By using the analogy between optics and quantum mechanics, we obtain the Snell law for the planar motion of quantum particles in the presence of quaternionic potentials. © 2013 AIP Publishing LLC. [http://dx.doi.org/10.1063/1.4853895]

I. INTRODUCTION

Analogies between quantum mechanics\textsuperscript{1,2} and optics\textsuperscript{3,4} are well known. The possibility to propose optical experiments to study the fascinating behavior of quantum mechanical system is a subject of great interest in literature.\textsuperscript{5,6} The recent progress\textsuperscript{7–16} in looking for quantitative and qualitative differences between complex and quaternionic quantum mechanics\textsuperscript{17} surely have contributed to make the subject more useful to and accessible over the worldwide community of scientists interested in testing the existence of quaternionic potentials. Stimulated by the analogy between quantum mechanics and optics, in this paper we propose a quantum mechanical study of the planar motion in the presence of a quaternionic potential which leads to a new Snell law.

In Sec. II, by considering the ordinary Schrödinger equation and complex wave functions, we obtain the standard Snell law by using the planar motion in the presence of complex potentials. In Sec. III, we introduce the quaternionic Schrödinger equation and calculate, for quaternionic wave functions, the new Snell law. In Sec. II, we obtain the reflection coefficient for the planar motion in presence of quaternionic potentials and compare the complex case with the pure quaternionic case. Section V contains a discussion of the results, a proposal for further studies and, finally, our conclusions.

II. COMPLEX QUANTUM MECHANICS AND SNELL LAW

Consider an optical beam moving from a dielectric medium with refractive index $n_1$ to a second dielectric medium of refractive index $n_2 < n_1$. If the incoming beam forms an angle $\theta$ with respect to the perpendicular direction to the stratification, the beam, for incidence angle $\theta < \theta_c = \arcsin[n_2/n_1]$ will be transmitted in the second medium and will be deflected forming an angle $\phi$ given by the well-known Snell law,\textsuperscript{3,4}

$$\sin \theta = n \sin \phi,$$

(1)

where $n = n_2/n_1$. For $\theta > \theta_c$, we have total reflection.

The analogy between optics and quantum mechanics allows to obtain this fascinating law by analyzing the reflected and refracted waves for the planar $(y, z)$ motion of a quantum mechanical particle in the presence of a stratified potential,\textsuperscript{18,19}

$$V_1(z_s) = \begin{cases} 0 & \text{for } z_s < d_s \\ V_1 & \text{for } z_s > d_s \end{cases},$$

PLANAR MOTION IN THE PRESENCE OF COMPLEX AND QUATERNIONIC POTENTIALS

FIG. 1. Planar motion in the presence of complex (a) and pure quaternionic (b) potentials. For a given incidence angle, complex potentials present a deflection greater than pure quaternionic potentials. As a consequence, the critical angle is greater for pure quaternionic than for complex potentials.

whose discontinuity is at a distance \( d_s \) from the particle source along the \( z_s \)-stratification axis forming with the incident direction \( z \) an angle \( \theta \) (see Fig. 1(a)),

\[
\begin{pmatrix}
y_s \\
z_s
\end{pmatrix} = \begin{pmatrix}
\cos \theta & \sin \theta \\
-\sin \theta & \cos \theta
\end{pmatrix}
\begin{pmatrix}
y \\
z
\end{pmatrix}.
\]

The solution of the Schrödinger equation for \( z_s < d_s \) (region I) is given by

\[
\psi_I(y_s, z_s) = \psi_{\text{inc}}(y_s, z_s) + r \psi_{\text{ref}}(y_s, z_s),
\]

where \( r \) is the reflection amplitude,

\[
r = \frac{p_{z_s} - q_{z_s}}{p_{z_s} + q_{z_s}} \exp\left[ 2 i \frac{p_{z_s} d_s}{\hbar} \right],
\]

\( \psi_{\text{inc}} \) the incoming wave moving along the \( z \)-axis,

\[
\psi_{\text{inc}}(y_s, z_s) = \exp\left[ i \frac{p z}{\hbar} \right] = \exp\left[ i \left( p_{y_s} + p_{z_s} z_s \right)/\hbar \right],
\]

and, finally, \( \psi_{\text{ref}} \) the reflected wave,

\[
\psi_{\text{ref}}(y_s, z_s) = \exp\left[ i \left( p_{y_s} - p_{z_s} z_s \right)/\hbar \right].
\]

