a) \).

2) The Pessimism Principle and LCB Penalization: In order to accommodate under-coverage of the state-action space in the presence of near-expert data, a key idea is to penalize the Q-function of those state-action pairs that are rarely visited (i.e., the ones that are not favored by the “expert”), so as to downplay their influence on the Q-estimates. Specifically, in the \( t \)-th iteration, we modify the Q-learning update by inserting a penalty term \( b_n \):

\[
Q_t(s_{t-1}, a_{t-1}) = (1 - \eta_n)Q_{t-1}(s_{t-1}, a_{t-1}) + \eta_n \left\{ r(s_{t-1}, a_{t-1}) + \gamma V_{t-1}(s_t) - b_n \right\},
\]

and

\[
Q_t(s, a) = Q_{t-1}(s, a), \quad \forall (s, a) \neq (s_{t-1}, a_{t-1}),
\]

where the penalty term \( b_n \) is chosen to be some lower-confidence bound (LCB) determined by the Hoeffding concentration inequality. More precisely, we shall set

\[
b_n = C_b \sqrt{\frac{H \log (ST/\delta)}{n (1 - \gamma)^2}},
\]

throughout this paper, where we take \( H = \lceil 4 \gamma \log \frac{ST}{\delta} \rceil \) — so that \( b_n \) is on the order of \( \tilde{O} \left( \frac{1}{(1 - \gamma)^3 \delta^3} \right) \) — and recall that \( n \) is the number of visits to \((s_{t-1}, a_{t-1})\) prior to time \( t \). The rationale behind this specific choice will be made clear in the analysis.

3) Monotonicity of Value Function Estimates: In addition to the above pessimism principle, another consideration is to ensure that the value function estimate \( V_t \) always improves upon (or at least, is no worse than) the previous estimate. Towards this end, we take

\[
V_t(s_{t-1}) = \max \left\{ \max_{a \in A} Q_t(s_{t-1}, a), \ V_{t-1}(s_{t-1}) \right\},
\]

\[
V_t(s) = V_t(s_{t-1}) \quad \text{for all } s \neq s_{t-1},
\]

which yields monotonically non-decreasing value function estimates \( \{V_t\}_{t \geq 0} \). This simple modification facilitates analysis while ensuring that \( V_t(s) \) is always non-negative (as long as we initialize \( V_t(s) \geq 0 \) for all \( s \in S \)).

4) Computational and Memory Complexities: The whole algorithm, as summarized in Algorithm 1 has low runtime \( O(T) \) and low memory complexity \( O(\min \{T, SA\}) \) (note that if a state-action pair is never visited, we do not need to record/update any quantity related to it).

B. Theoretical Guarantees

Equipped with LCB penalization, asynchronous Q-learning is capable of achieving appealing sample efficiency, even though the observed sample trajectory might not provide full coverage of the state-action space. This is stated in the following theorem, whose proof is postponed to Appendix B.

Theorem 1: Suppose that Assumptions 1 and 2 hold, and recall that \( T \) is the total number of samples. With probability exceeding \( 1 - \delta \), the policy \( \tilde{\pi} \) returned by Algorithm 1 satisfies

\[
V^*(\rho) - V^*(\tilde{\pi}) \lesssim \sqrt{\frac{C^* S^2}{T (1 - \gamma)^5}} + \frac{C^* S T_{max}^t}{T (1 - \gamma)^2} + \frac{C^* T_{max}^2}{T (1 - \gamma)^3},
\]

where \( t := \log(T/\delta) \).

By taking the right-hand side of (6) to be bounded above by \( \varepsilon \), we immediately see that Algorithm 1 achieves \( \varepsilon \)-accuracy with high probability, as long as the total sample size \( T \) exceeds

\[
\tilde{O} \left( \frac{SC^*}{(1 - \gamma)^5 \varepsilon^2} + \frac{(S + \frac{1}{1 - \gamma}) T_{min} C^*}{(1 - \gamma)^2 \varepsilon^2} \right).
\]

This also means that the sample complexity of Algorithm 1 scales as

\[
\tilde{O} \left( \frac{SC^*}{(1 - \gamma)^5 \varepsilon^2} \right)
\]

for any target accuracy level \( 0 < \varepsilon \leq \frac{S}{(S + \frac{1}{1 - \gamma}) T_{min}} \).

When we have near-expert data (so that \( C^* = O(1) \)), the sample complexity can be as low as

\[
\tilde{O} \left( \frac{S}{(1 - \gamma)^5 \varepsilon^2} \right).
\]
Algorithm 1 Asynchronous Q Learning With LCB Penalization.

Input: number of iterations $T$, initial state $s$.

Initialize: $Q_0(s, a) = 0$, $V_0(s) = 0$, $n_0(s, a) = 0$ for all $(s, a) \in S \times A$, $H = \lceil \frac{4}{\gamma^4} \log \frac{ST}{\delta} \rceil$.

for $t = 1$ to $T$ do

\[ \text{Draw } a_{t-1} \sim \pi_0(\cdot | s_{t-1}), \text{ and observe } s_t \sim P(\cdot | s_{t-1}, a_{t-1}). \]

Let $n_t(s_{t-1}, a_{t-1}) = n_{t-1}(s_{t-1}, a_{t-1}) + 1$; and $n_t(s, a) = n_{t-1}(s, a)$, $\forall (s, a) \neq (s_{t-1}, a_{t-1})$.

Set $n \leftarrow n_t(s, a)$, and take $\eta_n = (H + 1)/(H + n)$.

Update

\[ Q_t(s_{t-1}, a_{t-1}) = (1 - \eta_n) Q_{t-1}(s_{t-1}, a_{t-1}) + \eta_n \left\{ r(s_{t-1}, a_{t-1}) + \gamma V_{t-1}(s_t) - b_n \right\} \]

and $Q_t(s, a) = Q_{t-1}(s, a)$ for all $(s, a) \neq (s_{t-1}, a_{t-1})$, where

\[ b_n = C_0 \sqrt{H \log (ST/\delta)/(n - 1) \gamma^2} \]

for some sufficiently large constant $C_0 > 0$.

Update

\[ V_t(s_{t-1}) = \max_{a \in A} Q_t(s_{t-1}, a), \quad V_{t-1}(s_{t-1}) \]

and $V_t(s) = V_{t-1}(s)$ for all $s \neq s_{t-1}$.

Output: $\hat{\pi}$ such that $\hat{\pi}(s) = \arg \max_{a \in A} Q_T(s, a)$ for all $s \in S$.

In comparison, the general bound (1) developed in the previous literature requires at least $\frac{SA}{(1 - \gamma)^2}$ samples (since $1/h_{\min} \geq SA$) regardless of what behavior policy is employed. As a result, the proposed algorithm enjoys enhanced adaptivity to near-expert data, particularly in the presence of large action space and/or partial coverage.

It is worth noting, however, that the bound (8) exhibits a dependency $\frac{1}{(1 - \gamma)^2}$ on the effective horizon as opposed to $\frac{1}{1 - \gamma^2}$, due to the adoption of the Hoeffding-style penalty (5). This is potentially improvable by designing more careful Bernstein-style penalty (akin to [17, Section 3]). Nevertheless, we do not pursue this for two reasons: (a) the Hoeffding-style penalty streamlines analysis; (b) the Bernstein-style penalty alone is insufficient to yield optimal sample complexity, and we shall put forward another algorithm momentarily to achieve sample optimality.

IV. VARIANCE-REDUCED ASYNCHRONOUS Q-LEARNING WITH LCB PENALIZATION

As we have alluded to previously, the algorithm presented in Section III falls short of achieving optimal dependency on the effective horizon. To address this issue, a plausible idea is to leverage the variance reduction technique — originally introduced in finite-sum stochastic optimization [18] and imported to online RL recently [12] — to further accelerate convergence of the algorithm. This section is devoted to the development of a new variant of asynchronous Q-learning that incorporates both pessimism and variance reduction.

A. Algorithm

We start by describing the key ideas of a variance-reduced variant of Algorithm 1. This algorithm enjoys the same computational cost (i.e., $O(T)$) and memory complexity (i.e., $O(SA)$) as Algorithm 1, with full details are summarized in Algorithm 2 (in conjunction with Algorithms 3 and 4).

1) Variance Reduction: Suppose for the moment that we have access to a “reference” value function estimate $\overline{V}$ that is hopefully not far away from the true optimal value $V^\star$. Let us employ a batch of samples — more concretely, a total number of $T_{\text{ref}}$ consecutive samples $\{(s_{i_{\text{ref}}}, a_{i_{\text{ref}}}, s_{i+1}); 0 \leq i < T_{\text{ref}}\}$ — to compute an empirical estimate $\hat{P}_i : S \times A \rightarrow \Delta(S)$ of the probability transition kernel $P$. We can then incorporate variance reduction into the update rule (4) of Algorithm 1 as follows:

\[ Q_i(s_{t-1}, a_{t-1}) = (1 - \eta_n) Q_{i-1}(s_{t-1}, a_{t-1}) + \eta_n \left\{ r(s_{t-1}, a_{t-1}) + \gamma V_{i-1}(s_t) - b_n \right\} \]

\[ + \gamma \langle \hat{P}_i(\cdot | s_{t-1}, a_{t-1}), \nabla \rangle - b_n (s_{t-1}, a_{t-1}) \right\}. \quad (9) \]

Here, the penalty term $b_n(s_{t-1}, a_{t-1})$ is set to be a certain data-driven lower confidence bound tailored to this variance-reduced update rule. In particular, this penalty term is chosen to track the uncertainty of both the “advantage term” $V_{i-1}(s_t) - V(s_t)$ and the “reference term” $\langle \hat{P}_i(\cdot | s_{t-1}, a_{t-1}), \nabla \rangle$, inspired by the reference-advantage decomposition introduced in [12]; see Algorithm 4 for a precise description. As can be anticipated, if $\overline{V}$ is a more accurate estimate of $V^\star$ than $V_{i-1}$ (i.e., $\overline{V} \approx V^\star$), then the main stochastic term $V(s_t)$ (or $V_{i-1}(s_t)$) in $H^\star(s_t)$ in (9) is expected to be much less volatile than the counterpart $V_{i-1}(s_t)$ in (4), thus resulting in substantial variance reduction and hence accelerated convergence. It remains to develop a plausible approach that produces such reliable “reference” value function estimates.
Algorithm 2 Variance-Reduced Asynchronous Q-Learning With LCB Penalization.

**Input:** number of iterations $T$, initial state $s$.

**Initialize:** $V(s) = 0$ for all $s \in S$, $K = \lfloor \log_4(3T/4) \rfloor$.

for $k = 1$ to $K$ do
  Set $T^e_k = 4^k - 1$ and $T_k = 3 \cdot 4^{k-1}$.
  Call function Empirical-transition($T^e_k, V, s$) (cf. Algorithm 3) and return $(\tilde{P}, \tilde{b}^{ref}, s_1)$.
  Call function VR-Q.epoch($T_k, V, \tilde{P}, \tilde{b}^{ref}, s_1$) (cf. Algorithm 4) and return $(Q, V, s_2)$.
  Update the reference $V = V$, and set the initial state in the next epoch as $s = s_2$.

**Output:** $\tilde{\pi}$ such that $\tilde{\pi}(s) = \arg\max_{a \in A} Q(s,a)$ for all $s \in S$.

Algorithm 3 Empirical-transition($T^{ref}, V, s^{ref}$)

**Input:** number of samples $T^{ref}$, reference $V$, initial state $s^{ref}$.

**Initialize:** $n^{ref}(s,a) = 0$ for all $(s,a) \in S \times A$, $\nu = \log \frac{ST}{T^{ref}}$.

for $t = 1$ to $T^{ref}$ do
  Draw $a_t^{ref} \sim \pi_0(\cdot | s_t^{ref})$, and observe $s_t^{ref} \sim P(\cdot | s_{t-1}^{ref}, a_{t-1}^{ref})$.
  Let $n^{ref}(s_{t-1}^{ref}, a_{t-1}^{ref}) \leftarrow n^{ref}(s_{t-1}^{ref}, a_{t-1}^{ref}) + 1$.
  Set $n^{ref}(s_{t-1}^{ref}, a_{t-1}^{ref}) = n^{ref}(s_{t-1}^{ref}, a_{t-1}^{ref}) + 1$.
  Compute the penalty term: for each $(s,a) \in S \times A$, take
  
  $$b^{ref}(s,a) = C_b \left( \sqrt{\frac{\sigma^{ref}(s,a) - [\mu^{ref}(s,a)]^2}{n^{ref}(s,a)}} + \frac{\nu^{3/4}}{(1-\gamma)[n^{ref}(s,a)]^{3/4}} + \frac{\nu}{(1-\gamma)n^{ref}(s,a)} \right)$$

  for some sufficiently large constant $C_b > 0$.

**Output:** empirical probability transition $\tilde{P}$, penalty $b^{ref}$, last state $s^{ref}$.

2) An Epoch-Based Paradigm: The proposed algorithm proceeds in an epoch-based manner ($K = \lfloor \log_4(3T/4) \rfloor$ epochs in total). In the $k$-th epoch, we use the value function estimate at the end of the previous epoch as the reference function estimate $\tilde{V}$; the number of samples used to construct the empirical transition kernel and the number of samples employed to run the updates (9) are denoted respectively by $T^e_k$ and $T_k$, both of which are chosen to grow exponentially with the epoch number $k$ (more specifically, we shall choose $T^e_k = 4^k - 1$ and $T_k = 3 \cdot 4^{k-1}$). Such choices allow one to ensure that: (i) the estimation error keeps improving over epochs; and (ii) the samples used in the latest epoch always account for roughly 3/4 of the total sample size used so far, thus mitigating inefficient use of samples despite the lack of sample reuse.

B. Theoretical Guarantees

Armed with the variance reduction idea, we are able to further improve the sample complexity in terms of the dependency on $\frac{1}{\gamma}$, as stated below. The proof can be found in Appendix D.

**Theorem 2:** Suppose that Assumptions 1 and 2 hold, and recall that $T$ is the total number of samples. Assume that $1/2 \leq \gamma < 1$. Then with probability exceeding $1 - \delta$, the policy $\tilde{\pi}$ returned by Algorithm 2 satisfies

$$V^*(\rho) - V^{\tilde{\pi}}(\rho) \lesssim \sqrt{\frac{SC^* \nu}{T(1-\gamma)^3}} + \frac{SC^* \nu^2}{T(1-\gamma)^4} + \frac{S\tau_{mix} C^* \nu}{T(1-\gamma)^2} + \frac{\nu^{3/4}}{(1-\gamma)[n^{ref}(s,a)]^{3/4}} + \frac{\nu}{(1-\gamma)n^{ref}(s,a)} \right).$$

where $\nu := \log \frac{ST}{T^{ref}}$.

Theorem 2 asserts that the sample size needed for Algorithm 2 to achieve $\varepsilon$-accuracy is at most

$$O \left( \frac{SC^*}{(1-\gamma)^3 \varepsilon^2} + \frac{SC^*}{(1-\gamma)^2 \varepsilon} + \frac{SC^* \tau_{mix} C^*}{(1-\gamma)^2} + \frac{\tau_{mix} C^*}{(1-\gamma)^3} \varepsilon \right).$$

In particular, if the accuracy level $\varepsilon \leq \min \{ \frac{1}{\gamma}, \frac{1}{\tau_{mix}}, \frac{1}{(1-\gamma) \tau_{mix}} \}$, then the sample complexity of Algorithm 2
Algorithm 4 VR-Q-epoch($T, \bar{V}, \bar{P}, b^{ref}, s_0$)

**Input:** number of iterations $T$, reference $\bar{V}$, transition kernel $\bar{P}$, penalty $b^{ref}$, initial state $s_0$.

**Initialize:** $Q_0(s, a) = 0$, $V_0(s) = 0$, $n_0(s, a) = 0$ for all $(s, a) \in S \times A$, $t = \log \frac{ST}{a}$, $H = \lfloor \frac{4}{1-\gamma} \rfloor$.

for $t = 1$ to $T$ do

1. Draw $a_{t-1} \sim \pi_{b}(\cdot | s_{t-1})$, and observe $s_t \sim P(\cdot | s_{t-1}, a_{t-1})$.
2. Let $n_t(s_{t-1}, a_{t-1}) \leftarrow n_t(s_{t-1}, a_{t-1}) + 1$; and $n_t(s, a) \leftarrow n_t(s, a)$ for all $(s, a) \neq (s_{t-1}, a_{t-1})$.
3. Set $\eta_t = (H + 1)/(H + n_t)$.
4. Set $\mu^m_{n-1}(s, a) = \mu^m_{n-1}(s, a)$ and $\sigma^m_{n-1}(s, a) = \sigma^m_{n-1}(s, a)$ for all $(s, a) \neq (s_{t-1}, a_{t-1})$; update
   
   $\mu^m_{n-1}(s_{t-1}, a_{t-1}) = (1 - \eta_t) \mu^m_{n-1}(s_{t-1}, a_{t-1}) + \eta_t \left[ V_{t-1}(s_t) - \bar{V}(s_t) \right]$,  
   
   $\sigma^m_{n-1}(s_{t-1}, a_{t-1}) = (1 - \eta_t) \sigma^m_{n-1}(s_{t-1}, a_{t-1}) + \eta_t \left[ V_{t-1}(s_t) - \bar{V}(s_t) \right]^2$.

5. Compute $Q_{n-1}(s_{t-1}, a_{t-1}) = \sigma^m_{n-1}(s_{t-1}, a_{t-1}) - [\mu^m_{n-1}(s_{t-1}, a_{t-1})]^2$.

6. Update

   $Q_t(s_{t-1}, a_{t-1}) = (1 - \eta_t) Q_{t-1}(s_{t-1}, a_{t-1}) + \eta_t \left\{ r(s_{t-1}, a_{t-1}) + \gamma V_{t-1}(s_t) - \gamma \bar{V}(s_t) + \gamma \langle \bar{P}(\cdot | s_{t-1}, a_{t-1}), \bar{V} \rangle - b_n \right\}$.

7. and $Q_t(s, a) = Q_{t-1}(s, a)$ for all $(s, a) \neq (s_{t-1}, a_{t-1})$, where $b_n = b^{ref}(s_{t-1}, a_{t-1}) + b^{adv}$ and

   $b^{adv} = C_b \left( \sqrt{\frac{H t}{n} s^{adv}_{n-1}(s_{t-1}, a_{t-1})} - \frac{1}{\eta_t} s^{adv}_{n-1}(s_{t-1}, a_{t-1}) \right) + \frac{H^3/4}{n^{3/4} (1 - \gamma)} + \frac{H t}{n (1 - \gamma)}$.

8. for some sufficiently large constant $C_b > 0$.

   Update

   $V_t(s_{t-1}) = \max \left\{ \max_{a \in A} Q_t(s_{t-1}, a), V_{t-1}(s_{t-1}) \right\}$.

   and $V_t(s) = V_{t-1}(s)$ for all $s \neq s_{t-1}$.

**Output:** Q-function estimate $Q_T$, value function estimate $V_T$, last state $s_T$.

This bound is essentially unimprovable; in fact, even for the simpler i.i.d. sampling mechanism described in Remark 2 (which can be viewed as a sample trajectory with $t_{mix} = 1$), a lower bound has been established by [10] that coincides with (11) when $C^* = O(1)$.

All this confirms the efficacy of the pessimism principle in conjunction with variance reduction when running model-free algorithms.

Let us take a moment to compare our setting and results with several offline RL papers that are most relevant to our work. Reference [19] (resp. the concurrent paper [20]) proposed a model-based algorithm called PEVI-ADV (resp. a model-free algorithm called LCB-Q-ADV) to learn the optimal policy from a collection of independent episodes of offline samples, both of which achieve optimal sample complexity $O(\varepsilon^{-2} H^{3} C^*)$ for finite-horizon MDPs with nonstationary transition kernels. In comparison, the current paper focuses on asynchronous Q-learning in a stationary discounted infinite-horizon MDP with data taking the form of a Markovian sample trajectory induced by a behavior policy, which is drastically different from and technically more challenging (e.g. i.i.d. data vs. Markovian non-i.i.d. data) than [19] and the concurrent work [20]. In addition, the problem studied in [10] can be viewed as a special case of our paper, given the i.i.d. nature of the sampling mechanism assumed therein. Reference [10] derived a sample complexity upper bound $O(\frac{SC^*}{(1-\gamma)^3 \varepsilon^2})$, which is suboptimal by a factor of $(1-\gamma)^{-2}$ compared to our result in Theorem 2. Another concurrent paper [21] studied the model-based approach (i.e. the VI-LCB algorithm), which contrasts sharply with the model-free algorithms considered herein. It is as noteworthy that the results in [21] fall short of handling Markovian non-i.i.d. data.

In addition, the last two terms in our sample complexity bound (10) rely on the mixing time. To examine the necessity of the term $\frac{SC^* t_{mix}}{(1-\gamma)^3 \varepsilon^2}$ in (10), we proceed to develop a minimax lower bound as follows; the proof is postponed to Appendix F.

**Theorem 3:** Consider any $S \geq 16$, $\gamma \in [1/2, 1)$, and $t_{mix} \geq \frac{10}{1-\gamma}$. Define the following set

$$\mathcal{M} := \left\{ (M, \rho, \pi_b) \mid |S| = S, |A| = 2, \rho \in \Delta(S), \pi_b : S \rightarrow \Delta(A), C^* \leq 3, \text{the mixing time of the Markov Chain induced by } \pi_b \text{ and } M \text{ is at most } 2t_{mix} \right\}.$$
There exists some universal constants $c_1, c_2 > 0$ such that, for any $\varepsilon \in (0, \frac{c_1}{1 - \gamma})$, if the sample size obeys
\[ T \leq c_2 \frac{S \text{mix}}{(1 - \gamma)\varepsilon}, \]
then with probability at least 0.5, one has
\[ \inf \sup_{\pi} \{ V^*(\rho) - \hat{V}(\rho) \} \geq \varepsilon. \]

Here, the infimum is over all policy estimator $\hat{\pi}$ for the optimal policy based on the observed sample trajectory.

In a nutshell, Theorem 3 reveals that when $S \geq \frac{1}{1 - \gamma}$ — a scenario that arises frequently in real-world applications — the dependence of our sample complexity (10) on the mixing time is at most loose by a factor of $\frac{1}{1 - \gamma}$. Unfortunately, our current theory falls short of characterizing the tight dependency of the mixing-time effect on $\frac{1}{1 - \gamma}$; a new suite of analysis tools might be needed in order to fully settle this issue.

Before concluding this section, let us briefly highlight the key technical novelty of our analysis. The primary challenge in establishing Theorems 1 and 2 lies in the development of suitable concentration results concerning the sample trajectory of interest. The classical concentration results for Markov chains (e.g., in [15]) do not readily address concentration of random variables in the form of
\[ \sum_{t=1}^{T} \left( f_t(s_t, a_t) - \mathbb{E}_{(s,a) \sim \mu_{\text{mix}}} [f_t(s, a)] \right), \] (12)
where $f_t : S \times A \rightarrow \mathbb{R}$ might depend on the historical sample trajectory $\{(s_i, a_i)\}_{i \leq t-1}$ (so not just $(s_t, a_t)$). To handle such complicated statistical dependency, we employ a decoupling argument (cf. Lemma 5) to reduce the concentration of (12) into the a number of $t_{\text{mix}} \log(T/\delta)$ martingale concentrations. Then we apply Freedman’s inequality [13, Theorem 3] to cope with each martingale concentration, thereby achieving sharp non-asymptotic concentration results for (12). The interested reader is referred to Step 2.4 in Appendix B-C for details. It is also worth emphasizing that the proof techniques developed in the current paper are drastically different from the ones used in [6] and [8]. In particular, the techniques introduced in [6] and [8] impose firm requirements that the data samples cover uniformly all state-action pairs, which are rarely satisfied under the partial-coverage scenario studied herein. What is more, minimax lower bounds related to the mixing time of a Markov chain in the RL context were previously rarely available. The analysis techniques developed here for establishing Theorem 3 might shed light on how to establish lower bounds for other settings that involve in-depth understanding of the mixing time.

V. RELATED WORKS

A. Offline RL and Pessimism

The principal of pessimism (or conservatism) in the face of uncertainty has recently been employed and studied extensively in offline RL (also called batch RL), e.g., [9], [10], [19], [21], [22], [23], [24], [25], [26], [27], [28], [29], [30], [31], [32], [33], [34], and [35]. Among these prior works, [10] studied offline RL for infinite-horizon MDPs when the offline data are i.i.d. samples drawn from some distribution $\mu$ satisfying the single policy concentrability condition. They showed that a model-based value iteration algorithm with LCB penalization achieves a sample complexity of $O(\frac{SC^*}{\mu(1-\gamma)^2}\varepsilon^2)$, which is comparable to our bound for Algorithm 1 (see (8)) and is worse than our bound for Algorithm 2 (see (11)) by a factor of $\frac{S}{t_{\text{mix}}(1-\gamma)^2}$ (ignoring the $o(\varepsilon^{-2})$ term and logarithm factors). Note that the setting considered in [10] is a special case of our setting by taking $t_{\text{mix}} = 1$. In addition, [9] proposed a pessimistic variant of the value iteration algorithm, which achieves appealing performance under the episodic linear MDP setting. Furthermore, the recent works [19], [20] proposed several pessimistic variants of RL algorithms for finite-horizon episodic MDPs. Focusing on offline RL with episodic data generated using some reference policy satisfying the single policy concentrability condition, these algorithms achieve a sample complexity of $O((H^3SC^*/\varepsilon^2)$.

B. Q-Learning

There are at least two basic forms of Q-learning: the synchronous version and the asynchronous counterpart. Synchronous Q-learning typically assumes access to a simulator that generates independent samples for all state-action pairs, and attempts to update all entries of the Q-function estimates simultaneously [4], [6], [38], [39], [40], [41], [42]. The current paper studies the asynchronous form of Q-learning, which naturally arises when the data is a Markovian trajectory induced by a behavior policy [2], [3], [4], [6], [7], [8], [43], [44], [45], [46]. However, most prior works focused on the case when the observed trajectory is able to cover all state-action pairs with sufficient frequency [4], [6], [7], [8], [38], [43]. For instance, the recent work [7] demonstrated that the sample complexity of asynchronous Q-learning is at most $O\left( \frac{t_{\text{mix}}}{\mu_{\text{mix}}(1-\gamma)^2} \right)$, which was subsequently sharpened by [6] to $O\left( \frac{t_{\text{mix}}}{\mu_{\text{mix}}(1-\gamma)^2} + \frac{t_{\text{mix}}}{\mu_{\text{mix}}(1-\gamma)^2} \right)$. It is also worth noting that some variants of model-free algorithms (e.g., the variant coupled with upper confidence bounds) have proven effective for online exploratory RL [13], [17], [47], [48], [49], [50], [51], [52], [53]; while online RL is beyond the scope of the current paper, the analysis framework therein based on the optimism principle shed light on our setting as well. In comparison to the model-based approach [54], [55], [56], [57], model-free algorithms like Q-learning often incur lower memory and computational complexities.

C. Variance Reduction

The idea of variance reduction first appeared in the stochastic optimization literature [18] and has been recently employed in RL to speed up various algorithms [8], [11], [12], [13], [20], [53], [58], [59], [60], [61], [62], [63], [64],
for all \( s, s' \in S \) and \( a \in A \). For any deterministic policy \( \pi \), we introduce two probability transition kernels \( P_\pi : S \times A \rightarrow \Delta(S) \) and \( P^\ast : S \times A \rightarrow \Delta(S \times A) \), defined in a way that
\[
P_\pi(s' | s) = P(s' | s, \pi(s)) \tag{14a}
\]
\[
P^\ast (s', a' | s, a) = \begin{cases} P(s' | s, a), & \text{if } a' = \pi(s') \\ 0, & \text{otherwise} \end{cases} \tag{14b}
\]
for any \( (s, a), (s', a') \in S \times A \). In addition, we define \( \rho^\ast \) to be a distribution on \( S \times A \) such that
\[
\rho^\ast(s, a) \begin{cases} \rho(s), & \text{if } a = \pi^\ast(s) \\ 0, & \text{otherwise} \end{cases} \tag{15}
\]
For any two vectors \( a = [a_i]_{i=1}^n \in \mathbb{R}^n \) and \( b = [b_i]_{i=1}^n \in \mathbb{R}^n \), we define the Hadamard product \( a \odot b = [a_i b_i]_{i=1}^n \), as well as the concise notation \( a^2 = a \odot a \). We also use \( a \leq b \) (resp. \( a \geq b \)) to denote \( a_i \leq b_i \) (resp. \( a_i \geq b_i \)) for all \( i \in [n] \). Moreover, for two vectors \( a = [a_1, \ldots, a_n] \) and \( b = [b_1, \ldots, b_n] \), we abuse the notation by letting
\[
\langle a, b \rangle = \sum_{i=1}^n a_i b_i
\]
even when \( a \) is a row vector and \( b \) is a column vector. For any \( s \in S \), \( a \in A \) and any vector \( V \in \mathbb{R}^S \), we define and denote
\[
\text{Var}_{s,a}(V) := \text{Var}_{s \sim P^\ast(\cdot | s, a)}(V(s)) = P_{s,a}(V^2) - (P_{s,a}V)^2.
\]
We let \( f(n) \leq g(n) \) or \( f(n) = O(g(n)) \) to denote \( |f(n)| \leq C g(n) \) for some constant \( C > 0 \) when \( n \) is sufficiently large; we use \( f(n) \leq g(n) \) to indicate that \( f(n) \geq C g(n) \) for some constant \( C > 0 \) when \( n \) is sufficiently large; and we let \( f(n) = g(n) \) represent the condition that \( f(n) \leq g(n) \) and \( f(n) \geq g(n) \) hold simultaneously. Throughout this paper, we define \( 0/0 = 0 \). For any sequence \( \{a_i \}_{i=1}^n \) and two integers \( m_1 \) and \( m_2 \), we define
\[
\sum_{i=m_1}^{m_2} a_i = \sum_{\substack{i=m_1 \\text{to} \\text{max}\{n, m_1, m_2\}}} a_i
\]
if \( \max\{n, m_1\} \leq \min\{n_2, m_2\} \), and 0 otherwise.

### APPENDIX B

**Analysis for Q-Learning With LCB Penalization (Theorem 1)**

In this section, we present the proof of Theorem 1, which consists of several steps to be detailed below.

#### A. Preliminary Facts and Additional Notation

Before proceeding, we first introduce the following quantities regarding the learning rates:
\[
\eta_0^t := \prod_{j=1}^t (1 - \eta_j) \tag{16a}
\]
and
\[
\eta_i^t := \begin{cases} \eta_i \prod_{j=i+1}^t (1 - \eta_j), & \text{if } t > i \\ \eta_i, & \text{if } t = i \\ 0, & \text{if } t < i \end{cases} \tag{16b}
\]
where we recall our choice $n_j = (H+1)/(H+j)$. We make note of the following results that have been established in prior works (e.g., [17, Lemma 4.1] and [13, Lemma 1]).

**Lemma 1:** The learning rates satisfy the following properties.

1. For any integer $t \geq 1$, $\sum_{i=1}^{t} \eta_i^t = 1$ and $\eta_0^t = 0$.
2. For any integer $t \geq 1$ and any $1/2 \leq a \leq 1$,
   $$\frac{1}{t^a} \leq \sum_{i=1}^{t} \frac{1}{t^a \eta_i^t} \leq \frac{2}{t^a}.$$  
3. For any integer $t \geq 1$,
   $$\max_{i \in [t]} \eta_i^t \leq \frac{2H}{t} \quad \text{and} \quad \sum_{i=1}^{t} (\eta_i^t)^2 \leq \frac{2H}{t}.$$  
4. For any integer $i \geq 1$,
   $$\sum_{i=1}^{\infty} \eta_i^t = 1 + \frac{1}{H}.$$  

For any iteration $t \leq T$, we remind the reader that $n_t$ represents the number of times $(s,a)$ has been visited prior to iteration $t$ (see Algorithm 1). For notational simplicity, let $n = n_t(s,a)$ when it is clear from the context, and suppose that $(s,a)$ has been visited during the iterations $k_1 < \cdots < k_n < t$. We also find it convenient to define the (deterministic) policy estimate $\pi_t : S \to A$ recursively as follows:

$$\pi_t(s) := \arg \max_{a \in A} Q_t(s_{t-1}, a)$$

(17a)

if $s = s_{t-1}$ and $V_t(s) > V_{t-1}(s)$, and

$$\pi_t(s) := \pi_{t-1}(s)$$

(17b)

otherwise. If there are multiple $a \in A$ that maximize $Q_t(s_{t-1}, a)$, we can pick any of these actions.

The following lemma provides a useful upper bound on $Q^* - Q_t$, and in the meantime, justifies that the value function estimate $V_t$ is always a pessimistic view of $V^{\pi_t}$ (and hence $V^*$). The proof of this lemma is postponed to Appendix C-A.

**Lemma 2:** With probability exceeding $1 - \delta$, for all $s \in S$ and $t \in [T]$, it holds that

$$Q^*(s, \pi^*(s)) - Q_t(s, \pi^*(s)) \leq \gamma \sum_{i=1}^{n} \eta_i^t P_{s,\pi^*(s)}(V^* - V_{k_i}) + \beta_n(s, \pi^*(s)),$$

where $n = n_t(s, \pi^*(s))$ and we define

$$\beta_n(s, \pi^*(s)) \equiv \beta_n := 3C \sqrt{\frac{Ht}{n(1-\gamma)^2}}.$$  
in addition, we also have

$$V_t(s) \leq V^{\pi^*_t}(s) \leq V^*(s), \quad \forall s \in S.$$  

Next, let us define two disjoint sets of state-action pairs, divided based on the associated occupancy probability induced by the behavior policy:

$$T := \left\{ (s, \pi^*(s)) | s \in S, \mu_b(s, \pi^*(s)) \geq \frac{\delta}{ST} \right\},$$  

(18a)

$$T^c := \left\{ (s, \pi^*(s)) | s \in S, \mu_b(s, \pi^*(s)) < \frac{\delta}{ST} \right\}.$$  

(18b)

It turns out that the state-action pairs in $T^c$ are rarely visited, as formalized by the following lemma. The proof is deferred to Appendix C-B.

**Lemma 3:** With probability exceeding $1 - \delta$, we have

$$T^c \cap \{(s_t, a_t)\}^T_{t=t_{min}(\delta)} = \emptyset.$$  

**B. Step 1: Error Decomposition**

Before proceeding, let us introduce several quantities that will play an important role in our analysis in (19), shown at the bottom of the next page, where we recall the definition of $T$ in (18).

Let us begin with the following basic inequality:

$$V^*(\rho) - V^{\tilde\pi}(\rho) = \langle \rho, V^* - V^{\tilde\pi} \rangle^{(i)} \leq \langle \rho, V^* - V_T \rangle$$

\[ \leq \frac{1}{T} \sum_{t=1}^{T} \langle \rho, V^* - V_t \rangle \leq \frac{1}{T} \alpha_0. \]  

(20)

Here, (i) holds true according to Lemma 2; (ii) follows from the monotonicity of $V_t$ in $t$ (by construction); and (iii) follows simply from the definition of $\alpha_0$. We then turn attention to bounding $\alpha_0$, towards which we observe (21), shown at the bottom of the next page. In (21) the first identity holds since $V^*(s) = Q^*(s, \pi^*(s))$ and $0 \leq V^*(s) - V_t(s) \leq 1/(1-\gamma)$ for all $s \in S$, the second line relies on the fact that $V_t(s) \geq \max_a Q_t(s, a)$, which is the last line invokes Lemma 2. With probability exceeding $1 - \delta$, the first term $\zeta$ can be upper bounded by (22), shown at the bottom of page 7196, where we remind the reader of our notation $\rho_{\pi^*}$ in (15). In (22), (i) is valid (i.e., $\rho(s_{t_i}, a_{t_i})/\mu_b(s, a)$ is well defined for $t \geq t_{mix}(\delta)$) due to Lemma 3; (ii) holds by grouping the terms in the previous line; and (iii) utilizes Lemma 1 and the property that $V^* \geq V_t$ (cf. Lemma 2). Therefore, we arrive at

$$\alpha_0 \leq \sum_{t=1}^{t_{min}(\delta)} \langle \rho, V^* - V_t \rangle + \zeta + \theta_0$$

$$\leq \sum_{t=1}^{t_{min}(\delta)} \langle \rho, V^* - V_t \rangle + \alpha_1 + \psi_0 + \phi_0$$

$$+ \gamma \left(1 + \frac{1}{H}\right) \langle +\theta_0\rho_{\pi^*}, V^* - V_t \rangle$$

$$= \alpha_1 + \xi_0 + \theta_0 + \psi_0 + \phi_0,$$

where we have used the definition of $\xi_0$. Repeat the same argument to reach

$$\alpha_j \leq \alpha_{j+1} + \xi_j + \theta_j + \psi_j + \phi_j.$$
for all \( j \geq 1 \). This in turn allows us to conclude that
\[
\alpha_0 \leq \limsup_{j \to \infty} \alpha_j + \sum_{j=0}^{\infty} \xi_j + \sum_{j=0}^{\infty} \theta_j + \sum_{j=0}^{\infty} \psi_j + \sum_{j=0}^{\infty} \phi_j. \tag{23}
\]
We will then bound the terms \( \alpha, \xi, \theta, \psi \) and \( \phi \) separately in the subsequent steps. Before continuing, we make note of a useful result.

**Lemma 4:** Recall that \( H = \left\lceil \frac{4}{1-\gamma} \log \frac{ST^4}{\delta} \right\rceil \) for some \( 0 < \delta < 1 \). For any vector with non-negative entries \( V \in \mathbb{R}^d \), we have
\[
\sum_{j=0}^{\infty} \left( \frac{1}{1-\gamma} \right)^j \left\langle d^*, V \right\rangle + \frac{\delta}{ST^4(1-\gamma)} \| V \|_{\infty}. \tag{24}
\]
**Proof:** See Appendix C.C.