Region I \( (z_s < d_s) \) represents the plane zone which is potential free. Consequently, from the Schrödinger equation, we obtain the well-known momentum/energy relation,

\[
p_{y_s}^2 + p_{z_s}^2 = p^2 = 2mE.
\]
In region II \((z_* > d_*)\), the solution is given by
\[
\psi_{II}(y_*, z_*) = t \exp\left[ i \left( p_{y_*} y_* + q_{z_*} z_* \right)/\hbar \right],
\]  
(7)
where \(t\) is the transmission amplitude and, due to the fact that the discontinuity is along \(z_*\), the momentum component perpendicular to this axis is not influenced by the potential, consequently \(q_{y_*} = p_{y_*}\). From the Schrödinger equation in the presence of step-wise potentials \((z_* > d_*)\),
\[
E \psi_{II}(y_*, z_*) = -\left[ \frac{\hbar^2}{2m} \left( \partial_{y_*} y_* + \partial_{z_*} z_* \right) - V_1 \right] \psi_{II}(y_*, z_*) ,
\]  
(8)
we obtain the following momentum/energy relation:
\[
p_{y_*}^2 + q_{z_*}^2 = 2m \left( E - V_1 \right) p^2 = n^2 p^2 ,
\]  
(9)
where we have introduced the dimensionless quantity
\[
n = \sqrt{1 - \frac{V_1}{E}}.
\]  
(10)
The incoming wave has a momentum \(p\) and moves along \(z\). The incidence angle with respect to the \(z_*\)-axis is \(\theta\),
\[
p_{z_*} = p \cos \theta .
\]  
The transmitted wave moves in the potential region with momentum \(np\). The transmitted angle is \(\phi\) (see Fig. 1(a)), consequently
\[
q_{z_*} = np \cos \phi .
\]  
From Eq. (9), we find
\[
p^2 \sin^2 \theta + n^2 p^2 \cos^2 \phi = n^2 p^2
\]  
which implies
\[
\sin \theta = n \sin \phi .
\]  
(11)
Thus, we recover the Snell law given in the beginning of this section. As it is illustrated in Fig. 1(a), an incoming particle with energy \(E = 3 V_1\) which moves along the \(z\)-axis forming an angle \(\pi/4\) with respect to the \(z_*\)-axis, will be deflected, in the potential region, forming an angle \(\phi\) with respect to the \(z_*\)-axis. Before concluding this section, we observe that from the continuity equations for the wave function and its derivative at the discontinuity \(z_* = d_*\), we find the following reflection amplitude:
\[
r = \frac{\cos \theta - \sqrt{n^2 - \sin^2 \theta}}{\cos \theta + \sqrt{n^2 - \sin^2 \theta}} \exp\left[ 2i p_{z_*} d_* \right] = \frac{1 - n^2}{\left( \cos \theta + \sqrt{n^2 - \sin^2 \theta} \right)^2} \exp\left[ 2i p_{z_*} d_* \right].
\]  
(12)
From the reflection amplitude is immediately seen that for \(\sin \theta > n\),
\[
r = \frac{1 - n^2}{\left( \cos \theta + i \sqrt{\sin^2 \theta - n^2} \right)^2} \exp\left[ 2i p_{z_*} d_* \right]
\]  
\[
= \exp\left[ 2i \left( p_{z_*} d_* - \arctan \left[ \frac{\sqrt{\sin^2 \theta - n^2}}{\cos \theta} \right] \right) \right],
\]  
(13)
we have total internal reflection. In Fig. 1(a), where \( E = 3 V_1 \), the critical angle is given by

\[
\theta_c = \arcsin \left( \frac{\sqrt{2}}{3} \right) \approx \frac{\pi}{3.29} .
\]  

III. QUATERNIONIC QUANTUM MECHANICS AND SNELL LAW

In Sec. II, we have obtained the Snell law and the reflection coefficient for planar motion in the presence of complex potentials. Is the Snell law somehow modified if we repeat the previous analysis for Schrödinger equation in the presence of a quaternionic potential? The answer is yes and we are going to show how.