**C. Step 2: Bounding Each Term in (23)**

1) **Step 2.1: Bounding \( \alpha \):** It is first observed that
\[
\alpha = \limsup_{j \to \infty} \left[ \gamma \left( 1 + \frac{1}{H} \right)^{3j} \sum_{t=1}^{T} \left\langle \rho \left( P_{\pi^*} \right)^j, V^* - V_t \right\rangle \right].
\]
Here, (i) is valid since \( \rho \left( P_{\pi^*} \right)^j \) is a probability distribution over \( S \) and \( 0 \leq V^* - V_t \leq 1/(1-\gamma) \) holds for all \( 1 \leq t \leq T \); (ii) holds since
\[
\gamma \left( 1 + \frac{1}{H} \right)^{3j} \leq \gamma \left( 1 + \frac{1-\gamma}{4} \right)^{2} < 1 \tag{25}
\]
for all \( \gamma < 1 \).

\[
\alpha_j := \gamma \left( 1 + \frac{1}{H} \right)^{3j} \sum_{t=1}^{T} \left\langle \rho \left( P_{\pi^*} \right)^j, V^* - V_t \right\rangle, \tag{19a}
\]
\[
\theta_j := \gamma \left( 1 + \frac{1}{H} \right)^{3j} \sum_{t=1}^{T} \sum_{s \in S} \left[ \rho \left( P_{\pi^*} \right)^j \right] \left( s, \pi^*(s) \right) \min \left\{ \beta_{n_t(s, \pi^*(s))} \left( s, \pi^*(s) \right), \frac{1}{1-\gamma} \right\}, \tag{19b}
\]
\[
\xi_j := \gamma \left( 1 + \frac{1}{H} \right)^{3j} \sum_{t=1}^{T} \left\langle \rho \left( P_{\pi^*} \right)^j, V^* - V_t \right\rangle + \gamma \left( 1 + \frac{1}{H} \right)^{3j+1} \left\langle \rho \left( P_{\pi^*} \right)^{j+1}, V^* - V_0 \right\rangle, \tag{19c}
\]
\[
\psi_j := \gamma \left( 1 + \frac{1}{H} \right)^{3j} \sum_{t=1}^{T} \left[ \sum_{s \in S, a \in A} \rho^*(P_{\pi^*})^j \left( s, a \right) \sum_{i=1}^{n_t(s,a)} \eta_i^n(s,a) P_{s,a} \left( V^* - V_{k(s,a)} \right) \right. \tag{19d}
\]
\[
- \left( 1 + \frac{1}{H} \right) \left[ \rho^*(P_{\pi^*})^j \left( s_t, a_t \right) \mu_b(s_t, a_t) \sum_{i=1}^{n_t(s_t,a_t)} \eta_i^n(s_t,a_t) P_{s_t,a_t} \left( V^* - V_{k(s_t,a_t)} \right) \right], \right.
\]
\[
\phi_j := \gamma^{j+1} \left( 1 + \frac{1}{H} \right)^{3j+2} \sum_{t=0}^{T} \mathbb{I}(s_t, a_t) \in I \left[ \sum_{s \in S, a \in A} \rho^*(P_{\pi^*})^j \left( s, a \right) P_{s,a} \left( V^* - V_t \right) \right. \tag{19e}
\]
\[
- \left( 1 + \frac{1}{H} \right) \sum_{s \in S, a \in A} \rho^*(P_{\pi^*})^j \left( s, a \right) P_{s,a} \left( V^* - V_t \right) \right].
\]

\[
\alpha_0 = \sum_{t=1}^{T} \left\langle \rho \left( V^* - V_t \right) + \sum_{t=1}^{T} \sum_{s \in S} \rho \left( s \right) \min \left\{ Q^* \left( s, \pi^*(s) \right) - V_t(s), \frac{1}{1-\gamma} \right\} \right. \tag{21}
\]
\[
\leq \sum_{t=1}^{T} \left\langle \rho \left( V^* - V_t \right) + \sum_{s \in S} \rho \left( s \right) \min \left\{ Q^* \left( s, \pi^*(s) \right) - Q_t \left( s, \pi^*(s) \right), \frac{1}{1-\gamma} \right\} \right. \tag{21}
\]
\[
\leq \sum_{t=1}^{T} \left\langle \rho \left( V^* - V_t \right) + \gamma \sum_{t=1}^{T} \sum_{s \in S} \rho \left( s \right) \sum_{i=1}^{n_t(s, \pi^*(s))} \eta_i^n(s, \pi^*(s)) P_{s, \pi^*(s)} \left( V^* - V_{k(s)} \right) \right. \tag{21}
\]
\[
+ \sum_{t=1}^{T} \sum_{s \in S} \rho \left( s \right) \min \left\{ \beta_{n_t(s, \pi^*(s))} \left( s, \pi^*(s) \right), \frac{1}{1-\gamma} \right\}. \right. \tag{21}
\]
2) **Step 2.2: Bounding ξ:** By utilizing (24) and (25), we can demonstrate that

\[
ξ = \sum_{t=1}^{t_{\text{mix}}(δ)} \left\{ \sum_{j=0}^{\infty} \left[ \gamma \left( 1 + \frac{1}{H} \right)^3 \right] \langle ρP_{\pi^*}, V^* - V_t \rangle \right. \\
+ \sum_{j=0}^{\infty} \left[ γ \left( 1 + \frac{1}{H} \right)^3 \right] \langle ρ(\pi^*)^{j+1}, V^* - V_0 \rangle \\
\leq \frac{1}{1 - γ} \sum_{t=0}^{t_{\text{mix}}(δ)} \langle d^*_f, V^* - V_t \rangle + \frac{1}{ST^4(1 - γ)} t_{\text{mix}}(δ) + 1
\]

Here, the second line holds due to (24) and the basic fact 0 ≤ V^*(s) - V_t(s) ≤ 1/γ, the penultimate line makes use of the basic property of the operator ||V^* - V_t|| ≤ 1/γ once again, whereas the last line holds since t_{\text{mix}}(δ) ≤ t_{\text{mix}} log 1/δ.

3) **Step 2.3: Bounding θ:** When it comes to θ, we can deduce that where we define, for each s ∈ S,

\[
t_{\text{burn-in}}(s) := C_{\text{burn-in}} \frac{t_{\text{mix}}(s)}{\mu_b(s, π⋆(s))} \log \left( \frac{ST}{δ} \right)
\]

for some sufficiently large constant C_{\text{burn-in}} > 0. In (26), shown at the bottom of the next page, (i) relies on (24); (ii) utilizes [8, Lemma 8]; (iii) follows from the fact that

\[
\frac{1}{\sqrt{T}} \leq 1 + \int_1^T \frac{1}{\sqrt{x}} dx = 1 + 2\left( \sqrt{T} - 1 \right) \leq 2\sqrt{T}; \tag{27}
\]

(iv) uses Assumption 2; and (v) invokes the Cauchy-Schwarz inequality and the fact that ∑_a d^*_f(s, π⋆(s)) = 1.

4) **Step 2.4: Bounding ψ:** Recall the definition of ψ_j in (19). In order to bound ψ, we make the observation (28), shown at the bottom of the next page. In (28), d(·, ·) is defined such that

\[
d(s, a) := \sum_{j=0}^{\infty} \gamma \left[ γ \left( 1 + \frac{1}{H} \right)^3 \right] [ρ(π^*)^j](s, a)
\]

for any (s, a) ∈ S × A. For any t_{\text{mix}}(δ) ≤ t ≤ T and any (s, a) ∈ I, let us define

\[
f_t(s, a) = \frac{d(s, a)}{μ_b(s, a)} ∑_{i=1}^{n_t(s, a)} η_i n_t(s, a) P_{s, a} (V^* - V_{ki(s, a)})
\]

allowing us to rewrite

\[
ψ = ∑_{t=t_{\text{mix}}(δ)}^{T} \left\{ \mathbb{E}_{(s, a) ∼ μ_b}[f_t(s, a)] - \left( 1 + \frac{1}{H} \right)f_t(s_t, a_t) \right\}.
\tag{29}
\]

Let us take a moment to look at some properties of f_t. It is straightforward to check that

1) when a ≠ π⋆(s), one has f_t(s, a) = 0;
2) f_t(s, a) is monotonically decreasing in t.

The latter property follows from the non-decreasing property of V_t in t (by construction), and that η_i n_t(s, a) is decreasing in t, as well as ∑_i n_t(s, a) η_i n_t(s, a) = 1 (cf. Lemma 1). On the other hand, when a = π⋆(s) and (s, a) ∈ I, we can invoke (24) to arrive at

\[
d(s, π⋆(s)) \leq \frac{1}{1 - γ} d^*_ρ(s) + \frac{δ}{ST^4(1 - γ)}
\tag{30}
\]
and consequently,
\[
\begin{align*}
    f_t(s,a) & \leq \left\{ \frac{1}{1-\gamma} \frac{d^*_\rho(s,a)}{\mu_b(s,a)} + \frac{\delta}{ST^4} \frac{1}{1-\gamma} \frac{1}{\mu_b(s,a)} \right\} \\
    & \quad \cdot \sum_{i=1}^{n_t(s,a)} \eta_i^{n_t(s,a)} P_{s,a} (V^* - V_{k_i(s,a)}) \\
    & \leq \frac{1}{1-\gamma} \frac{d^*_\rho(s,a)}{\mu_b(s,a)} + \frac{\delta}{ST^4} \frac{1}{1-\gamma} \frac{1}{\mu_b(s,a)} \\
    & \leq \frac{c_{10} C^*}{(1-\gamma)^2} := C_f. 
\end{align*}
\]

for some constant \(c_{10} \geq 1\). Here, the second line follows from Assumption 2, the properties that \(\sum_{i=1}^{n_t(s,a)} \eta_i^{n_t(s,a)} = 1\), \(0 \leq V^*(s) - V_t(s) \leq 1/(1-\gamma)\) for all \(0 \leq t \leq T\); the third line is valid since \(\mu_b(s,\pi^*(s)) \geq \delta/(ST)\) when \((s,\pi^*(s)) \in I\).

We now proceed to bound (29). It is worth noting that both \(f_t(s,a)\) and \((s_t,a_t)\) depend on \(s_0, a_0, s_1, \ldots, s_{t-1}, a_{t-1}\). To handle such statistical dependency, we define
\[
K := \frac{T}{\tau} \quad \text{where} \quad \tau := t_{\text{mix}}(\delta/T^2) \lesssim t_{\text{mix}} \log \frac{T}{\delta}.
\]

Armed with this notation, one can decompose \(\psi\) as shown in (32), shown at the bottom of the next page. In what follows, we bound \(\kappa_1, \kappa_2, \kappa_3\) and \(\kappa_4\) respectively.

- The term \(\kappa_4\) can be easily bounded using (31) as follows
\[
\kappa_4 \leq \left( \sum_{t=t_{\text{mix}}(\delta)}^{T} + \sum_{t=K+1}^{T} \right) \mathbb{E}[f_t(s,a)]
\leq 2\tau C_f \times C^* t_{\text{mix}} \log \left( \frac{T}{\delta} \right).
\]

- With regards to \(\kappa_3\), we make the observation that
\[
\kappa_3 = \left( 1 + \frac{1}{H} \right) \sum_{t=t+1}^{T} \sum_{s,a \in A} [f_t(s,a) - f_t(s,a)]
\leq \left( 1 + \frac{1}{H} \right) \sum_{t=t+1}^{T} \sum_{s,a \in A} [f_t(s,a) - f_t(s,a)]
\]

\[
\begin{align*}
\theta &= \sum_{j=0}^{\infty} \left[ \gamma \left( 1 + \frac{1}{H} \right) \right]^j \sum_{t=1}^{T} \sum_{s \in S} \rho(P_{s,a}) (s) \min \left\{ \beta_{n_t(s,a)}, \frac{1}{1-\gamma} \right\} \\
&= \sum_{t=1}^{T} \sum_{s \in S} \left[ \gamma \left( 1 + \frac{1}{H} \right) \right] \sum_{s \in S} \rho(P_{s,a}) (s) \min \left\{ \beta_{n_t(s,a)}, \frac{1}{1-\gamma} \right\} \\
&\leq \sum_{s \in S} \frac{d^*_\rho(s)}{1-\gamma} + \sum_{s \in S} \frac{d^*_\rho(s)}{1-\gamma} \sqrt{\frac{H_t}{n_t(s,\pi^*(s))} \left( 1 - \gamma \right)^4} + \frac{1}{T^3 (1-\gamma)^2} \\
&\leq \frac{C^* T\text{mix}}{(1-\gamma)^2} + \sqrt{\frac{C^* T\text{mix}}{(1-\gamma)^2}} + \frac{C^* T\text{mix}^2}{(1-\gamma)^2}, 
\end{align*}
\]

\[
\psi = \sum_{j=0}^{\infty} \left[ \gamma \left( 1 + \frac{1}{H} \right) \right]^j \sum_{t=t_{\text{mix}}(\delta)}^{T} \sum_{s \in S, a \in A} \rho_{\pi^*}(P_{s,a}^{\pi^*}) (s, a) \sum_{i=1}^{n_t(s,a)} \eta_i^{n_t(s,a)} P_{s,a} (V^* - V_{k_i(s,a)}) \\
- \left( 1 + \frac{1}{H} \right) \sum_{s \in S, a \in A} \frac{d^*_\rho(s)}{1-\gamma} \sum_{i=1}^{n_t(s,a)} \eta_i^{n_t(s,a)} P_{s,a} (V^* - V_{k_i(s,a)}) \\
- \left( 1 + \frac{1}{H} \right) \sum_{s \in S, a \in A} \frac{d^*_\rho(s)}{1-\gamma} \sum_{i=1}^{n_t(s,a)} \eta_i^{n_t(s,a)} P_{s,a} (V^* - V_{k_i(s,a)}).
\]
Similarly, $\kappa_2$ can be bounded by
\[
\kappa_2 = \sum_{t=\tau+1}^{K\tau} \left\{ \mathbb{E}_{(s,a)\sim \mu_b} \left[ f_t(s,a) \right] - \mathbb{E}_{(s,a)\sim \mu_b} \left[ f_{t-\tau}(s,a) \right] \right\}
\]
\[
= \sum_{t=(K-1)\tau+1}^{K\tau} \mathbb{E}_{(s,a)\sim \mu_b} \left[ f_t(s,a) \right] - \sum_{t=1}^{\tau} \mathbb{E}_{(s,a)\sim \mu_b} \left[ f_t(s,a) \right]
\]
\[
\leq \tau C_f \approx \frac{C^* S t_{\text{mix}}}{(1-\gamma)^2} \log \left( \frac{T}{\delta} \right).
\]

Finally, we turn attention to bounding $\kappa_1$. For each $1 \leq i \leq \tau$, we will bound
\[
\xi_i := \sum_{k=1}^{K-1} \left\{ \mathbb{E}_{(s,a)\sim \mu_b} \left[ f_{(k-1)\tau+i}(s,a) \right] - \left( 1 + \frac{1}{H} \right) f_{(k-1)\tau+i}(s_k, a_k) \right\}
\]
with probability exceeding $1 - \delta/T$. Recognizing the property (33c), we are ready to use the Freedman

\[
\psi = \sum_{t=1}^{\tau} \sum_{k=1}^{K-1} \left\{ \mathbb{E}_{(s,a)\sim \mu_b} \left[ f_{k\tau+t}(s,a) \right] - \left( 1 + \frac{1}{H} \right) f_{k\tau+t}(s_k, a_k) \right\}
\]
\[
+ \left( \sum_{t=t_{\text{mix}}(\delta)} + \sum_{t=K\tau+1}^{\tau} \right) \left\{ \mathbb{E}_{(s,a)\sim \mu_b} \left[ f_t(s,a) \right] - \left( 1 + \frac{1}{H} \right) f_t(s_t, a_t) \right\}
\]
\[
= \sum_{t=1}^{\tau} \sum_{k=1}^{K-1} \left\{ \mathbb{E}_{(s,a)\sim \mu_b} \left[ f_{(k-1)\tau+i}(s,a) \right] - \left( 1 + \frac{1}{H} \right) f_{(k-1)\tau+i}(s_k, a_k) \right\}
\]
\[
= \xi_1
\]
\[
+ \sum_{i=1}^{\tau} \sum_{k=1}^{K-1} \left\{ \mathbb{E}_{(s,a)\sim \mu_b} \left[ f_{k\tau+i}(s,a) \right] - \mathbb{E}_{(s,a)\sim \mu_b} \left[ f_{(k-1)\tau+i}(s,a) \right] \right\}
\]
\[
= \xi_2
\]
\[
+ \left( 1 + \frac{1}{H} \right) \sum_{i=1}^{\tau} \sum_{k=1}^{K-1} \left\{ f_{(k-1)\tau+i}(s_k, a_k) - f_{k\tau+i}(s_k, a_k) \right\}
\]
\[
= \xi_3
\]
\[
+ \left( \sum_{t=t_{\text{mix}}(\delta)} + \sum_{t=K\tau+1}^{\tau} \right) \left\{ \mathbb{E}_{(s,a)\sim \mu_b} \left[ f_t(s,a) \right] - \left( 1 + \frac{1}{H} \right) f_t(s_t, a_t) \right\}
\]
\[
= \xi_4.
\]

respectively. We need the following lemma to decouple the complicated statistical dependency.

\textbf{Lemma 5:} One can construct an auxiliary set of random variables \{ $(s_k^i, a_k^j) : 1 \leq k \leq K - 1$ \} satisfying
\[
\{ (s_k^i, a_k^j) : 1 \leq k \leq K - 1 \} \overset{i.i.d.}{\sim} \mu_b,
\]
\[
P\left\{ (s_k^i, a_k^j) = (s_{k\tau+i}, a_{k\tau+i}) \text{ for all } 1 \leq k \leq K - 1 \right\}
\]
\[
\geq 1 - \delta/T,
\]
and
\[
(s_k^i, a_k^j) \text{ is independent of } \{ (s_t, a_t) : 0 \leq t \leq (k-1)\tau + i \}.
\]

\textbf{Proof:} See Appendix C-D.

With the above set of auxiliary random variables \{ $(s_k^i, a_k^j) : 1 \leq k \leq K - 1$ \} in place, one can obtain

The final expression involves the Freedman's inequality applied to the constructed set of random variables.

Authorized licensed use limited to the terms of the applicable license agreement with IEEE. Restrictions apply.
inequality (cf. [13, Theorem 3]) to bound \( \xi_i \). Introduce the random variable

\[
X_k = f_{(k-1)\tau+i}(s_k, a_k) - \mathbb{E}_{(s,a)\sim \mu_k}[f_{(k-1)\tau+i}(s,a)],
\]

and define a filtration \( \mathcal{F}_0 \subset \mathcal{F}_1 \subset \cdots \subset \mathcal{F}_{K-1} \) with

\[
\mathcal{F}_{k-1} = \sigma \left\{ \{(s_k, a_k)\}_{k=1}^{K-1}, \{(s_t, a_t)\}_{t=0}^{(k-1)\tau+i} \right\}
\]

for \( 1 \leq k \leq K-1 \). It is straightforward to verify that

\[
|X_k| \leq R := C_f, \quad \mathbb{E}[X_k | \mathcal{F}_{k-1}] = 0
\]

for all \( 1 \leq k \leq K-1 \), and

\[
W := \sum_{k=1}^{K-1} \mathbb{E}[X_k^2 | \mathcal{F}_{k-1}] \leq \sum_{k=1}^{K-1} \mathbb{E} \left[ f_{(k-1)\tau+i}(s_k, a_k)^2 | \mathcal{F}_{k-1} \right] \leq C_f \sum_{k=1}^{K-1} \mathbb{E} \left[ f_{(k-1)\tau+i}(s_k, a_k) | \mathcal{F}_{k-1} \right] = C_f \sum_{k=1}^{K-1} \mathbb{E} \left[ f_{(k-1)\tau+i}(s,a) \right] \leq C_f^2 K.
\]

Invoke the Freedman inequality in [13, Theorem 3] to show that for any integer \( m \geq 1 \),

\[
\left| \sum_{k=1}^{K-1} X_k \right| \leq \sqrt{8 \max \left\{ W, \frac{C_f^2 K}{2^m} \right\} \log \frac{2Tm}{\delta} + \frac{4}{3} \frac{R \log T}{\delta}} \leq \sqrt{8W \log \frac{2Tm}{\delta} + \frac{8C_f^2 K}{2^m} \frac{2Tm}{\delta}} + \frac{4}{3} C_f \log \frac{2Tm}{\delta} \leq \frac{1}{2HC_f} W + 4HC_f \log \frac{2Tm}{\delta} + \frac{4}{3} C_f \log \frac{2Tm}{\delta} \leq \frac{1}{2HC_f} \sum_{k=1}^{K-1} \mathbb{E}_{(s,a)\sim \mu_k} \left[ f_{(k-1)\tau+i}(s,a) \right] + O \left( HC_f \log \frac{T}{\delta} \right)
\]

holds with probability exceeding \( 1 - \delta/T \). Here, the penultimate line relies on the AM-GM inequality, whereas the last line holds by using (35) and taking \( m \propto \log K \propto \log T \lesssim T \). Consequently, we see that with probability exceeding \( 1 - \delta/T \),

\[
\xi_i = - \left( 1 + \frac{1}{H} \right)^{K-1} \sum_{k=1}^{K-1} X_k - \frac{1}{H} \sum_{k=1}^{K-1} \mathbb{E}_{(s,a)\sim \mu_k} \left[ f_{(k-1)\tau+i}(s,a) \right]
\]

\[
\leq 2 \left| \sum_{k=1}^{K-1} X_k \right| - \frac{1}{H} \sum_{k=1}^{K-1} \mathbb{E}_{(s,a)\sim \mu_k} \left[ f_{(k-1)\tau+i}(s,a) \right] \leq HC_f \log \frac{T}{\delta} \lesssim \frac{C^* \delta^2}{(1-\gamma)^3} \log \frac{T}{\delta}.
\]

As a result, with probability exceeding \( 1 - \delta \) we can guarantee that

\[
\kappa_1 \lesssim \sum_{i=1}^{\tau} \xi_i \lesssim \frac{C^* \delta^2}{(1-\gamma)^3} \log \left( \frac{T}{\delta} \right) \lesssim \frac{C^* t_{mix}^2}{(1-\gamma)^3} \log^2 \left( \frac{T}{\delta} \right).
\]

The above bounds taken collectively allow us to conclude that

\[
\psi \leq \kappa_1 + \kappa_2 + \kappa_3 + \kappa_4 \lesssim \frac{C^* t_{mix}^2}{(1-\gamma)^3} \log^2 \left( \frac{T}{\delta} \right) + \frac{C^* S t_{mix}}{(1-\gamma)^2} \log \left( \frac{T}{\delta} \right).
\]

5) Step 2.5: Bounding \( \phi \): By replacing \( f_t(s,a) \) in Step 4 with

\[
g_t(s,a) = P_{s,a} (V^* - V_t),
\]

we can employ an analogous argument to show that \( \phi \) admits the same bound as \( \psi \), namely,

\[
\phi \lesssim \frac{C^* t_{mix}^2}{(1-\gamma)^3} \log^2 \left( \frac{T}{\delta} \right) + \frac{C^* S t_{mix}}{(1-\gamma)^2} \log \left( \frac{T}{\delta} \right).
\]

We omit this part for the sake of brevity.

D. Step 3: Putting All Pieces Together

To finish up, taking the bounds on \( \alpha, \theta, \psi \) and \( \phi \) collectively gives

\[
\alpha_0 \leq \alpha + \xi + \theta + \psi + \phi \lesssim \frac{C^* S t_{mix}}{(1-\gamma)^2} + \frac{C^* S t_{mix}}{(1-\gamma)^3} + \frac{C^* t_{mix}^2}{(1-\gamma)^3} \log^2 \left( \frac{T}{\delta} \right) + \frac{C^* S t_{mix}}{(1-\gamma)^2} \log \left( \frac{T}{\delta} \right) \lesssim \frac{C^* S t_{mix}^2}{(1-\gamma)^3} + \frac{C^* S t_{mix}}{(1-\gamma)^2} + \frac{C^* t_{mix}^2}{(1-\gamma)^3} \log^2 \left( \frac{T}{\delta} \right).
\]

Consequently, we can invoke (20) to conclude that

\[
V^*(\rho) - V^\pi(\rho) \leq \frac{\alpha_0}{T} \lesssim \sqrt{\frac{C^* S t_{mix}^2}{T(1-\gamma)^3} + \frac{C^* S t_{mix}}{T(1-\gamma)^2} + \frac{C^* t_{mix}^2}{T(1-\gamma)^3}}.
\]

APPENDIX C

AUXILIARY LEMMAS FOR THEOREM 1

A. Proof of Lemma 2

Consider any given pair \((s,a)\in S\times A\). For notational simplicity, we write \( n_t(s,a) \), the total number of times that \((s,a)\) has been visited prior to time \( t \). We also set \( k_0 = -1 \), and let

\[
k_i := \min \left\{ \{0 \leq k < T : k > k_{i-1}, (s_k, a_k) = (s, a)\}, \right\}
\]

(36)
for each $1 \leq i \leq T$. Clearly, each $k_i$ is a stopping time. In view of the update rule in Algorithm 1, we have

$$Q_t(s, a) = \sum_{i=1}^{n} \eta_i^n \{ r(s, a) + \gamma V_{k_i}(s_{k_i+1}) - b_i(s, a) \},$$

which together with the Bellman optimality equation $Q^* = r + \gamma PV^*$ gives

$$(Q^* - Q_t)(s, a) = r(s, a) + \gamma P_{s,a}V^* - \sum_{i=1}^{n} \eta_i^n \{ r(s, a) + \gamma V_{k_i}(s_{k_i+1}) - b_i(s, a) \}$$

$$= \gamma P_{s,a}V^* - \sum_{i=1}^{n} \eta_i^n \{ \gamma V_{k_i}(s_{k_i+1}) - b_i(s, a) \}$$

$$= \sum_{i=1}^{n} \eta_i^n \gamma P_{s,a} (V^* - V_{k_i})$$

$$+ \sum_{i=1}^{n} \eta_i^n \gamma ((P - P_{k_i})V_{k_i})(s, a)$$

$$+ \sum_{i=1}^{n} \eta_i^n b_i(s, a), \tag{37}$$

where the last two lines are valid since $\sum_{i=1}^{n} \eta_i^n = 1$ (cf. Lemma 1).

From now on we only focus on the case where $a = \pi^*(s)$. Define $F_t$ to be the $\sigma$-field generated by $\{(s_i, a_i)\}_{i=0}^{k_i}$. It is straightforward to check that for any $1 \leq \tau \leq T,$

$$\{1_{k_i < \tau T}((P - P_{k_i})V_{k_i})(s, \pi^*(s))\}_{i=1}^{\tau}$$

is a martingale difference sequence with respect to $\{F_t\}_{t \geq 0}$. Then, we can invoke the Azuma-Hoeffding inequality together with the basic bound $\|V_{k_i}\|_\infty \leq \frac{1}{\tau - \gamma}$ to show that for any fixed $s \in S$ and $\tau \in [T],$

$$\sum_{i=1}^{\tau} 1_{k_i < \tau T} \eta_i^n ((P - P_{k_i})V_{k_i})(s, \pi^*(s))$$

$$\lesssim \frac{1}{1 - \gamma} \sqrt{\sum_{i=1}^{\tau} (\eta_i^n)^2 \log \frac{ST}{\delta} \lesssim \sqrt{\frac{H}{\tau (1 - \gamma)^2} \log \frac{ST}{\delta}}$$

holds with probability exceeding $1 - \delta/(ST)$. Here, the last line utilizes Lemma 1. Taking the union bound over $\tau \leq T$ allows us to replace $\tau$ with $n = n_t(s, a)$ in the above inequality, namely, for any fixed $s \in S$ and $a \in A$, with probability exceeding $1 - \delta/S$ we have

$$\sum_{i=1}^{n} \eta_i^n ((P - P_{k_i})V_{k_i})(s, \pi^*(s)) \lesssim \sqrt{\frac{Ht}{n (1 - \gamma)^2}} \tag{38}$$

holds for all $n = n_t(s, \pi^*(s))$ with $1 \leq t \leq T$. In view of Lemma 1, for any $s \in S$ and $a \in A$ we know that

$$C_b \sqrt{\frac{Ht}{n_t(s, a)(1 - \gamma)^2}} \leq \sum_{i=1}^{n_t(s, a)} \eta_i^{n_t(s, a)} b_i(s, a)$$

$$\leq 2C_b \sqrt{\frac{Ht}{n_t(s, a)(1 - \gamma)^2}} \tag{39}$$

Therefore, when $C_b$ is sufficiently large, it follows that

$$(Q^* - Q_t)(s, \pi^*(s)) \leq \gamma \sum_{i=1}^{n} \eta_i^n P_{s,\pi^*(s)}(V^* - V_{k_i}) + 3C_b \sqrt{\frac{Ht}{n (1 - \gamma)^2}}.$$

Taking the union bound over $s \in S$ and defining

$$\beta_n(s, \pi^*(s)) := 3C_b \sqrt{\frac{Ht}{n (1 - \gamma)^2}},$$

we can conclude that with probability exceeding $1 - \delta$,

$$(Q^* - Q_t)(s, \pi^*(s)) \leq \gamma \sum_{i=1}^{n} \eta_i^n P_{s,\pi^*(s)}(V^* - V_{k_i}) + \beta_n(s, \pi^*(s))$$

for all $s \in S$ and $t \in [T]$.

Additionally, observe that $V^* \geq V_{\pi_t}$ holds trivially due to the optimality of $V^*$. We are therefore left with showing $V_{\pi_t} \geq V_t$. Suppose for the moment that with probability exceeding $1 - \delta$, for all $s \in S$, $t \in [T]$ and $j \in [t]$, it holds that

$$(Q_{\pi_t} - Q_j)(s, \pi_t(s)) \geq \gamma P_{s,\pi_t(s)}(V_{\pi_t} - V_j) \mathbb{1}_{n_t(s, \pi_t(s)) \geq 1}; \tag{40}$$

the proof of this claim (40) is deferred to Appendix C.A.1. As a consequence, for every $s \in S$ and $t \in [T]$, there exists $j(t) \in [t]$ such that

$$(V_{\pi_t} - V_t)(s) \overset{(i)}{=} Q_{\pi_t}(s, \pi_t(s)) - Q_{j(t)}(s, \pi_t(s)) \overset{(ii)}{=} Q_{\pi_t}(s, \pi_t(s)) - Q_{j(t)}(s, \pi_{j(t)}(s)) \overset{(iii)}{=} \min \left\{ \gamma P_{s,\pi_t(s)}(V_{\pi_t} - V_{j(t)}) , 0 \right\} \overset{(iv)}{=} \min \left\{ \gamma P_{s,\pi_{j(t)}(s)}(V_{\pi_t} - V_{j(t)}) , 0 \right\}.$$
1) Proof of Inequality (40): First of all, if \( n_t(s, \pi_t(s)) = 0 \), then for all \( j \in [t] \), \( Q_j(s, \pi_t(s)) = 0 \) since it is never updated; therefore, (40) holds true. From now on, we shall only focus on the case when \( n_t(s, \pi_t(s)) \geq 1 \).

Consider any \( s \in S \), \( t \in [T] \) and \( j \in [t] \). For the moment, let us define \( \{k_i\}_{i=1}^{\tau} \) w.r.t. the state-action pair \( (s, \pi_t(s)) \) in the same way as (36). We can then repeat the argument in (37) to obtain (41), shown at the bottom of the page. In (41), the last inequality follows from (39), as well as the facts that \( \sum_{i=1}^{n_j(s, \pi_t(s))} \eta_i n_j(s, \pi_t(s)) = 1 \) (cf. Lemma 1) and that \( V_i \) is non-decreasing in \( t \). It thus boils down to showing that for every \( s \in S \), \( t \in [T] \) and \( j \in [t] \),

\[
\sum_{i=1}^{n_j(s, \pi_t(s))} \eta_i n_j(s, \pi_t(s)) \gamma \left( (P - P_{k_i}) V_{k_i} \right)(s, \pi_t(s)) \leq \sqrt{\frac{H_t}{n_j(s, \pi_t(s)) (1 - \gamma)^2}}.
\]

(42)

If this were true and if \( C_b \) is sufficiently large, then we could combine the above two inequalities to conclude the proof of (40).

We then prove the inequality (42). Notice that for all \( (s, \pi_t(s)) \) such that \( n_t(s, \pi_t(s)) \geq 1 \), it must appear at least once in the sample trajectory. Therefore, it suffices to show that for all \( 0 \leq t < T \) and \( t \in [T] \), it holds that

\[
\sum_{i=1}^{n_t(s, a_t)} \eta_i n_t(s, a_t) \gamma \left( (P - P_{k_i}) V_{k_i} \right)(s, a_t) \leq \sqrt{\frac{H_t}{n_t(s, a_t) (1 - \gamma)^2}},
\]

where we abuse the notation by defining \( \{k_i\}_{i=1}^{\tau} \) for the state-action pair \( (s, a_t) \) in the same way as (36). Furthermore, it suffices to only check those \( (s, a_t) \) in the sample trajectory that were visited for the first time, i.e., \( n_t(s, a_t) = 0 \) and \( n_{t+1}(s, a_t) = 1 \). It is straightforward to check that, for any \( 1 \leq \tau \leq T \),

\[
\left\{ \mathbb{1}_{k_i < T} \left((P - P_{k_i}) V_{k_i}\right)(s, a_t) \right\}^\tau_i \leq \frac{1}{1 - \gamma} \sqrt{\frac{H_t}{(1 - \gamma)^2}}.
\]

Taking the union bound over \( \tau \in [T] \) allows us to replace \( \tau \) with \( n_t(s, a_t) \) in the above inequality, namely, this shows that for any such \( (s, a_t) \), with probability exceeding \( 1 - \delta/T^2 \) we have

\[
\sum_{i=1}^{n_t(s, a_t)} \eta_i n_t(s, a_t) \gamma \left( (P - P_{k_i}) V_{k_i} \right)(s, a_t) \leq \sqrt{\frac{H_t}{n_t(s, a_t) (1 - \gamma)^2}}
\]

for all \( t \in [T] \). Taking the union bound over all such \( (s, a_t) \) (which are concerned with at most \( T \) pairs), we see that with probability exceeding \( 1 - \delta \),

\[
\sum_{i=1}^{n_t(s, a_t)} \eta_i n_t(s, a_t) \gamma \left( (P - P_{k_i}) V_{k_i} \right)(s, a_t) \leq \sqrt{\frac{H_t}{n_t(s, a_t) (1 - \gamma)^2}}.
\]
is valid for any $0 \leq j < T$ and any $t \in [T]$. This establishes the inequality (42), thus concluding the proof.

B. Proof of Lemma 3

For each $(s, \pi^*(s)) \in \mathcal{I}^c$, we first have

$$\mathbb{P}\left\{ \left( s_t, a_t \right) = (s, \pi^*(s)) \mid (s_0, a_0) \sim \mu_b \right\} \leq \delta \frac{ST}{T},$$

given that $\mu_b$ is taken to be the stationary distribution of the sample trajectory. By virtue of the union bound, we obtain

$$\mathbb{P}\left\{ \mathcal{I}^c \cap \{(s_t, a_t)\}_{t=0}^T = \emptyset \mid (s_0, a_0) \sim \mu_b \right\} \geq 1 - \sum_{t=t_{\text{min}}(s, \pi^*(s))}^{T} \mathbb{P}\left\{ (s_t, a_t) = (s, \pi^*(s)) \mid (s_0, a_0) \sim \mu_b \right\} > 1 - \delta.$$

In addition, for an arbitrary pair $(s, a) \in \mathcal{S} \times \mathcal{A}$, the definition of the mixing time gives

$$\mathbb{P}\left\{ \{(s_t, a_t)\}_{t=t_{\text{min}}(s, a)}^T \subseteq \mathcal{I} \mid (s_0, a_0) \sim \mu_b \right\} \geq 1 - 2\delta.$$

Combine the above results to yield

$$\mathbb{P}\left\{ \{(s_t, a_t)\}_{t=t_{\text{min}}(s, a)}^T \subseteq \mathcal{I} \mid (s_0, a_0) = (s, a) \right\} \geq 1 - 2\delta$$

for an arbitrary pair $(s, a) \in \mathcal{S} \times \mathcal{A}$.

C. Proof of Lemma 4

For any given integer $K > 0$, one can decompose

$$\sum_{j=0}^{\infty} \gamma \left[ \left( 1 + \frac{1}{H} \right)^{3j} \right] \langle \rho(P_{\pi^*}), V \rangle$$

$$= \left( \sum_{j=0}^{K} + \sum_{j=K}^{\infty} \right) \gamma \left[ \left( 1 + \frac{1}{H} \right)^{3j} \right] \langle \rho(P_{\pi^*}), V \rangle$$

$$\leq \left( 1 + \frac{1}{H} \right)^{3K} \sum_{j=0}^{\infty} \gamma^j \langle \rho(P_{\pi^*}), V \rangle$$

$$+ \sum_{j=K}^{\infty} \left[ \gamma \left( 1 + \frac{1}{H} \right)^{3j} \right] \||V||\infty$$

$$\leq \left( 1 + \frac{1}{H} \right)^{3K} \frac{1}{1 - \gamma} \langle d_{\rho}^*, V \rangle$$

$$+ \gamma^K \left( 1 + \frac{1}{H} \right)^{3K} \frac{1}{1 - \gamma \left( 1 + \frac{1}{H} \right)^3} ||V||\infty .$$

Here, the last inequality holds since $d_{\rho}^* = (1 - \gamma) \sum_{j=0}^{\infty} \gamma^j \rho(P_{\pi^*})^j$.

By taking

$$K = H = \left[ \frac{4}{1 - \gamma} \log \frac{ST}{\delta} \right] ,$$

we can derive

$$\left( 1 + \frac{1}{H} \right)^{3K} = \left( 1 + \frac{1}{H} \right)^{3H (i)} \leq e^3 = O(1)$$

and

$$\gamma^K = e^{K \log \left( 1 - (1 - \gamma) \right) (ii)} \leq e^{-K(1 - \gamma)} = \frac{\delta}{ST^4}.$$

Here, (i) holds since $(1 + 1/x)^2 \leq e$ for all $x > 0$; (ii) is valid since $\log(1 - x) \leq -x$ for all $x \in (0, 1)$. It is also worth noting that

$$\frac{1}{1 - \gamma \left( 1 + \frac{1}{H} \right)^3 \frac{1}{1}} \leq \frac{1}{1 - \gamma \left[ 1 + \frac{b1}{61} (1 - \gamma) \right]}$$

$$= \frac{1}{(1 - \gamma) \left( 1 + \frac{61}{61} \gamma \right)} \leq 1 - \gamma,$$

where (iii) holds since $(1 + x)^2 \leq 1 + 61x/16$ for all $0 < x \leq 1/4$. We then immediately arrive at

$$\alpha_1 \leq \frac{1}{1 - \gamma} \langle d_{\rho}^*, V \rangle$$

and

$$\alpha_2 \leq \frac{\delta}{ST^4 (1 - \gamma) \|V\|\infty} .$$

Taking the upper bounds on $\alpha_1$ and $\alpha_2$ collectively leads to the advertised inequality

$$\sum_{j=0}^{\infty} \left[ \gamma \left( 1 + \frac{1}{H} \right)^{3j} \right] \langle \rho(P_{\pi^*}), V \rangle$$

$$\leq \frac{1}{1 - \gamma} \langle d_{\rho}^*, V \rangle + \frac{\delta}{ST^4 (1 - \gamma) \|V\|\infty} .$$

D. Proof of Lemma 5

For notational simplicity, we denote

$$X_t := (s_t, a_t), \quad 1 \leq t \leq T;$$

clearly, $\{X_t\}_{t \geq 0}$ forms a Markov chain on $\mathcal{X} \triangleq \mathcal{S} \times \mathcal{A}$, with stationary distribution $\mu_b$. In what follows, we demonstrate how to construct the sequence $Y_{K-1} = (s_{K-1}, a_{K-2}), Y_{K-2} = (s_{K-2}, a_{K-2}), \ldots, Y_1 = (s_1, a_1)$ so as to satisfy the desired properties.

Let us start by constructing $Y_{K-1}$. Recall from the definition of the mixing time that: for any fixed state-action pairs $x_0, x_1, \ldots, x_{(K-2)\tau+i} \in \mathcal{X}$, one has

$$\text{TV}(\mathcal{L}(X_{(K-1)\tau+i} \mid X_0 = x_0, \ldots, X_{(K-2)\tau+i} = x_{(K-2)\tau+i}) ,$$

$$\mu_b) \leq \frac{\delta}{T^2} .$$

where $\mathcal{L}(\cdot)$ denotes the law of the random variable. In view of the definition of the total-variation distance, we know that there exists a random variable $Y_{K-1}^{x_0, \ldots, x_{(K-2)\tau+i}}$ such that conditional on the event $X_0 = x_0, \ldots, X_{(K-2)\tau+i} = x_{(K-2)\tau+i}$, the law of $Y_{K-1}^{x_0, \ldots, x_{(K-2)\tau+i}}$ obeys

$$\mathcal{L}(Y_{K-1}^{x_0, \ldots, x_{(K-2)\tau+i}} \mid X_0 = x_0, \ldots, X_{(K-2)\tau+i} = x_{(K-2)\tau+i})$$

$$= \mu_b ,$$
and $Y_{K-1}^{x_0, \cdots, x_{(K-2)+i}}$ is almost identical to $X_{(K-1)+i}$ in the sense that
\[
P \left( X_{(K-1)+i} \neq Y_{K-1}^{x_0, \cdots, x_{(K-2)+i}} \mid X_0 = x_0, \ldots, X_{(K-2)+i} = x_{(K-2)+i} \right) \leq \frac{\delta}{T^2}.
\]
As a consequence, we can construct $Y_{K-1}^i$ as follows
\[
Y_{K-1}^i := \sum_{x_0, \ldots, x_{(K-2)+i} \in \mathcal{X}} Y_{K-1}^{x_0, \cdots, x_{(K-2)+i}} \cdot \mathbb{1} \left\{ X_0 = x_0, \ldots, X_{(K-2)+i} = x_{(K-2)+i} \right\};
\]
as can be easily verified, for any $x_0, x_1, \ldots, x_{(K-2)+i} \in \mathcal{X}$ one has
\[
\mathcal{L} \left( Y_{K-1}^i \mid X_0 = x_0, \ldots, X_{(K-2)+i} = x_{(K-2)+i} \right) = \mathcal{L} \left( Y_{K-1}^{x_0, \cdots, x_{(K-2)+i}} \mid X_0 = x_0, \ldots, X_{(K-2)+i} = x_{(K-2)+i} \right) = \mu_b.
\]
All this in turn implies that
\[
Y_{K-1}^i \sim \mu_b \text{ and } Y_{K-1}^i \perp \{X_0, X_1, \ldots, X_{(K-2)+i}\}.
\]
In addition, it is also seen that (44), shown at the bottom of the page, holds.