The time-independent Schrödinger equation in the presence of a quaternionic potential,

\[
\hbar \cdot V(z^*) = \begin{cases} 0 & \text{for } z^* < d^* \quad \text{and} \quad i V_1 + j V_2 + k V_3 & \text{for } z^* > d^* \end{cases},
\]

is given by\(^7\),\(^17\)

\[
-i E \Psi_{II}(y^*, z^*) i = - \left[ \frac{\hbar^2}{2m} \left( \partial_{y^*y^*} + \partial_{z^*z^*} \right) + \hbar \cdot V \right] \Psi_{II}(y^*, z^*) = H \Psi_{II}(y^*, z^*). \tag{15}
\]

Multiplying the previous equation from the left by the quaternionic conjugate operator of \( H \) (\( \bar{H} \)) and observing that \( \bar{H} i = i H \), we get

\[
E^2 \Psi_{II}(y^*, z^*) = \bar{H} H \Psi_{II}(y^*, z^*) = \left[ \frac{\hbar^4}{4m^2} \left( \partial_{y^*y^*} + \partial_{z^*z^*} \right)^2 - \frac{\hbar^2}{m} V_1 \left( \partial_{y^*y^*} + \partial_{z^*z^*} \right) + |V|^2 \right] \Psi_{II}(y^*, z^*). \]

From the previous equation, we obtain the solution which generalizes the complex solution \( q_{z^*} \), i.e.,

\[
p_{y^*}^2 + Q_{z^*}^2 = 2m \left( \sqrt{E^2 - V_2^2 - V_3^2} - V_1 \right), \tag{16}
\]

which characterizes the plane wave in the potential region,

\[
\exp \left[ i \left( p_{y^*}, y^* + Q_{z^*}, z^* \right) / \hbar \right],
\]

and the additional solution

\[
p_{y^*}^2 + Q_{z^*}^2 = -2m \left( \sqrt{E^2 - V_2^2 - V_3^2} + V_1 \right) \tag{17}
\]

which generates evanescent wave solutions in \( z^* \). We shall give the explicit quaternionic solutions in Sec. IV. Let us now examine how the Snell law is modified by the new momentum \( Q_{z^*} \). From Eq. (16), we find

\[
p_{y^*}^2 + Q_{z^*}^2 = \left( \sqrt{1 - \frac{V_2^2 + V_3^2}{E^2} - V_1} \right) 2m E = N^2 p^2 . \tag{18}
\]

The presence of a quaternionic part in our potential generates the refractive index

\[
N = \sqrt{1 - \frac{V_2^2 + V_3^2}{E^2} - \frac{V_1}{E}} \tag{19}
\]

and consequently the new Snell law

\[
\sin \theta = N \sin \phi . \tag{20}
\]
As it is illustrated in Fig. 1(b), if we replace the complex potential $V_1$ by a pure quaternionic potential of the same modulus $\sqrt{V_2^2 + V_3^2} = E/3$ the transmitted beam will experience a different deflection

$$\Phi = \text{arcsin} \left[ \frac{1}{N} \sin \theta \right] = \text{arcsin} \left[ \sqrt{\frac{3}{2\sqrt{2}}} \frac{1}{\sqrt{2}} \right] \approx \frac{\pi}{3.85}.$$ 

The critical angle is now defined in terms of the complex ($V_1$) and quaternionic ($V_2, V_3$) parts of the potential

$$\theta_C \left[ \frac{V_1}{E}, \sqrt{\frac{V_2^2 + V_3^2}{E}} \right] = \text{arcsin} \left[ \sqrt{1 - \frac{V_2^2 + V_3^2}{E^2} - \frac{V_1}{E}} \right], \quad (21)$$

which for the case illustrated in Fig. 1(b) where $V_1 = 0$ and $E = 3 \sqrt{V_2^2 + V_3^2}$ gives

$$\theta_C = \text{arcsin} \left[ \frac{2\sqrt{2}}{3} \right] \approx \frac{\pi}{2.36}. \quad (22)$$