Next, we turn to the construction of $Y_{K-2}^i$. Consider any fixed $x_0, x_1, \ldots, x_{(K-3)+i}, y_{K-1} \in \mathcal{X}$. Given that $Y_{K-1}^i \perp \{X_0, X_1, \ldots, X_{(K-2)+i}\}$, the conditional law of $X_{(K-2)+i}$ obeys
\[
\mathcal{L} \left( X_{(K-2)+i} \mid X_0 = x_0, \ldots, X_{(K-3)+i} = x_{(K-3)+i}, Y_{K-1}^i = y_{K-1} \right) = \mathcal{L} \left( X_{(K-2)+i} \mid X_0 = x_0, \ldots, X_{(K-3)+i} = x_{(K-3)+i} \right) = \mu_b.
\]
This in turn allows one to obtain
\[
\text{TV} \left( \mathcal{L} \left( X_{(K-2)+i} \mid X_0 = x_0, \ldots, X_{(K-3)+i} = x_{(K-3)+i}, Y_{K-1}^i = y_{K-1} \right), \mu_b \right) \leq \frac{\delta}{T^2}.
\]
According to the definition of the total-variation distance, there exists a random variable $Y_{K-2}^{x_0, \cdots, x_{(K-3)+i}, y_{K-1}}$ such that: conditional on the event $X_0 = x_0, \ldots, X_{(K-3)+i} = x_{(K-3)+i}, Y_{K-1}^i = y_{K-1}$, the law of $Y_{K-2}^{x_0, \cdots, x_{(K-3)+i}, y_{K-1}}$ obeys
\[
\mathcal{L} \left( Y_{K-2}^{x_0, \cdots, x_{(K-3)+i}, y_{K-1}} \mid X_0 = x_0, \ldots, X_{(K-3)+i} = x_{(K-3)+i}, Y_{K-1}^i = y_{K-1} \right) = \mu_b,
\]
and $Y_{K-2}^{x_0, x_1, \cdots, x_{(K-3)+i}, y_{K-1}}$ is almost identical to $X_{(K-2)+i}$ in the following sense
\[
P \left( X_{(K-2)+i} \neq Y_{K-2}^{x_0, x_1, \cdots, x_{(K-3)+i}, y_{K-1}} \mid X_0 = x_0, \ldots, X_{(K-2)+i} = x_{(K-2)+i} \right) \leq \frac{\delta}{T^2}.
\]
With the above set of random variables in mind, we can readily construct $Y_{K-2}^i$ as follows:
\[
Y_{K-2}^i := \sum_{x_0, x_1, \cdots, x_{(K-3)+i}, y_{K-1} \in \mathcal{X}} Y_{K-2}^{x_0, x_1, \cdots, x_{(K-3)+i}, y_{K-1}} \cdot \mathbb{1} \left\{ X_0 = x_0, \ldots, X_{(K-3)+i} = x_{(K-3)+i}, Y_{K-1}^i = y_{K-1} \right\}.
\]
As can be straightforwardly verified, for any $x_0, x_1, \ldots, x_{(K-3)+i}, y_{K-1} \in \mathcal{X}$ we have
\[
\mathcal{L} \left( Y_{K-2}^i \mid X_0 = x_0, \ldots, X_{(K-3)+i} = x_{(K-3)+i}, Y_{K-1}^i = y_{K-1} \right) = \mathcal{L} \left( Y_{K-2}^{x_0, x_1, \cdots, x_{(K-3)+i}, y_{K-1}} \mid X_0 = x_0, \ldots, X_{(K-3)+i} = x_{(K-3)+i}, Y_{K-1}^i = y_{K-1} \right) = \mu_b,
\]
thus implying that $Y_{K-2}^i \sim \mu_b$ and
\[
Y_{K-2}^i \perp \{X_0, X_1, \ldots, X_{(K-3)+i}, Y_{K-1}^i\}.
\]
This reveals that $Y_{K-2}^1, Y_{K-2}^2, \ldots, Y_{K-2}^i$ sequentially such that $Y_{K-2}^1 \sim \mu_b$, and for all $1 \leq k \leq K - 1$, $Y_{K-2}^i \perp \{X_0, X_1, \ldots, X_{(K-1)+i}\}$, and $P \left( Y_{K-2}^i = X_{(K-1)+i} \right) \leq \frac{\delta}{T^2}$. As a result, we arrive at
\[
\forall 1 \leq k \leq K - 1, \quad V_{K-2}^{Y_{K-2}^i} = V_{K-2}^i \sim \mu_b.
\]
This concludes the proof.

**APPENDIX D**

**ANALYSIS FOR VARIANCE-REDUCED Q-LEARNING WITH LCB PENALIZATION (THEOREM 2)**

This section presents the proof of Theorem 2, which is concerned with the performance of variance-reduced Q-learning with LCB penalization. Recall that $V_{k+1} = V_{k}$, that is, the value estimate in the last iterate of the $k$-th epoch

\[
P \left( Y_{K-1}^i \neq X_{(K-1)+i} \right) = \sum_{x_0, \ldots, x_{(K-2)+i} \in \mathcal{X}} P \left( X_0 = x_0, \ldots, X_{(K-2)+i} = x_{(K-2)+i} \right) \cdot P \left( X_{(K-1)+i} \neq Y_{K-1}^i \mid X_0 = x_0, \ldots, X_{(K-2)+i} = x_{(K-2)+i} \right) \leq \frac{\delta}{T^2} \sum_{x_0, \ldots, x_{(K-2)+i} \in \mathcal{X}} P \left( X_0 = x_0, \ldots, X_{(K-2)+i} = x_{(K-2)+i} \right) = \frac{\delta}{T^2}.
\]

\section*{APPENDIX D}

**ANALYSIS FOR VARIANCE-REDUCED Q-LEARNING WITH LCB PENALIZATION (THEOREM 2)**

This section presents the proof of Theorem 2, which is concerned with the performance of variance-reduced Q-learning with LCB penalization. Recall that $V_{k+1} = V_{k}$, that is, the value estimate in the last iterate of the $k$-th epoch
is also used as the reference for the \((k+1)\)-th epoch. For each \(1 \leq k \leq K\), we define

\[
\Lambda_k := \sum_{s \in S} \rho(s) \left( V^* - \nabla_k(s) \right)
\]  

Clearly, the proof of Theorem 2 boils down to bounding \(\Lambda_K\). As we shall see momentarily, obtaining a tight bound on \(\Lambda_k\) relies on bounding another closely related quantity \(\Delta_{K-1}\), define for each \(1 \leq k \leq K\) as follows:

\[
\Delta_k := \sum_{s \in S} \tilde{\rho}(s) \left( V^* - \nabla_k(s) \right).
\]

Here, we set

\[
\tilde{\rho} := \frac{d^*_i - (1 - \gamma) \rho}{\gamma}
\]

The sequence \(\{\Delta_k\}_{k=1}^K\) will be bounded by induction in the sequel. We shall present our proof by describing three key steps following some preliminary facts.

**A. Preliminary Facts About the \(k\)-Th Epoch**

Let us first look at what happens in the \(k\)-th epoch. For notational simplicity, we will denote \(\nabla := \nabla_{k-1}\). Similar to the proof of Theorem 1, for any iterate \(t \leq T_k\), let \(n = n_t(s, a)\) and assume that \((s, a)\) has been visited during the iterations \(k_1 < \cdots < k_n < t\). We also need to define the policy \(\pi_t: S \rightarrow A\) as follows

\[
\pi_t(s) := \arg \max_{a \in A} Q_t(s, \pi(s)),
\]

if \(s = s_{t-1}\) and \(V_t(s) > V_{t-1}(s)\), and

\[
\pi_t(s) := \pi_{t-1}(s)
\]

otherwise. If there are multiple \(a \in A\) that maximize \(Q_t(s_{t-1}, a)\) simultaneously, then we can go with any of them. We make note of the following lemma.

**Lemma 6:** With probability exceeding \(1 - \delta\), for any \(s \in S\) and \(t \in [T]\) we have

\[
(Q^* - Q_t) \left( s, \pi^*(s) \right) \\
\leq \gamma \sum_{i=1}^{\eta_t(s, a)} \rho s_{a} \left( V^* - V_{k_i} \right) + \beta_n \left( s, \pi^*(s) \right),
\]

where \(n = n_t(s, \pi^*(s))\) and

\[
\beta_n(s, a) := 3C_b \sqrt{\frac{H_t}{n} \left\{ \sigma^{adv}_n(s, a) - \left[ \mu^{adv}_n(s, a) \right]^2 \right\}^2} + 3C_b \frac{H_t}{n(1 - \gamma)} + 3C_b \frac{H_t}{n(1 - \gamma)}
\]

In addition, it holds that

\[
V_t(s) \leq V_{\pi^*(s)} \leq V^*(s)
\]

for all \(s \in S\) and \(1 \leq t \leq T_k\).

**Proof:** See Appendix E-A.

Moreover, both \(\sigma^{adv}_n(s, a)\) and \(\sigma^{ref}(s, a) - \left[ \mu^{ref}(s, a) \right]^2\) play an important role in determining the variance of the update, and we are in need of the following bounds on these two quantities.

**Lemma 7:** With probability exceeding \(1 - \delta\), for all \(s \in S\) and \(t \in [T_k]\) we have

\[
\sigma^{adv}_n(s, \pi^*(s)) \leq P_{s, \pi^*(s)} \left( V^* - \nabla \right) + O \left( \frac{1}{(1 - \gamma)^2} \sqrt{n_t(s, \pi^*(s))} \right)
\]

and

\[
\sigma^{ref}(s, \pi^*(s)) - \left[ \mu^{ref}(s, \pi^*(s)) \right]^2 = \text{Var}_{s, \pi^*(s)}(\nabla) + O \left( \frac{1}{(1 - \gamma)^2} \sqrt{n_t(s, \pi^*(s))} \right).
\]

In addition, it holds that

\[
\sum_{s \in S, a \in A} d^*_i(s, a) \text{Var}_{s, a}(V^* - \nabla) \leq \frac{1}{1 - \gamma} \Delta_{k-1};
\]

\[
\sum_{s \in S, a \in A} d^*_i(s, a) \text{Var}_{s, a}(\nabla) \leq \frac{8}{1 - \gamma} + \frac{2}{1 - \gamma} \Delta_{k-1}.
\]

**Proof:** See Appendix E-B.

**B. Step 1: Connecting \(\Lambda_k\) With \(\Delta_{k-1}\)**

In this step, we aim to establish a connection between \(\Lambda_k\) (cf. (46)) and \(\Delta_{k-1}\) (cf. (47)). In view of the monotonicity of \(V_t\) in \(t\) (by construction) and Lemma 6, we can derive

\[
\Lambda_k = \left\langle \rho, V^* - V_{T_k} \right\rangle \leq \frac{1}{T_k} \sum_{i=1}^{T_k} \left\langle \rho, V^* - V_i \right\rangle.
\]

Before continuing, we find it convenient to introduce a set of quantities in (51), shown at the bottom of the next page,
similar to our proof for Theorem 1. Repeat the same analysis as in Step 1 of the proof of Theorem 1 (which we omit here for brevity) to yield

$$\alpha_0 \leq \lim_{j \to \infty} \sup_{\tau} \sum_{j=0}^{\tau} \xi_j + \sum_{j=0}^{\tau} \theta_j + \sum_{j=0}^{\tau} \psi_j + \sum_{j=0}^{\tau} \phi_j,$$

as well as the properties that $\alpha = 0$,

$$\xi \leq 2t_{\text{mix}} \log \frac{1}{\delta} + \frac{t_{\text{mix}}}{T^4 (1 - \gamma)^3} \log \frac{1}{\delta},$$

$$\psi \leq C^* t_{\text{mix}} (1 - \gamma)^3 \log^2 \left( \frac{T}{\delta} \right) + C^* S t_{\text{mix}} (1 - \gamma)^3 \log \left( \frac{T}{\delta} \right),$$

$$\phi \leq C^* t_{\text{mix}} (1 - \gamma)^3 \log^2 \left( \frac{T}{\delta} \right) + C^* S t_{\text{mix}} (1 - \gamma)^3 \log \left( \frac{T}{\delta} \right).$$

It then comes down to bounding $\theta$, which is different from what has been done in the proof of Theorem 1. Towards this, we first invoke Lemma 4 to reach

$$\theta = \sum_{t=1}^{T_k} \sum_{j=0}^{\infty} \left[ \left( 1 + \frac{1}{H^j} \right)^3 \sum_{s \in S} \rho(P_{\pi'})^j (s, \pi^*(s)) \right] \cdot \min \left\{ \beta_{n_t(s, \pi^*(s))} (s, \pi^*(s)), \frac{1}{1 - \gamma} \right\}$$

$$\leq \frac{1}{1 - \gamma} \sum_{t=1}^{T_k} \sum_{s \in S} d^*_p(s) \min \left\{ \beta_{n_t(s, \pi^*(s))} (s, \pi^*(s)), \frac{1}{1 - \gamma} \right\} + \frac{1}{ST^4 (1 - \gamma)} \frac{T}{1 - \gamma}.$$

To proceed, let us use the definition of $\beta_n(s, a)$ (cf. (49)) to achieve the decompose (53), shown at the bottom of the next page, where we define, for each $s \in S$, that

$$t_{\text{burn-in}}(s) := C_{\text{burn-in}} \frac{t_{\text{mix}}}{\mu_b(s, \pi^*(s))} \log \left( \frac{ST}{\delta} \right)$$

for some sufficiently large constant $C_{\text{burn-in}} > 0$.

Before continuing, we first collect a few immediate and useful results of [8, Lemma 8]: with probability exceeding $1 - \delta$, we have

$$n_t(s, \pi^* (s)) \geq \mu_b(s, \pi^*(s))$$

for all $s \in S$ and $t_{\text{burn-in}}(s) \leq t \leq T_k$; in addition, when $T_k^{\text{ref}} \approx T_k \geq t_{\text{burn-in}}(s)$, one has

$$n^\text{ref}(s, \pi^*(s)) \geq T_k^{\text{ref}} \mu_b(s, \pi^*(s)),$$

provided that $C_{\text{burn-in}}$ is large enough. We then bound the terms $\omega_0, \ldots, \omega_6$ separately.

- The first bound $\omega_0$ can be easily bounded by

$$\omega_0 \leq \sum_{s \in S} \frac{t_{\text{burn-in}}(s) d^*_p(s)}{1 - \gamma}$$

$$\leq \sum_{s \in S} \frac{t_{\text{mix}}}{\mu_b(s, \pi^*(s))} d^*_p(s, \pi^*(s)) \frac{1}{1 - \gamma}$$

$$\leq \sum_{s \in S} \frac{C^* t_{\text{mix}}}{1 - \gamma} \mu_b(s, \pi^*(s)) \leq \frac{C^* S t_{\text{mix}}}{1 - \gamma},$$

where the last line follows from Assumption 2.

- To control $\omega_1$, we observe that

$$\omega_1 \leq \sum_{s \in S} \frac{t_{\text{burn-in}}(s) d^*_p(s)}{1 - \gamma} \times \frac{Ht}{n_t(s, \pi^*(s)) \sigma^*_t(s, \pi^*(s))}$$
Here, (i) follows from (54); (ii) utilizes Assumption 2; (v) comes from Lemma 7 and the definition of $H$ (i.e., $H \approx \frac{1}{1-\gamma}$). The other term $\omega_{1,2}$ is identical to $\omega_3$, which we shall bound momentarily.

- When it comes to $\omega_{2}$, we apply Lemma 7 to reach

$$
\omega_{2} \leq \sum_{s \in S, t=t_{burn-in}(s)} T_k d^*_p(s, \pi^*(s)) \sqrt{\frac{H_t}{n_t(s, \pi^*(s))}} P_{s, \pi^*(s)} (V^* - V)^2 + \sum_{s \in S, t=t_{burn-in}(s)} T_k d^*_p(s, \pi^*(s)) \sqrt{\frac{l}{n_{ref}^t(s, \pi^*(s))}} \text{Var}_{s, \pi^*(s)}(V)
$$

where the last inequality follows from Lemma 7. The first term $\omega_{1,1}$ admits the following bound

$$
\omega_{1,1} \leq \sum_{s \in S, t=t_{burn-in}(s)} T_k d^*_p(s, \pi^*(s)) \left( \frac{H_t}{t_{burn}(s, \pi^*(s))} P_{s, \pi^*(s)} (V^* - V)^2 + \sum_{s \in S, t=t_{burn-in}(s)} T_k d^*_p(s, \pi^*(s)) \frac{H t^{3/4} 3/4}{(1 - \gamma) n_t^{3/4}(s, \pi^*(s))} \right)
$$

Regarding $\omega_{2,1}$, we make the observation that

$$
\omega_{2,1} \leq \sum_{s \in S, t=t_{burn-in}(s)} T_k d^*_p(s, \pi^*(s)) \left( \sqrt{\frac{C^* H t}{T_k t_{burn}(s, \pi^*(s))}} \text{Var}_{s, \pi^*(s)}(V) + \sum_{s \in S, a \in A} T_k d^*_p(s, a) \sqrt{\text{Var}_{s,a}(V)} \right)
$$

$$
\omega_{2,2} \leq \sum_{s \in S, a \in A} T_k d^*_p(s, a) \frac{1}{1 - \gamma} + \sqrt{C^* S t_{burn}^2 T_k (1 - \gamma) \Delta_{k-1}}.
$$

Here, (i) follows from (54); (ii) utilizes Assumption 2; (iii) arises from (27); (iv) applies the Cauchy-Schwarz inequality; and (v) comes from Lemma 7 and the definition of $H$ (i.e., $H \approx \frac{1}{1-\gamma}$). The other term $\omega_{1,2}$ is identical to $\omega_3$, which we shall bound momentarily.

- When it comes to $\omega_{2}$, we apply Lemma 7 to reach

$$
\omega_{2} \leq \sum_{s \in S, t=t_{burn-in}(s)} T_k d^*_p(s, \pi^*(s)) \sqrt{\frac{H_t}{n_t(s, \pi^*(s))}} P_{s, \pi^*(s)} (V^* - V)^2 + \sum_{s \in S, t=t_{burn-in}(s)} T_k d^*_p(s, \pi^*(s)) \sqrt{\frac{l}{n_{ref}^t(s, \pi^*(s))}} \text{Var}_{s, \pi^*(s)}(V)
$$

where the last inequality follows from Lemma 7. The first term $\omega_{1,1}$ admits the following bound

$$
\omega_{1,1} \leq \sum_{s \in S, t=t_{burn-in}(s)} T_k d^*_p(s, \pi^*(s)) \left( \frac{H_t}{t_{burn}(s, \pi^*(s))} P_{s, \pi^*(s)} (V^* - V)^2 + \sum_{s \in S, t=t_{burn-in}(s)} T_k d^*_p(s, \pi^*(s)) \frac{H t^{3/4} 3/4}{(1 - \gamma) n_t^{3/4}(s, \pi^*(s))} \right)
$$

Regarding $\omega_{2,1}$, we make the observation that

$$
\omega_{2,1} \leq \sum_{s \in S, t=t_{burn-in}(s)} T_k d^*_p(s, \pi^*(s)) \left( \sqrt{\frac{C^* H t}{T_k t_{burn}(s, \pi^*(s))}} \text{Var}_{s, \pi^*(s)}(V) + \sum_{s \in S, a \in A} T_k d^*_p(s, a) \sqrt{\text{Var}_{s,a}(V)} \right)
$$

$$
\omega_{2,2} \leq \sum_{s \in S, a \in A} T_k d^*_p(s, a) \frac{1}{1 - \gamma} + \sqrt{C^* S t_{burn}^2 T_k (1 - \gamma) \Delta_{k-1}}.
$$

Here, (i) follows from (54); (ii) utilizes Assumption 2; (iii) arises from (27); (iv) applies the Cauchy-Schwarz inequality; and (v) comes from Lemma 7 and the definition of $H$ (i.e., $H \approx \frac{1}{1-\gamma}$). The other term $\omega_{1,2}$ is identical to $\omega_3$, which we shall bound momentarily.
Here, (i) relies on (55); (ii) invokes Assumption 2; (iii) utilizes the Cauchy-Schwarz inequality; and (iv) follows from Lemma 7. The other term \( \omega_{2,3} \) is the same as \( \omega_5 \), which will be bounded momentarily.

- Regarding \( \omega_3 \), we have
  \[
  \omega_3 \sim \sum_{s \in S} \sum_{t=1}^{T_k} d_p^*(s, \pi^*(s)) \left( H^3/4/3/4 \right) \frac{(1 - \gamma) t^{3/4} H_k^{3/4} (s, \pi^*(s))}{(1 - \gamma)} \]  

  - (i) follows from (54); (ii) relies on (55); (iii) invokes Assumption 2; and (iv) holds since \( T_k^\text{ref} \approx T_k \).

- We are left with bounding the last term \( \omega_6 \), towards which we observe
  \[
  \omega_6 \leq \sum_{s \in S} \sum_{t=1}^{T_k} d_p^*(s, \pi^*(s)) \frac{1}{(1 - \gamma) T_k^\text{ref} H_b(s, \pi^*(s))} \]

  - (i) follows from (55); (ii) utilizes Assumption 2; and (iii) holds since \( T_k^\text{ref} \approx T_k \).

Taking the preceding bounds on \( \omega_1, \omega_2, \omega_3, \omega_4, \omega_5, \) and \( \omega_6 \) together with (52) and (53) yields

\[
\theta \leq 1 \frac{1}{1 - \gamma} \sum_{t=1}^{T_k} d_p^*(s) \min \left\{ \beta_{nt(s, \pi^*(s))}, \frac{1}{1 - \gamma} \right\} 
+ \frac{1}{ST^4 (1 - \gamma) (1 - \gamma)} T_k 
\leq \frac{1}{1 - \gamma} (\omega_0 + \omega_1 + \omega_2 + \omega_3 + \omega_4 + \omega_5 + \omega_6) 
+ \frac{1}{ST^4 (1 - \gamma)} T_k 
\leq C^* S_{t_{\text{min}}^2} \left( \frac{(1 - \gamma)^2}{(1 - \gamma)^2} \right) + C^* S_{t_{\text{ref}}^2} \left( \frac{(1 - \gamma)^2}{(1 - \gamma)^2} \right) 
+ C^* S_{s_3} \left( \frac{(1 - \gamma)^2}{(1 - \gamma)^2} \right),
\]

where the last line has invoked the AM-GM inequality:

\[
2T_k^\text{ref} (C^* S_{t_{\text{ref}}^2}) \left( \frac{(1 - \gamma)^2}{(1 - \gamma)^2} \right) 
\leq T_k^\text{ref} (C^* S_{t_{\text{ref}}^2} (1 - \gamma)^2) \left( \frac{(1 - \gamma)^2}{(1 - \gamma)^2} \right) 
\leq T_k^\text{ref} (C^* S_{t_{\text{ref}}^2} (1 - \gamma)^2) \left( \frac{(1 - \gamma)^2}{(1 - \gamma)^2} \right) 
\leq T_k^\text{ref} (C^* S_{s_3} (1 - \gamma)^2) \left( \frac{(1 - \gamma)^2}{(1 - \gamma)^2} \right)
\]

Putting all of the above results together, we can conclude that

\[
\Delta_k \leq T_k^\text{ref} \alpha \leq \frac{1}{T_k} (\alpha + \xi + \theta + \psi + \phi)
\leq \frac{C^* S_{t_{\text{ref}}^2} \sqrt{\Delta_{k-1} + \Delta_k}}{T_k (1 - \gamma)^2} + \frac{C^* S_t}{T_k (1 - \gamma)^3}
+ \frac{C^* S_{t_{\text{ref}}^2}}{T_k (1 - \gamma)^2} + \frac{C^* S_{s_3} (1 - \gamma)^2}{T_k (1 - \gamma)^3}
\]

C. Step 2: Bounding \( \Delta_k \) by Induction

Thus far, we have established an intimate connection between \( \Delta_k \) and \( \Delta_k \) (see (58)). In order to bound \( \Delta_{k-1} \), we find it helpful to look at an auxiliary test distribution

\[
\tilde{\rho} = \frac{d_p^* - (1 - \gamma) \rho}{\gamma}
\]

Authorized licensed use limited to the terms of the applicable license agreement with IEEE. Restrictions apply.
instead of $\rho$. The following property about $\tilde{\rho}$ plays an important role in the subsequent analysis. 

**Lemma 8:** Suppose that $1/2 \leq \gamma < 1$. It holds that

$$
\sum_{j=0}^{\infty} \gamma \left( 1 + \frac{1}{H} \right)^j \langle \tilde{\rho}(P_{\gamma})^j, V \rangle 
\lesssim \frac{1}{1 - \gamma} \langle d_{\rho}^*, V \rangle \log \frac{ST}{\delta} + \frac{\delta}{ST^4(1 - \gamma)} \|V\|_{\infty}.
$$

**(Proof):** See Appendix E-C. □

Armed with Lemma 8, we can repeat the same analysis in Step 1 to bound each $\Delta_k$. The difference between (24) and (59) requires us to replace $d_{\rho}^*$ in Step 1 with $d_{\rho}^* \log(ST/\delta)$, which leads to

$$
\Delta_k \lesssim \sqrt{\frac{C^*S_{\text{st}}^4}{T_k(1 - \gamma)^3}} \sqrt{\Delta_{k-1}} + \sqrt{\frac{C^*S_{\text{st}}^3}{T_k(1 - \gamma)^3}} + \frac{C^*S_{\text{mix}}^2}{T_k(1 - \gamma)^3} + \frac{C^*S_{\text{mix}}^3}{T_k(1 - \gamma)^3}
$$

for each $1 \leq k \leq K$. The above inequality can be expressed as follows

$$
\Delta_k \leq \alpha_k \Delta_{k-1}^{1/2} + \beta_k,
$$

where

$$
\alpha_k = C \sqrt{\frac{C^*S_{\text{st}}^4}{T_k(1 - \gamma)^3}} = 2^{-k} A \quad \text{with} \quad A = C \sqrt{\frac{C^*S_{\text{st}}^4}{(1 - \gamma)^3}}
$$

and

$$
\beta_k = C \sqrt{\frac{C^*S_{\text{st}}^3}{T_k(1 - \gamma)^3}} + \frac{C^*S_{\text{mix}}^2}{T_k(1 - \gamma)^3} + \frac{C^*S_{\text{mix}}^3}{T_k(1 - \gamma)^3}
$$

for some sufficiently large constant $C > 0$. In addition, it is also observed that

$$
\Delta_0 \lesssim \frac{1}{1 - \gamma}.
$$

By induction, for each $1 \leq j \leq K$ we have

$$
\Delta_j \leq \beta_j + \alpha_j \beta_{j-1}^{1/2} + \alpha_j \alpha_{j-1}^{1/2} \beta_{j-2}^{1/4} + \cdots
$$

where

$$
\alpha_j = C \sqrt{\frac{C^*S_{\text{st}}^4}{T_j(1 - \gamma)^3}}, \quad \beta_j = C \sqrt{\frac{C^*S_{\text{st}}^3}{T_j(1 - \gamma)^3}} + \frac{C^*S_{\text{mix}}^2}{T_j(1 - \gamma)^3} + \frac{C^*S_{\text{mix}}^3}{T_j(1 - \gamma)^3}
$$

In the sequel, we bound each term $\delta_i$, $0 \leq i \leq j$ separately.

- **Let us begin with $\delta_0$, which can be calculated as follows**

$$
\delta_0 = A^{2-1/2^{i-1}} - j - 2^{1/2} - \cdots - 2^{1/2^{i-1}} \Delta_0^{1/2^i}.
$$

Note that

$$
\begin{align*}
& j + \frac{j - 1}{2} + \frac{j - 2}{4} + \cdots + \frac{1}{2^{j-1}} = \sum_{k=0}^{j-1} \frac{j - k}{2^k} \\
& = j \sum_{k=0}^{j-1} \frac{1}{2^k} - \sum_{k=0}^{j-1} \frac{k}{2^k} = j \left( 1 - \frac{2}{2^{j-1}} \right) - 2 + \frac{j + 1}{2^{j-1}} \\
& = 2j - 2 + \frac{1}{2^{j-1}},
\end{align*}
$$

where the penultimate line holds since

$$
\sum_{k=0}^{j-1} \frac{k}{2^k} = \sum_{k=1}^{j-1} \frac{1}{2^k} - \sum_{k=0}^{j-1} \frac{k}{2^k} = \sum_{k=0}^{j-2} \frac{1}{2^k} = j - 1 + \frac{1}{2^{j-1}}.
$$

Therefore we have

$$
\begin{align*}
\delta_0 & = A^{2-1/2^{i-1}} - j + 1/2 - 1/2^i \Delta_0^{1/2^i} \\
& \simeq \frac{1}{4j} \left[ C \sqrt{\frac{C^*S_{\text{st}}^4}{(1 - \gamma)^3}} \right]^{2^{-i} - 1/2^j} \left( \frac{1}{1 - \gamma} \right)^{1/2^j} \\
& \lesssim \frac{1}{T_j} \left[ C \sqrt{\frac{C^*S_{\text{st}}^4}{(1 - \gamma)^3}} \right]^{1-1/2^i} \left( \frac{1}{1 - \gamma} \right)^{1/2^j} \lesssim C^*S_{\text{st}}^4 \left( \frac{1}{1 - \gamma} \right)^{1/2^j} \lesssim T_j(1 - \gamma)^{1/2^j}.
\end{align*}
$$

- **Next, we develop a uniform bound on every $\delta_i$, $1 \leq i \leq j - 1$. We first observe that**

$$
\delta_i = \alpha_j \alpha_{j-1}^{1/2} \alpha_{j-2}^{1/4} \cdots \alpha_{j+1}^{1/2^{j-i-1}} \beta_j^{1/2^{j-i}}
$$

$$
= A^{2-1/2^{i-1}} - 2 + \frac{j + 1}{2^{j-i}} - \frac{j - j}{2^{j-i}} - \frac{2 - j}{2^{j-i}} \geq 2j - \frac{i}{2^{j-i}} - 2.
$$

These properties allow one to derive

$$
\begin{align*}
\delta_i & \lesssim A^{2-1/2^{i-1}} - 4^{-j+i/2^{i-i+1}} + 1/2^{j-i} \beta_j^{1/2^{j-i}} \\
& \simeq 4^{-j+i/2^{i-i}} \left[ C^*S_{\text{st}}^4 \right]^{1-1/2^i} \beta_j^{1/2^{j-i}} \\
& \simeq \frac{1}{T_j} \left[ C^*S_{\text{st}}^4 \right]^{1-1/2^i} \left( \frac{C^*S_{\text{st}}^3}{(1 - \gamma)^3} \right)^{1/2^i} \\
& + 4^{-j/2^{i-i+1}} \left[ C^*S_{\text{st}}^4 \right]^{1-1/2^i} \left( \frac{C^*S_{\text{st}}^3}{(1 - \gamma)^3} \right)^{1/2^i} \\
& + 4^{-j/2^{i-i+1}} \left( \frac{C^*S_{\text{st}}^4}{(1 - \gamma)^3} \right)^{1/2^i} \\
& + 4^{-j/2^{i-i+1}} \left( \frac{C^*S_{\text{st}}^3}{(1 - \gamma)^3} \right)^{1/2^i}.
\end{align*}
$$
Armed with the above results, we can readily conclude that
\[
\Delta_j \leq \delta_0 + \delta_j + j \max_{1 \leq s \leq j-1} \delta_s = \delta_0 + \beta_j + j \max_{1 \leq s \leq j-1} \delta_s
\]
\[
\leq \frac{C^* S t^4 j}{T_j (1 - \gamma)^3} + \frac{C^* S t^3 j}{T_j (1 - \gamma)^3} + \frac{C^* t_{\text{mix}}^3 j}{T_j (1 - \gamma)^3} + \frac{C^* t_{\text{mix}}^3 j}{T_j (1 - \gamma)^3}
\]
\[
+ C^* S t_{\text{mix}}^3 j T_j (1 - \gamma)^3 + \frac{C^* S t_{\text{mix}}^3 j T_j (1 - \gamma)^3}{T_j (1 - \gamma)^3} + \frac{C^* S t_{\text{mix}}^3 j T_j (1 - \gamma)^3}{T_j (1 - \gamma)^3}
\]
\[
\leq \frac{C^* S t^4 j}{T_j (1 - \gamma)^3} + \frac{C^* S t^3 j}{T_j (1 - \gamma)^3} + \frac{C^* t_{\text{mix}}^3 j}{T_j (1 - \gamma)^3} + \frac{C^* t_{\text{mix}}^3 j}{T_j (1 - \gamma)^3}
\]
\[
+ \frac{C^* S t_{\text{mix}}^3 j}{T_j (1 - \gamma)^3} + \frac{C^* t_{\text{mix}}^3 j}{T_j (1 - \gamma)^3} + \frac{C^* t_{\text{mix}}^3 j}{T_j (1 - \gamma)^3}
\]
\[
(60)
\]
where the last line relies on the fact that \(T_j^{1/2} \gtrsim 2j \gtrsim j\).

**D. Step 3: Putting All This Together**

Recall from (58) that
\[
\Lambda_K \leq \sqrt{\frac{C^* S t^2}{(1 - \gamma)^4}} \sqrt{\Delta_{K-1}} + \sqrt{\frac{C^* S t^3}{(1 - \gamma)^3} + \frac{C^* S t_{\text{mix}}^3}{(1 - \gamma)^3}} + \frac{C^* S t_{\text{mix}}^2}{(1 - \gamma)^3} + \frac{C^* t_{\text{mix}}^2}{(1 - \gamma)^3},
\]
which invokes the fact that \(T_K \sim T\). From (60) and the fact that \(T_K \sim T\), we see that
\[
\Delta_{K-1} \leq \frac{C^* S t^3}{T_j (1 - \gamma)^3} + \frac{C^* S t_{\text{mix}}^2}{T_j (1 - \gamma)^3} + \frac{C^* S t_{\text{mix}}^2}{T_1 (1 - \gamma)^3} + \frac{C^* t_{\text{mix}}^2}{T_j (1 - \gamma)^3}
\]
\[
+ \frac{C^* S t_{\text{mix}}^2}{T_j (1 - \gamma)^3} + \frac{C^* t_{\text{mix}}^2}{T_j (1 - \gamma)^3} + \frac{C^* t_{\text{mix}}^2}{T_j (1 - \gamma)^3}
\]
which in turn allows one to deduce that
\[
\sqrt{\frac{C^* S t^2}{(1 - \gamma)^4}} \sqrt{\Delta_{K-1}} \leq \left( \frac{C^* S t^2}{T_j (1 - \gamma)^4} \right)^{1/2} \left( \frac{C^* S t^3}{T_j (1 - \gamma)^3} \right)^{1/4}
\]
\[
= \delta_1
\]
\[
+ \left( \frac{C^* S t^2}{T_j (1 - \gamma)^4} \right)^{1/2} \left( \frac{C^* S t^4 \log T_j}{T_j (1 - \gamma)^4} \right)^{1/2}
\]
\[
= \delta_2
\]
\[
+ \left( \frac{C^* S t^2}{T_j (1 - \gamma)^4} \right)^{1/2} \left( \frac{C^* t^3 \log T_j}{T_j (1 - \gamma)^3} \right)^{1/2}
\]
\[
= \delta_3
\]
\[
+ \left( \frac{C^* S t^2}{T_j (1 - \gamma)^4} \right)^{1/2} \left( \frac{C^* t_{\text{mix}}^2 \log T_j}{T_j (1 - \gamma)^3} \right)^{1/2}
\]
\[
= \delta_4
\]
\[
+ \left( \frac{C^* S t^2}{T_j (1 - \gamma)^4} \right)^{1/2} \left( \frac{C^* t_{\text{mix}}^3 \log T_j}{T_j (1 - \gamma)^3} \right)^{1/2}
\]
\[
= \delta_5
\]
Here, the last step follows by applying the AM-GM inequality as follows:
\[
\delta_1 \leq \frac{C^* S t^3}{T_j (1 - \gamma)^3} + \frac{C^* S t_{\text{mix}}^3}{T_j (1 - \gamma)^3} + \frac{C^* t_{\text{mix}}^3}{T_j (1 - \gamma)^3},
\]
\[
\delta_2 \leq \frac{C^* S t_{\text{mix}}^2}{T_1 (1 - \gamma)^4},
\]
\[
\delta_3 \leq \frac{C^* S t_{\text{mix}}^2}{T_1 (1 - \gamma)^4},
\]
\[
\delta_4 \leq \frac{C^* S t_{\text{mix}}^2}{T_1 (1 - \gamma)^4} + \frac{C^* t_{\text{mix}}^2}{T_1 (1 - \gamma)^3},
\]
\[
\delta_5 \leq \frac{C^* S t_{\text{mix}}^2}{T_1 (1 - \gamma)^4} + \frac{C^* t_{\text{mix}}^2}{T_1 (1 - \gamma)^3},
\]
The above bounds taken collectively demonstrate that
\[
\Lambda_K \leq \frac{C^* S t}{T_j (1 - \gamma)^3} + \frac{C^* S t^3 \log T_j}{T_j (1 - \gamma)^4} + \frac{C^* S t_{\text{mix}}^3 \log T_j}{T_j (1 - \gamma)^3} + \frac{C^* t_{\text{mix}}^2}{T_j (1 - \gamma)^3},
\]
To finish up, combine the preceding bound with (50) to reach
\[
V^* (\rho) - V^* (\rho) \leq \langle \rho, V^* - V_T \rangle \leq \rho, V^* - V_T \rangle \leq \frac{1}{T_K} \sum_{i=1}^{T_K} \langle \rho, V^* - V_i \rangle = \Lambda_k
\]
\[
\leq \left( \frac{C^* S t^2}{T_j (1 - \gamma)^4} \right)^{1/2} \left( \frac{C^* S t^4 \log T_j}{T_j (1 - \gamma)^4} \right)^{1/2}
\]
\[
+ \left( \frac{C^* S t^2}{T_j (1 - \gamma)^3} \right)^{1/2} \left( \frac{C^* t^3 \log T_j}{T_j (1 - \gamma)^3} \right)^{1/2}
\]
\[
+ \left( \frac{C^* S t^2}{T_j (1 - \gamma)^4} \right)^{1/2} \left( \frac{C^* S t_{\text{mix}}^3 \log T_j}{T_j (1 - \gamma)^3} \right)^{1/2}
\]
\[
+ \left( \frac{C^* S t^2}{T_j (1 - \gamma)^4} \right)^{1/2} \left( \frac{C^* t_{\text{mix}}^3 \log T_j}{T_j (1 - \gamma)^3} \right)^{1/2}
\]
\[
+ \left( \frac{C^* S t^2}{T_j (1 - \gamma)^3} \right)^{1/2} \left( \frac{C^* t_{\text{mix}}^2}{T_j (1 - \gamma)^3} \right)^{1/2}
\]
where (i) holds true according to Lemma 6, and (ii) follows due to the monotonicity of \(V_i\) in \(t\). This concludes the proof of Theorem 2.