In Fig. 2, we show the potential dependence for the critical angle. In particular in Fig. 2(a), we compare the critical angle behavior for complex and pure quaternionic potential of the same modulus. The plot clearly shows that pure quaternionic potentials have a greater diffusion zone than complex

![Diagram showing potential dependence of the critical angle](image-url)

**FIG. 2.** Potential dependence of the critical angle $\theta_C[ V_1/E, \sqrt{V_2^2 + V_3^2}/E ]$. In (a), we compare complex with pure quaternionic potentials of the same modulus. In (b), we illustrate how the introduction of quaternionic perturbations on complex potentials modifies the critical angle.
potentials. This can be explained by noting that
\[
\sin^4 \theta_C [0, x] - \sin^4 \theta_C [x, 0] = x (2 - x).
\]

We conclude this section, by observing that for small quaternionic perturbations on complex potential, the new refractive index \( N \) can be rewritten in terms of the standard refractive index \( n \) as follows:
\[
N \approx n - \frac{V_r^2 + V_i^2}{4n E^2}.
\]

The effect of quaternionic perturbations on complex potentials is illustrated in Fig. 2(b).

IV. THE REFLECTION AMPLITUDE FOR QUATERNIONIC POTENTIALS

To find the reflection amplitude in quaternionic quantum mechanics, we have to impose the continuity of the wave function and its derivative at the potential discontinuity \( d_s \). In the free potential region, \( z_s < d_s \), the quaternionic solution is given by\(^7\)
\[
\Psi_j(y_s, z_s) = \{ \exp[i p_z, z_s] + R \exp[-i p_z, z_s] + j \tilde{R} \exp[p_z, z_s] \} \exp[i p_y, y_s].
\]

In the potential region, \( z_s > d_s \), the solution of Eq. (15), obtained after some algebraic manipulations, reads\(^12\)–\(^14\)
\[
\Psi_{II}(y_s, z_s) = \{ (1 + j \beta) T \exp[i Q_z, z_s] + (\alpha + j) \tilde{T} \exp[i \tilde{Q}_z, z_s] \} \exp[i p_y, y_s],
\]
where
\[
\alpha = i \frac{V_2 + i V_3}{E + \sqrt{E^2 - V_2^2 - V_3^2}}, \quad \beta = -i \frac{V_2 - i V_3}{E + \sqrt{E^2 - V_2^2 - V_3^2}},
\]
and
\[
Q_z = \sqrt{N^2 - \sin^2 \theta} \, p, \quad \tilde{Q}_z = i \sqrt{1 - \frac{V_2^2 + V_3^2}{E^2} + \frac{V_1}{E} + \sin^2 \theta} \, p.
\]

From the continuity equations, we get
\[
\tilde{R} \exp[p_z, d_s] = \beta T \exp[i Q_z, d_s] + \tilde{T} \exp[i \tilde{Q}_z, d_s],
\]
\[
p_z, \tilde{R} \exp[p_z, d_s] = i \{ \beta T Q_z \exp[i Q_z, d_s] + \tilde{T} \tilde{Q}_z \exp[i \tilde{Q}_z, d_s] \},
\]
which implies
\[
\tilde{T} \exp[i \tilde{Q}_z, d_s] = \frac{p_z - i Q_z}{i \tilde{Q}_z - p_z} \, \beta T \exp[i Q_z, d_s],
\]
and
\[
\exp[i p_z, d_s] + R \exp[-i p_z, d_s] = T \exp[i Q_z, d_s] + \alpha \tilde{T} \exp[i \tilde{Q}_z, d_s]
\]
\[
= \left( 1 + a \beta \frac{p_z - i Q_z}{i \tilde{Q}_z - p_z} \right) T \exp[i Q_z, d_s],
\]
\[
\exp[i p_z, d_s] - R \exp[-i p_z, d_s] = \frac{Q_z}{p_z} T \exp[i Q_z, d_s] + \tilde{Q}_z \frac{\tilde{Q}_z}{p_z} \alpha \tilde{T} \exp[i \tilde{Q}_z, d_s]
\]
\[
= \left( \frac{Q_z}{p_z} + a \beta \frac{\tilde{Q}_z}{p_z} \frac{p_z - i Q_z}{i \tilde{Q}_z - p_z} \right) T \exp[i Q_z, d_s],
\]
from which we obtain
\[
R \left[ \frac{V_1}{E}, \frac{\sqrt{V_2^2 + V_3^2}}{E} \right] \theta = \frac{A_-}{A_+} \exp[2 i p_z, d_s],
\]
(27)
REFLECTION AMPLITUDE BEHAVIOR