**Appendix E**

**Auxiliary Lemmas for Theorem 2**

**A. Proof of Lemma 6**

Consider any state-action pair \((s, a) \in S \times A\), and let \(n_i = n_i (s, a)\). For each \(1 \leq i \leq T_k\), define
\[
k_i := \min \left\{ \{0 \leq j < T_k \mid j > k_i-1, (s_j, a_j) = (s, a) \} \right\}, T_k \}
\]
and denote \(k_0 = 0\). Clearly, each \(k_i\) is a stopping time. From the update rule in Algorithm 3, we can write
\[
Q_i (s, a) = \sum_{t=1}^{n_i} \eta_t \left[ T (s, a) + \gamma V_k (s_{k+1}) - \gamma V (s_{k+1}) \right] + \gamma P_{s, a} V - b_i (s, a)
\]
This taken together with the elementary fact 
\[ \sum_{i=1}^{n} \eta_{i}^{n} = 1 \] gives
\[
(Q^{*} - Q_{t})(s, a) = (r + \gamma PV^{*})(s, a) - \sum_{i=1}^{n} \eta_{i}^{n} \left[ r(s, a) + \gamma V_{k_{i}}(s_{k_{i}+1}) - \gamma V_{k_{i}}(s_{k_{i}+1}) + \gamma P_{s,a} V - b_{i}(s, a) \right]
\]
\[
= \gamma \sum_{i=1}^{n} \eta_{i}^{n} (V^{*} - V_{k_{i}})
+ \sum_{i=1}^{n} \eta_{i}^{n} ((P - P_{k_{i}})(V_{k_{i}} - V)) (s, a)
+ \sum_{i=1}^{n} \eta_{i}^{n} b_{i}(s, a). \tag{61}
\]

From the update rules in Algorithms 3-4 as well as Lemma 1, we see that
\[
\sum_{i=1}^{n} \eta_{i}^{n} b_{i}(s, a) \in \left[ \tilde{\beta}_{n}(s, a), 2\tilde{\beta}_{n}(s, a) \right], \tag{62}
\]
where
\[
\tilde{\beta}_{n}(s, a) := C_{b} \sqrt{H_{t} n \left\{ \sigma_{n}^{adv}(s, \pi^{*}(s)) - [\mu_{n}^{adv}(s, \pi^{*}(s))]^{2} \right\}}
+ C_{b} \frac{H_{t}^{3/4}}{n^{3/4} (1 - \gamma)} + C_{b} \frac{H_{t}}{n (1 - \gamma)}
+ C_{b} \sqrt{\frac{l}{\tau} \left\{ \sigma_{ref}(s, a) - [\mu_{ref}(s, a)]^{2} \right\}}
+ C_{b} \frac{1}{(1 - \gamma)} |\tau_{ref}(s, a)|^{3/4} + C_{b} (1 - \gamma) \tau_{ref}(s, a).
\]

From now on, we shall focus on the case where \( a = \pi^{*}(s) \).
The terms \( \alpha_{1} \) and \( \alpha_{2} \) are controlled separately in the following.
- Regarding \( \alpha_{1} \), we first define a filtration \( \mathcal{F}_{i} \) as
\[
\mathcal{F}_{i} := \sigma \left\{ (s_{j}, a_{j}^{D}) : 1 \leq j \leq k_{i}, \cup_{j=1}^{k_{i}} D_{j}^{ref}, \cup_{j=1}^{k_{i}-1} D_{j} \right\}.
\]
Here, \((s_{j}^{ref}, a_{j}^{ref})\) is defined to be the \( i \)-th state-action pair used to update the Q-function estimate (resp. construct the empirical transition kernel) within the \( j \)-th epoch; and we set
\[
D_{j}^{ref} := \left\{ (s_{j}^{ref}, a_{j}^{ref}) : 0 \leq i < T_{j}^{ref} \right\}, \tag{63a}
D_{j} := \left\{ (s_{j}, a_{j}) : 0 \leq i < T_{j} \right\}. \tag{63b}
\]
It is straightforward to check that for any \( 1 \leq \tau \leq T \),
\[
\left\{ 1_{k_{i} < \tau} ((P - P_{k_{i}})(V_{k_{i}} - V)) (s, \pi^{*}(s)) \right\}_{i=1}^{\tau}
\]
is a martingale difference sequence with respect to \( \mathcal{F}_{i} \). Then we can invoke the Freedman inequality to obtain: for any fixed \( s \in S \) and \( \tau \in [T] \), with probability exceeding \( 1 - \delta / S \),
\[
\sum_{i=1}^{\tau} 1_{k_{i} < \tau} \eta_{i}^{n} ((P - P_{k_{i}})(V_{k_{i}} - V)) (s, \pi^{*}(s)) \leq \sqrt{\sum_{i=1}^{\tau} \left( \eta_{i}^{n} \right)^{2} Var_{s, \pi^{*}(s)}(V_{k_{i}} - V) \eta_{i}^{n} \mu_{ref}(s, a) + \frac{H_{t}}{(1 - \gamma) \tau} \sum_{i=1}^{\tau} \eta_{i}^{n} Var_{s, \pi^{*}(s)}(V_{k_{i}} - V)} + \frac{1}{(1 - \gamma)^{4} \tau^{4}}\, H_{t} \cdot \tag{64}
\]
Invoke the union bound to show that with probability at least \( 1 - \delta \), the above inequality holds simultaneously for all \( \tau \in [T] \) and \( s \in S \). Replacing \( \tau \) with \( n = n_{\pi}(s, \pi^{*}(s)) \) yields that, with probability exceeding \( 1 - \delta \),
\[
|\alpha_{1}| \leq \frac{H_{t}}{n (1 - \gamma)^{4}} \sum_{i=1}^{n} \eta_{i}^{n} Var_{s, \pi^{*}(s)}(V_{k_{i}} - V) + \frac{H_{t}}{(1 - \gamma) n} \cdot \tag{65}
\]
holds for all \( s \in S \) and \( t \in [T_{k}] \), where \( n = n_{\pi}(s, \pi^{*}(s)) \).
In addition, the update rules in Algorithm 2 tell us that
\[
\mu_{n}^{adv}(s, a) = \sum_{i=1}^{n} \eta_{i}^{n} \left[ V_{k_{i}}(s_{k_{i}+1}) - V(s_{k_{i}+1}) \right]
= \sum_{i=1}^{n} \eta_{i}^{n} \left( P_{k_{i}}(V_{k_{i}} - V) \right) (s, a)
\]
and
\[
\sigma_{n}^{adv}(s, a) = \sum_{i=1}^{n} \eta_{i}^{n} \left[ V_{k_{i}}(s_{k_{i}+1}) - V(s_{k_{i}+1}) \right]^{2}
= \sum_{i=1}^{n} \eta_{i}^{n} \left( P_{k_{i}}(V_{k_{i}} - V)^{2} \right) (s, a). \tag{65}
\]
Recognizing that
\[
\sum_{i=1}^{n} \eta_{i}^{n} Var_{s,a} (V_{k_{i}} - V)
= \sum_{i=1}^{n} \eta_{i}^{n} P_{s,a} (V_{k_{i}} - V) - \sum_{i=1}^{n} \eta_{i}^{n} \left[ P_{s,a} (V_{k_{i}} - V) \right]^{2},
\]
we can connect \( Var_{s,a} (V_{k_{i}} - V) \) with \( \mu_{n}^{adv} \) and \( \sigma_{n}^{adv} \) as in (66), shown at the bottom of the next page, leaving us with two terms \( \alpha_{1,1} \) and \( \alpha_{1,2} \) to control.
- The first term \( \alpha_{1,1} \) can be bounded by the Azuma-Hoeffding inequality. We can employ similar arguments as used when proving (38) and invoke the Azuma-Hoeffding inequality to show that: with probability exceeding \( 1 - \delta / S \), for all \( s \in S \) and \( t \in [T_{k}] \), it holds that
\[
|\alpha_{1,1}| \leq \sqrt{\frac{H_{t}}{n (1 - \gamma)^{4}}}. \tag{67}
\]
Moving on to the second term $\alpha_{1,2}$, we invoke the identity $\sum_{i=1}^{n} \eta_i^n = 1$ to deduce that

$$\alpha_{1,2} = \left[ \sum_{i=1}^{n} \eta_i^n \left( P_{k_i} \left( V_{k_i} - \overline{V} \right) \right) (s, \pi^*(s)) \right]^2$$

$$- \left( \sum_{i=1}^{n} \eta_i^n \right) \sum_{i=1}^{n} \eta_i^n \left[ P_{s, \pi^*(s)} \left( V_{k_i} - \overline{V} \right) \right]^2$$

$$\leq \left( \sum_{i=1}^{n} \eta_i^n \right) \sum_{i=1}^{n} \eta_i^n \left( (P_{k_i} - P) \left( V_{k_i} - \overline{V} \right) \right) (s, \pi^*(s))$$

$$\cdot \left[ \sum_{i=1}^{n} \eta_i^n \left( (P_{k_i} + P) \left( V_{k_i} - \overline{V} \right) \right) (s, \pi^*(s)) \right]$$

$$\leq \frac{1}{1 - \gamma} \sum_{i=1}^{n} \eta_i^n \left( (P_{k_i} - P) \left( V_{k_i} - \overline{V} \right) \right) (s, \pi^*(s))$$

$$\leq \sqrt{\frac{H_T}{n (1 - \gamma)^2}}.$$ 

Here, (i) arises from the Cauchy-Schwarz inequality; (ii) follows from the fact that $0 \leq V_{k_i} - \overline{V} \leq 1/(1 - \gamma)$ and the identity $\sum_{i=1}^{n} \eta_i^n = 1$; and (iii) follows by repeating the argument used to establish (38) and invoking the Azuma-Hoeffding inequality (which we omit here for the sake of brevity).

With the preceding bounds in place, we conclude that with probability exceeding $1 - O(\delta)$,

$$\sum_{i=1}^{n} \eta_i^n \text{Var}_{s, \pi^*(s)} \left( V_{k_i} - \overline{V} \right) \leq \frac{H_T}{n (1 - \gamma)^2}.$$ 

holds for all $s \in \mathcal{S}$ and $t \in [T_k]$. Putting the above results together and using the fact $\sigma^{adv}_n(s, \pi^*(s)) \geq \left( \mu_n^{adv}(s, \pi^*(s)) \right)^2$ (due to Jensen’s inequality) reveal that with probability exceeding $1 - O(\delta)$,

$$|\alpha_1| \lesssim \sqrt{\frac{H_T}{n} \sum_{i=1}^{n} \eta_i^n \text{Var}_{s, \pi^*(s)} (V_{k_i} - \overline{V}) + \frac{H_T}{n (1 - \gamma)^2}}$$

$$\lesssim \sqrt{\frac{H_T}{n} \left( \sigma^{adv}(s, \pi^*(s)) - \left( \mu_n^{adv}(s, \pi^*(s)) \right)^2 \right) + \frac{H_T^{3/4} \gamma^{3/4}}{n^{3/4} (1 - \gamma) + \frac{H_T}{n (1 - \gamma)}}}$$

holds for all $s \in \mathcal{S}$ and $t \in [T_k]$.

Regarding $\alpha_{2}$, we first recall that $n^{ref}(s, a)$ denotes the number of visit to $(s, a)$ among the samples used to compute $P$. Let $k_0 = -1$, and for each $1 \leq i \leq T^{ref}_k$, define

$$k_i := \min\{\{0 \leq k < T^{ref}_k \mid k > k_{i-1}, (s_k, a_k) = (s, a)\}, T^{ref}_k\}.$$ 

Akin to how we establish (64), we can use the Freedman inequality to show that: for any fixed $s \in \mathcal{S}$, with probability exceeding $1 - \delta/\mathcal{S}$,

$$|\alpha_2| = \gamma \sqrt{\left( P - \overline{P} \right) \overline{V}} \left( s, \pi^*(s) \right) + \gamma \sqrt{\frac{1}{n^{ref}(s, \pi^*(s))} \sum_{i=0}^{T^{ref}_k} \left( P - P^{ref}_{i, a}(s, a) \right) \left( s, \pi^*(s) \right) - 1} \left( \left\{ \text{ref} : a^{ref} = (s, \pi^*(s)) \right\} \right)$$

$$\lesssim \sqrt{\frac{\text{Var}_{s, \pi^*(s)} (V)}{n^{ref}(s, \pi^*(s))} - 1} + \frac{t}{(1 - \gamma) n^{ref}(s, \pi^*(s))}.$$ 

(66)
Here, the first line results from the identity \( \sum_{i=1}^{n} \eta_i^n = 1 \). It follows from the update rule in Algorithm 2 that

\[
\mu_{\text{ref}}(s, a) = \frac{1}{n_{\text{ref}}(s, a)} \sum_{i=1}^{n_{\text{ref}}(s, a)} \nabla(s_{k_i+1})
\]

\[
= \frac{1}{n_{\text{ref}}(s, a)} \sum_{i=1}^{n_{\text{ref}}(s, a)} (P_{k_i, \nabla})(s, a),
\]

and

\[
\sigma_{\text{ref}}(s, a) = \frac{1}{n_{\text{ref}}(s, a)} \sum_{i=1}^{n_{\text{ref}}(s, a)} \nabla^2(s_{k_i+1})
\]

\[
= \frac{1}{n_{\text{ref}}(s, a)} \sum_{i=1}^{n_{\text{ref}}(s, a)} (P_{k_i, \nabla^2})(s, a),
\]

allowing us to deduce (68), shown at the bottom of the page. Using the similar argument in proving (38) and the Azuma-Hoeffding inequality, we can show that with probability exceeding \( 1 - O(\delta) \),

\[
\alpha_{2,1} \lesssim \frac{1}{(1 - \gamma)^2} \sqrt{\frac{l}{n_{\text{ref}}(s, a)}}.
\]

The second term \( \alpha_{2,2} \) can be bounded by

\[
\alpha_{2,2} = \left| \frac{1}{n_{\text{ref}}(s, \pi^*)(s)} \sum_{i=1}^{n_{\text{ref}}(s, \pi^*)(s)} ((P_{k_i} - P) \nabla)(s, \pi^*(s)) \right|
\]

\[
= \frac{1}{n_{\text{ref}}(s, \pi^*)(s)} \sum_{i=1}^{n_{\text{ref}}(s, \pi^*)(s)} ((P_{k_i} + P) \nabla)(s, \pi^*(s))
\]

\[
\lesssim \frac{2}{1 - \gamma} \frac{1}{n_{\text{ref}}(s, \pi^*)(s)} \sum_{i=1}^{n_{\text{ref}}(s, \pi^*)(s)} ((P_{k_i} - P) \nabla)(s, \pi^*(s))
\]

\[
\lesssim \frac{1}{(1 - \gamma)^2} \sqrt{\frac{l}{n_{\text{ref}}(s, \pi^*)(s)}}.
\]

Here, the penultimate line follows from the fact that \( \frac{1}{\nabla(s)} \leq 1/(1 - \gamma) \) for all \( s \in S \), whereas the last line can be proved by using the similar argument used to establish (38) and invoking the Azuma-Hoeffding inequality. These bounds taken collectively allow us to derive

\[
\text{Var}_{s, \pi^*}(\nabla) = \sigma^2_{\text{ref}}(s, \pi^*(s)) - [\mu_{\text{ref}}(s, \pi^*(s))]^2 + O(\alpha_{2,1} + \alpha_{2,2})
\]

\[
= \sigma_{\text{ref}}^2(s, \pi^*(s)) - [\mu_{\text{ref}}(s, \pi^*(s))]^2 + O\left( \frac{1}{(1 - \gamma)^2} \sqrt{\frac{l}{n_{\text{ref}}(s, \pi^*(s))}} \right).
\]

Consequently, it is immediately seen that: with probability exceeding \( 1 - O(\delta) \),

\[
\left| \alpha_2 \right| \lesssim \sqrt{\frac{l}{n_{\text{ref}}(s, \pi^*(s))}} \left\{ \sigma_{\text{ref}}^2(s, \pi^*(s)) - [\mu_{\text{ref}}(s, \pi^*(s))]^2 \right\}
\]

\[
+ \left( \frac{l}{1 - \gamma} \right)^{3/4} + \frac{l}{(1 - \gamma) n_{\text{ref}}(s, \pi^*(s))}
\]

holds simultaneously for all \( s \in S \).

With the above bounds on \( \alpha_1 \) and \( \alpha_2 \) in place, we can take these together with (62) to obtain

\[
0 \leq \sum_{i=1}^{n} \eta_i^n b_i(s, \pi^*(s)) + \alpha_1 + \alpha_2
\]

\[
\leq 3\beta_n(s, \pi^*(s)) = \beta_n(s, \pi^*(s)),
\]

with the proviso that \( C_b > 0 \) is sufficiently large. Substitution into (61) then gives: with probability exceeding \( 1 - O(\delta) \),

\[
(Q^* - Q_t)(s, \pi^*(s))
\]

\[
\leq \gamma \sum_{i=1}^{n} \eta_i^n P_{s, \pi^*(s)}(V^* - V_{k_i}) + \beta_n(s, \pi^*(s))
\]

holds for all \( s \in S \) and \( t \in [T_k] \).

The second part of the lemma — namely, \( V_t(s) \leq V^*(s) \) for all \( s \in S \) and \( t \in [T_k] \) — can be proved in a way similar to the proof of the second part of Lemma 2. We omit it here for brevity.

**B. Proof of Lemma 7**

In view of (65), we can deduce that

\[
\sigma_{\text{ref}}^2(n_{\text{ref}})(s, \pi^*(s)) = \sum_{i=1}^{n} \eta_i^n P_{s, \pi^*(s)}(V_{k_i} - \nabla)^2(s, \pi^*(s))
\]

\[
= \sum_{i=1}^{n} \eta_i^n P_{s, \pi^*(s)}(V_{k_i} - \nabla)^2.
\]
This leaves us with two terms decreasing in $t$ and $V \leq V_t \leq V^*$, while the last inequality invokes the upper bound on $\alpha_{1,1}$ (cf. (67)) derived in Lemma 6. In addition, we observe that

$$
\sigma^2(s, \pi^*(s)) - [\mu^2(s, \pi^*(s))]
= \text{Var}_{s, \pi^*(s)}(V) + O \left( \frac{1}{(1-\gamma)^2} \sqrt{\frac{t}{n \rho^2(s, \pi^*(s))}} \right),
$$

which follows directly from (69).

Next, we turn to bounding the sum $\sum_{s,a} d^*_p(s, a) \text{Var}_{s,a}(V)$, which can be decomposed into

$$
\sum_{s,a} d^*_p(s, a) \text{Var}_{s,a}(V) = \sum_{s \in S, a \in A} d^*_p(s, a) \text{Var}_{s,a}(V^*)
+ \sum_{s,a} d^*_p(s, a) \left[ \text{Var}_{s,a}(V) - \text{Var}_{s,a}(V^*) \right].
$$

(70)

This leaves us with two terms $\alpha_1$ and $\alpha_2$ to control.

- With regards to $\alpha_1$, we first define a vector $v = [v_s]_{s \in S} \in \mathbb{R}^S$ obeying

$$
v_s := \text{Var}_{s, \pi^*(s)}(V^*) \quad \text{for all } s \in S,
$$

which clearly satisfies

$$
v = P_{\pi^*} [V^* \circ V^*] - (P_{\pi^*} V^* \circ (P_{\pi^*} V^*))
= P_{\pi^*} (V^* \circ V^*) - \frac{1}{\gamma^2} (r - V^*) \circ (r - V^*)
= P_{\pi^*} (V^* \circ V^*) - \frac{1}{\gamma^2} r \circ r - \frac{1}{\gamma^2} V^* \circ V^* + 2 V^* \circ r
\leq \frac{1}{\gamma^2} (\gamma^2 P_{\pi^*} - I) (V^* \circ V^*) + 2 V^* \circ r.
$$

(71)

Here, the second identity follows from the Bellman optimality equation $V^* = r + \gamma P_{\pi^*} V^*$. Recognizing that $d^*_p(s, a) = d^*_p(s, a) 1\{a = \pi^*(s)\}$ and $d^*_p = (1-\gamma)\rho(I - \gamma P_{\pi^*})^{-1}$, we obtain (72), shown at the bottom of the next page. In (72), (i) follows from (71); (ii) relies on the triangle inequality as well as the Bellman optimality equation $V^* = (I - \gamma P_{\pi^*})^{-1} r$; and (iii) arises from the property $0 \leq V^*(s) \leq 1/(1-\gamma)$ for all $s \in S$ as well as the assumption that $\gamma \leq 1/2$.

- Regarding $\alpha_2$, we make the observation that

$$
\alpha_2 = \sum_{s \in S, a \in A} d^*_p(s, a) \left\{ P_{s,a} V^2 - [P_{s,a} V]^2 - P_{s,a} (V^2) \right\}
+ [P_{s,a} V^2]^2
$$

where the first identity holds since $d^*_p(s, a) = d^*_p(s, a) 1\{a = \pi^*(s)\}$, and the second line invokes (74).

(73)
C. Proof of Lemma 8

Recall that

\[
\bar{\rho} := \frac{d^*_\rho - (1 - \gamma) \rho}{\gamma},
\]

which is clearly also a probability vector. To prove the lemma, we find it helpful to introduce the following occupancy distribution induced by \(\bar{\rho}\):

\[
d^*_\rho(s) := (1 - \gamma) \sum_{i=0}^{\infty} \gamma^i \mathbb{P}(s_t = s | \pi^*, s_0 \sim \bar{\rho}).
\]

Repeating the argument used to establish (24), we can easily see that: for any vector \(V \in \mathbb{R}^d\) with non-negative entries, it holds that

\[
\sum_{j=0}^{\infty} \left[ \gamma \left( 1 + \frac{1}{H} \right)^j \right] \langle \bar{\rho} P^*_\pi, V \rangle \leq \frac{1}{1 - \gamma} \langle d^*_\rho, V \rangle + \frac{\delta}{ST^4 (1 - \gamma)} \|V\|_\infty.
\]

Consequently, it boils down to analyzing the distribution \(d^*_\rho\).

For any integer \(K \geq 0\), employ the identity

\[
d^*_\rho = \rho \sum_{i=0}^{\infty} \gamma^i (P^*_\pi)^i
\]

to deduce (76), shown at the bottom of the next page. In (76), (i) and (ii) make use of the lemma, we find it helpful to introduce the following occupancy

\[
d^*_\rho(s) := (1 - \gamma) \sum_{i=0}^{\infty} \gamma^i (P^*_\pi)^i
\]

with 1 the all-one vector, where the second line holds since \(\rho(P^*_\pi)^i\) remains a probability vector (and hence \(\rho(P^*_\pi)^i\)1 = 1). Here, the last line follows from our assumption that \(\gamma \geq 1/2\) and the fact that

\[
\gamma^K = e^{K \log(1 - (1 - \gamma))} \leq e^{-K(1 - \gamma)} \leq e^{-C_K \log(\delta ST/\delta)}
\]

provided that \(C_K \geq 5\).

We are now ready to establish the claim of this lemma. Substituting the bounds (77) and (78) into (75) leads to

\[
\langle d^*_\rho, V \rangle \lesssim \frac{\delta}{ST^4 (1 - \gamma)} \|V\|_\infty.
\]

As a result, one can readily conclude that

\[
\sum_{j=0}^{\infty} \left[ \gamma \left( 1 + \frac{1}{H} \right)^j \right] \langle \bar{\rho} P^*_\pi, V \rangle \leq \frac{1}{1 - \gamma} \langle d^*_\rho, V \rangle \|V\|_\infty.
\]

APPENDIX F

ANALYSIS FOR THE MINIMAX LOWER BOUND IN THEOREM 3

Without loss of generality, we assume throughout the proof that \(S\) is an odd number.

Construction of Hard MDP Instances: For any vector \(\theta = [\theta_s]_{1 \leq s \leq S} \in \mathbb{R}^S\) with \(\|\theta\|_\infty \leq 1/2\), define an MDP \(\mathcal{M}_\theta = \{\hat{S}, \hat{A}, \gamma, P_\theta, r\}\) parameterized by \(\theta\) with the state

\[
\alpha_1 = \sum_{s \in S} d^*_\rho(s) \text{Var}_{s, \pi^*(s)}(V^*) - \langle d^*_\rho, v \rangle = (1 - \gamma) \rho (I - \gamma P^*_\pi)^{-1} v
\]

\[
\|(I - \gamma P^*_\pi)^{-1} v\|_\infty \geq \left( \frac{1 - \gamma}{\gamma} \right) \|\rho\|_1 \|v\|_\infty - \frac{1 - \gamma}{\gamma^2} \|v\|_\infty \|r\|_\infty
\]

\[
\|((I - \gamma P^*_\pi)^{-1} (V^* \circ (I + \gamma (I - P^*_\pi)) V^*))\|_\infty \leq \left( \frac{1 - \gamma}{\gamma^2} \right) \|\rho\|_1 \|v\|_\infty \|r\|_\infty
\]

\[
\leq \left( \frac{1 - \gamma}{\gamma^2} \right) \|((I - \gamma P^*_\pi)^{-1} (V^* \circ (I + \gamma (I - P^*_\pi)) V^*))\|_\infty + \frac{1 - \gamma}{\gamma} \|V^*\|_\infty + 2 (1 - \gamma) \|V^*\|_\infty^2
\]

\[
\leq \left( \frac{1 - \gamma}{\gamma^2} \right) \frac{1}{1 - \gamma} \|V^*\|_\infty^2 + \frac{1 - \gamma}{\gamma} \|V^*\|_\infty^2 + 2 (1 - \gamma) \|V^*\|_\infty^2 \leq \frac{8}{1 - \gamma}.
\]
space \( \mathcal{S} = \{0, \pm 1, \ldots, \pm \frac{S-1}{2}\} \) and the action space \( \mathcal{A} = \{\pm 1\} \). Several key elements are constructed as follows.

- We first initialize the state distribution as
  \[
  \rho(s) = \left(1 - \frac{1}{\tau_{\text{mix}}}\right) \mathbb{1}(s = 0) + \frac{1}{(S-1)\tau_{\text{mix}}} \mathbb{1}(s \neq 0)
  \]
  for all \( s \in \mathcal{S} \), where \( \tau_{\text{mix}} \) is defined to be
  \[
  \tau_{\text{mix}} = \frac{16c_2}{(1 - \gamma) \varepsilon}.
  \]
  It is self-evident that as long as \( c_1 \leq 32c_2 \), we have \( \tau_{\text{mix}} \geq 2 \) and hence \( \rho \) is well-defined.
- The transition probability kernel is constructed such that
  \[
  P_\theta(s' | s, a) = \left(1 - \frac{1}{\tau_{\text{mix}}}\right) \left[\left(\frac{1}{2} + \theta s a\right) \mathbb{1}(s' = s) \right.
  + \left(\frac{1}{2} - \theta s a\right) \mathbb{1}(s' = -s) \right] + \frac{1}{\tau_{\text{mix}}} \rho(s')
  \]
  for any \( (s, a, s') \in \mathcal{S} \times \mathcal{A} \times \mathcal{S} \).
- The reward function is taken to be
  \[
  r(s, a) = \begin{cases} 
  1, & \text{if } s > 0; \\
  0, & \text{if } s \leq 0.
  \end{cases}
  \]
- The behavior policy is chosen to be
  \[
  \pi_b(a | s) = \frac{1}{2}, \quad \forall (s, a) \in \mathcal{S} \times \mathcal{A}.
  \]
- Furthermore, we shall define
  \[
  \Theta := \left\{ \theta \in \mathbb{R}^S : \theta_s \in \{\pm \frac{1}{2}\} \text{ for } s > 0, \text{ and } \theta_s = 0 \text{ for } s \leq 0 \right\},
  \]
  and we consider a class of MDP given by \( \mathcal{M}_\theta : \theta \in \Theta \).

In what follows, we shall also let \( \mathcal{U} \) represent the uniform distribution over \( \Theta \).

### Useful Properties About the Constructed MDP

Next, for any \( \theta \in \Theta \), we gather a couple of basic properties about \( \mathcal{M}_\theta \) and the Markov chain induced by the behavior policy \( \pi_b \).
- The stationary distribution \( \mu_b \) of the Markov chain induced by \( \pi_b \) is given by
  \[
  \mu_b(s, a) = \rho(s) \pi_b(a | s) = \frac{1}{2} \rho(s).
  \]
  for all \( (s, a) \). The mixing time of this Markov chain is at most \( 2t_{\text{mix}} \), since it is clear that
  \[
  d_{TV} \left( P_\theta^t \left( \cdot \mid s_0, a_0 \right), \mu_b \right) \leq \left(1 - \frac{1}{t_{\text{mix}}}\right)^t \leq \frac{1}{4}
  \]
  for all \( (s_0, a_0) \in \mathcal{S} \times \mathcal{A} \), as long as \( t \geq 2t_{\text{mix}} \).
- For any policy \( \pi \), it can be verified that
  \[
  d_{\rho}^\pi(s) \leq 3 \rho(s)
  \]
  for any \( (s, a) \in \mathcal{S} \times \mathcal{A} \). The proof of (80) is deferred to Appendix F-A. This immediately gives
  \[
  C^* = \sup_{(s, a) \in \mathcal{S} \times \mathcal{A}} d_{\rho}^\pi(s) \leq 2 \sup_{(s, a) \in \mathcal{S} \times \mathcal{A}} d_{\rho}^\pi(s) \leq 3,
  \]
  where (i) follows from (79), and (ii) utilizes (80).
- The optimal policy \( \pi_\theta^* \) is given by
  \[
  \pi_\theta^*(s) = \text{sign}(\theta_s), \quad \forall s > 0,
  \]
  and \( \pi_\theta^*(s) \) can be either \( 1 \) or \( -1 \) for \( s \leq 0 \). In addition, for any \( s > 0 \) and any policy \( \pi \) that is independent of \( \theta_s \), we can show that
  \[
  \mathbb{E}_{\mathcal{M}_\theta, \theta \sim \mathcal{U}} [V_\theta^*(s) - V^\pi(s)] \geq 0
  \]
  and \( \pi_\theta^*(s) \) can be either \( 1 \) or \( -1 \) for \( s \leq 0 \). In addition, for any \( s > 0 \) and any policy \( \pi \) that is independent of \( \theta_s \), we can show that
  \[
  \mathbb{E}_{\mathcal{M}_\theta, \theta \sim \mathcal{U}} [V_\theta^*(s) - V^\pi(s)] \geq \frac{1}{35} (1 - \gamma).
  \]

The proof of (81) and (82) can be found in Appendix F-B.

### Proof of the Claimed Lower Bound

Let
\[
X_1, \ldots, X_T \overset{\text{i.i.d.}}{\sim} \text{Bernoulli}(1/\tau_{\text{mix}})
\]

Then, we have
\[
\begin{align*}
  \mathbb{E}_{\mathcal{M}_\theta} [V_\theta^*(s) - V^\pi(s)] & \geq \frac{1}{35} (1 - \gamma).
\end{align*}
\]
and
\[ Y_1, \ldots, Y_T \overset{i.i.d.}{\sim} \text{Bernoulli}(1/\tau_{mix}) \]
be two independent sequences of Bernoulli random variables. Let \( S_T \) be the number of different state pairs \( \{\pm s\} \) visited by the sample trajectory. From the construction of the Markov chain, we know that \( S_T \) is stochastically dominated by \( 1 + \sum_{t=1}^{T} X_t Y_t \). In view of this, we have
\[
E[S_T] \leq E \left[ 1 + \sum_{t=1}^{T} X_t Y_t \right] = 1 + \frac{T}{\tau_{mix}} S_{\frac{1}{2}} \leq 1 + \frac{2S}{\tau_{mix}} \leq \frac{S}{\gamma},
\]
where the last relation holds since \( \tau_{mix} = 16(\frac{1}{1-\gamma})^2 \) and \( S \geq 16 \). This implies that with probability at least 0.5, \( S_T \leq S/4 \). Then for any estimator \( \pi \), with probability at least 0.5 we have
\[
\max_{\mathcal{M}_a, \theta \in \Theta} V^*(\rho) - V^\pi(\rho) \geq \sum_{s \in S} \rho(s) \mathbb{E} \left[ V^*(\rho) - V^\pi(\rho) \right] \geq \sum_{s \in S} \rho(s) \mathbb{E}_{\mathcal{M}_a, \theta \sim \mathcal{U}} \left[ V^*(s) - V^\pi(s) \right] \geq \frac{S - 1}{2} S_{\frac{1}{2}} \left( \frac{1}{S-1} \right) \gamma_{\frac{1}{2}} \geq \frac{8400c_2}{2}.
\]
Here, (i) holds since there are at least \((S-1)/2 - S_T\) states \( s \) satisfying \( s > 0 \) and the state pair \( \{\pm s\} \) is not visited by the sample trajectory. For any such state \( s \), any estimator based on the observed sample trajectory is independent of \( \theta \). Then (i) follows from (82). In addition, (ii) holds as long as \( S_T \leq S/4 \), \( S \geq 16 \) and \( \gamma \geq 1/2 \). By replacing \( \varepsilon \) with \( 4800c_2 \varepsilon \), we arrive at the desired lower bound.

### A. Proof of Equation (80)

Let \( P_\theta^\pi : S \to S \) be the probability transition kernel defined as
\[
P_\theta^\pi(s' | s) = \sum_{a \in A} P_\theta(s' | s, a) \pi(a | s), \quad \forall (s, a) \in S \times A.
\]
For any policy \( \pi \) and any \( \nu \in \Delta(S) \) satisfying \( \nu(s) + \nu(-s) = \rho(s) + \rho(-s) = 2\rho(s) \) for all \( s \in S \), we have (83), shown at the bottom of the page, for any \( s' \in S \). In (83) the last relation follows from \( \nu(s) + \nu(-s) = 2\rho(s) \). Therefore for any \( s \in S \), we have
\[
\left| \nu(P_\theta^\pi)(s') - \rho(s) \right| \leq \frac{1}{2} \| \theta \|_{\infty} \nu(s) + \frac{1}{2} \| \theta \|_{\infty} \nu(-s) = \| \theta \|_{\infty} \rho(s).
\]
We can then employ standard induction arguments to verify that for any \( n \geq 0 \),
\[
\left[ \rho(P_\theta^\pi)^n \right](s) + \left[ \rho(P_\theta^\pi)^n \right](-s) = 2\rho(s).
\]
This immediately gives
\[
d_\rho^\pi(s) = (1 - \gamma) \sum_{j=0}^{\infty} \gamma^j \left[ \rho(P_\theta^\pi)^j \right](s)
\]
\[
= \rho(s) + (1 - \gamma) \sum_{j=0}^{\infty} \gamma^j \left[ \rho(P_\theta^\pi)^j \right] - \rho(s)
\]
\[
\leq \rho(s) + (1 - \gamma) \sum_{j=0}^{\infty} \gamma^j \| \theta \|_{\infty} \rho(s)
\]
\[
= \left( 1 + \| \theta \|_{\infty} \right) \rho(s) \leq \frac{3}{2} \rho(s).
\]

### B. Proof of Equations (81) and (82)

For any policy \( \pi \), the Bellman equations assert that
\[
Q^\pi(s, a) = r(s, a) + \gamma \left( \frac{1}{t_{mix}} V^\pi(\rho) + \frac{1}{t_{mix}} \left[ \left( 1 + \theta_s a \right) V^\pi(s) + \left( 1 - \theta_s a \right) V^\pi(-s) \right] \right)
\]
and
\[
V^\pi(s) = \pi(1 | s) Q^\pi(s, 1) + \pi(-1 | s) Q^\pi(s, -1)
\]
for any \( (s, a) \in S \times A \). For any given \( s > 0 \), denote by \( x = V^\pi(s) \) and \( y = V^\pi(-s) \). Since \( \theta_s = 0 \), we have \( Q^\pi(-s, 1) = Q^\pi(s, -1) \). Then the above Bellman equations give (84), shown at the bottom of the next page. Solving the system of equations (84) with respect to \( x \) and \( y \) gives (85), shown at the bottom of the next page. Similarly, we can also derive
\[
V^\pi(0) = \frac{1}{1 - \gamma} \left( \frac{1}{t_{mix}} \right) \gamma^j V^\pi(\rho).
\]
Then it boils down to determining $V^\pi(\rho)$, for which we have

$$V^\pi(\rho) = \mathbb{E}_{s \sim \rho} [V^\pi(s)]$$

$$= \left(1 - \frac{1}{\tau_{mix}}\right) V^\pi(0) + \sum_{s \neq 0} \frac{1}{(S-1)\tau_{mix}} V^\pi(s)$$

$$= \frac{1 - \frac{1}{\tau_{mix}}}{1 - \gamma (1 - \frac{1}{\tau_{mix}})} \frac{\gamma}{t_{mix}} V^\pi(\rho) + \sum_{s > 0} \frac{1}{(S-1)\tau_{mix}} \frac{1}{1 - \gamma (1 - \frac{1}{\tau_{mix}})} V^\pi(s)$$

This further leads to (86), shown at the bottom of the page. By taking together (85) and (86), one can check that the optimal policy $\pi^*_\theta$ is given by

$$\pi^*_\theta(s) = \text{sign}(\theta_s)$$

for any $s > 0$. The choice of $\pi^*_\theta(s)$ for $s \leq 0$ does not affect the value function and can be chosen arbitrarily.

Let

$$C_0 := \frac{2 - \gamma (1 - \frac{1}{\tau_{mix}})}{2 - 2\gamma (1 - \frac{1}{\tau_{mix}})} = \frac{1}{2} + \frac{1}{2} \frac{1}{1 - \gamma}$$

$$\geq \frac{5}{11 (1 - \gamma)}.$$

(87)

where the last step holds since $t_{mix} \geq 10/(1 - \gamma)$. Then (85) implies that

$$V^\pi(s) = \frac{C_0}{1 - \theta_s (1 - \frac{1}{\tau_{mix}})} (2\pi (1 | s) - 1) + R^\pi$$

where

$$0 \leq R^\pi \leq \frac{1}{(1 - \gamma)^2 t_{mix}}.$$

It is straightforward to compute

$$\mathbb{E}_{\mathcal{M}_0; \theta \sim \mathcal{U}} [V^\pi(\rho)] = \frac{C_0}{1 - \frac{1}{2} \gamma (1 - \frac{1}{\tau_{mix}})} + \mathbb{E}_{\mathcal{M}_0; \theta \sim \mathcal{U}} [R^\pi(\rho)]$$

For any policy $\pi$ that is independent of $\theta_s$, we can also compute

$$\mathbb{E}_{\mathcal{M}_0; \theta \sim \mathcal{U}} [V^\pi(s)]$$

$$= \frac{1}{2} \frac{1 - \frac{1}{2}\gamma (1 - \frac{1}{\tau_{mix}})}{C_0} (2\pi (1 | s) - 1) + \mathbb{E}_{\mathcal{M}_0; \theta \sim \mathcal{U}} [R^\pi(\rho)]$$

$$\leq \frac{1}{2} \frac{1 - \frac{1}{2}\gamma (1 - \frac{1}{\tau_{mix}})}{C_0} (2\pi (1 | s) - 1)^2 + \mathbb{E}_{\mathcal{M}_0; \theta \sim \mathcal{U}} [R^\pi(\rho)].$$

Therefore, we can conclude that

$$\mathbb{E}_{\mathcal{M}_0; \theta \sim \mathcal{U}} [V^\pi(\rho)]$$

$$\geq C_0 \frac{1 - \frac{1}{2}\gamma (1 - \frac{1}{\tau_{mix}})}{1 - \frac{1}{2}\gamma (1 - \frac{1}{\tau_{mix}})} + \mathbb{E}_{\mathcal{M}_0; \theta \sim \mathcal{U}} [R^\pi(\rho)]$$

$$\geq \frac{1}{341 (1 - \gamma)} - \frac{1}{(1 - \gamma)^2 \tau_{mix}} \geq \frac{1}{35 (1 - \gamma)}.$$
where the last two relations follow from (87) and the assumptions that $\gamma \leq 1/2$ and $t_{\text{mix}} \geq 10/(1 - \gamma)$.

ACKNOWLEDGMENT

Part of this work was done while Yuling Yan, Gen Li and Yuxin Chen were visiting the Simons Institute for the Theory of Computing.

He is currently an Associate Professor of statistics and data science with The Wharton School, University of Pennsylvania. Prior to joining the University of Pennsylvania, he was an Assistant Professor of electrical and computer engineering with Princeton University from 2017 to 2021. He was a Post-Doctoral Scholar with the Department of Statistics, Stanford University, from 2015 to 2017. His research interests include high-dimensional data analysis, convex and non-convex optimization, reinforcement learning, statistical learning, statistical signal processing, and information theory. He has received the Alfred P. Sloan Research Fellowship, the Google Research Scholar Award, the Princeton Graduate Mentoring Award, the AFOSR Young Investigator Award, the ARO Young Investigator Award, the ICCM Best Paper Award (Gold Medal), and the Princeton SEAS Junior Faculty Award, and was selected as the Finalist for the Best Paper Prize for Young Researchers in Continuous Optimization 2019.

Jiangning Fan received the Ph.D. degree from the University of California at Berkeley. He has been appointed as an Assistant Professor, an Associate Professor, and a Full Professor with the University of North Carolina at Chapel Hill (1989–2003), a Professor with the University of California at Los Angeles (1997–2000), a Professor and the Chair with The Chinese University of Hong Kong (2000–2003), and a Professor with Princeton University since 2003. He is currently a Frederick L. Moore Professor of finance, a Professor of operations research and financial engineering, the former Chair of the Department of Operations Research and Financial Engineering, and the Director of the Committee of Statistical Studies, Princeton University, where he directs both financial econometrics and statistics laboratories. His research interests include high-dimensional statistics, data science, machine learning, financial econometrics, and computational biology. He is a fellow of the American Association for the Advancement of Science, the Institute of Mathematical Statistics, the American Statistical Association, and the Society of Financial Econometrics. His published work on statistics, machine learning, economics, finance, and computational biology has been recognized by the 2000 COPSS Presidents’ Award, the 2007 Morningside Gold Medal of Applied Mathematics, the Guggenheim Fellow in 2009, the Pao-Lu Hsu Prize in 2013, the Royal Statistical Society Guy Medal in Silver in 2014, the Noether Distinguished Scholar Award in 2018, the Le Cam Award and Lecture in 2021, and election to Academician of Academia Sinica. He was the past President of the Institute of Mathematical Statistics and the International Chinese Statistical Association. He is the Joint Editor of Journal of the American Statistical Association and was the Co-Editor of The Annals of Statistics, Probability Theory and Related Fields, The Econometrics Journal, Journal of Econometrics, and Journal of Business and Economics Statistics.