where

\[ A_\pm = (p_z, \pm Q_z)(i \tilde{Q}_z - p_z) + \alpha \beta (p_z, -iQ_z)(p_z, \pm \tilde{Q}_z). \]

Taking the complex limit of Eq. (27), observing that \( \alpha \beta \to 0 \) and \( Q_z \to q_z \), we obtain

\[
R \left[ \frac{V_1}{E}, 0; \theta \right] = \frac{p_z - q_z}{p_z + q_z} \exp[2i\exp(d_z)]
= \frac{V_1}{E} \exp[2i\exp(d_z)] / \left( \cos \theta + \sqrt{\cos^2 \theta - \frac{V_1}{E}} \right)^2
\]

and recover the result given in Sec. II, see Eq. (12). Observe that for \( E \cos \theta < V_1 \) we have total internal reflection. In Fig. 3, we plot the reflection amplitude behavior for fixed incidence angles as a function of the potential (see Fig. 3(a)) and for a fixed potential as a function of the incidence angle (see Fig. 3(b)). From the plots it is evident that by increasing the quaternionic part of the potential we increase the diffusion zone.

V. CONCLUSIONS

The well-known analogy between optics and complex quantum mechanics\(^5,6\) allows to obtain the relationship between the sine of the angles of incidence, \( \theta \), and refraction, \( \varphi \), of waves passing through a boundary between two different isotropic media, i.e.,

\[ \sin \theta = n \sin \psi, \]

FIG. 3. Reflection amplitude behavior for a fixed incidence angle as function of the potential (a) and for a fixed potential as function of the incidence angle (b). The plots clearly show that, by increasing the quaternionic part of the potential, we increase the diffusion zone. Consequently, the reflection probability decreases with respect to complex potentials.
by analyzing the planar motion of a quantum particle moving from the free region, \( z_* < d_* \), to the potential region \( V_1, z_* > d_* \). In the complex case, the refractive index is given by

\[
n = \sqrt{1 - \frac{V_1}{E}},
\]

where \( E \) is the energy of the incoming particle. In this paper, we have extended such a study to quaternionic potentials. The presence of a quaternionic part in the potential modified the refractive index as follows:

\[
N = \sqrt{1 - \frac{V_2^2 + V_3^2}{E^2} - \frac{V_1}{E}}.
\]

Consequently, the new Snell law becomes

\[\sin \theta = N \sin \phi.\]

The potential dependence of the critical angle, see Fig. 2, and the reflection amplitude behavior as a function of the complex/quaternionic potential ratio, see Fig. 3(a), and of the incidence angle, see Fig. 3(b), allow to know in which situations we can distinguish between complex and quaternionic potentials.

Finally, in the tunneling energy zone, \( \sqrt{V_2^2 + V_3^2} < E \) and \( |V| > E \), we find \( Q_* = i |Q_*|, \) \( \tilde{Q}_* = i |\tilde{Q}_*|, \) and \( \alpha \beta \in \mathbb{R} \). In this limit,

\[
A_\pm \rightarrow -(p_x \pm i |Q_*|)(p_x + |\tilde{Q}_*|) + \alpha \beta (p_x + |Q_*|)(p_x \pm i |\tilde{Q}_*|) \Rightarrow |R| = 1.
\]

For total reflection, the addition phase in the reflection coefficient is responsible for the Goos-Hänchen shift. In a forthcoming paper, we shall investigate in detail the phase change which takes place on total reflection. This study could be useful to identify in which dielectric systems quaternionic deviations from the complex optical path can be seen. Another interesting generalization of the analysis presented in this paper is represented by the possibility to extend the non-relativistic quaternionic discussion to the quaternionic relativistic case and eventually to Clifford algebras.
