INTRODUCTION: COVID-19 vaccine hesitancy is a worldwide phenomenon and a serious threat to pandemic control efforts. Until recently, COVID-19 vaccine hesitancy was not the cause of low vaccine coverage in Nigeria; vaccine scarcity was the problem. As the global supply of COVID-19 vaccines improves in the second half of 2021 and more doses are deployed in Nigeria, the supply/demand dynamic will switch. Vaccine acceptance will become a key driver of coverage; thus, amplifying the impact of vaccine hesitancy. Conspiracy theories and misinformation about COVID-19 are rampant and have been shown to drive vaccine hesitancy and refusal. This study systematically elicits the misinformation and conspiracy theories circulating about COVID-19 among the Nigerian public to understand relevant themes and potential message framing for communication efforts to improve vaccine uptake.

METHODS: From February 1 to 8, 2021, we conducted 22 focus group discussions and 24 key informant interviews with 178 participants from six states representing the six geopolitical zones. Participants were purposively selected and included sub-national program managers, healthcare workers, and community members. All interviews were iteratively analyzed using a framework analysis approach.

RESULTS: We elicited a total of 33 different conspiracy theories or misinformation that participants had heard about the COVID-19 virus, pandemic response, or vaccine. All participants had heard some misinformation. The leading claim was that COVID-19 was not real, and politicians took advantage of the situation and misused funds. People believed certain claims based on distrust of government, their understanding of Christian scripture, or their lack of personal experience with COVID-19.

CONCLUSIONS: Our study is the first to report a thematic analysis of the range of circulating misinformation about COVID-19 in Nigeria. Our findings provide new insights into why people believe these theories, which could help the immunization program improve demand generation communication for COVID-19 vaccines by targeting unsubstantiated claims.

Health Organization (WHO) describes the overwhelming volume and circulation of false information about the SARS-CoV-2 pandemic as an “infodemic” that seriously threatens global and local efforts to end the pandemic.

Nigeria was among the first countries in sub-Saharan Africa to identify COVID-19 cases [5]. Since the Federal Ministry of Health reported its first index case on February 27, 2020 [6], Nigeria has deployed public health and social measures such as banning public gatherings and restricting movement and businesses to curb the virus transmission. As of December 23, 2021, Nigeria has 231,413 cases across all states, of which 211,853 were discharged and 2991 confirmed dead [7]. Since the pandemic, males are mostly affected than females, with a 60: 40 case ratio and 74:26 death ratio [7]. Individuals 50 years and above account for 70% of the mortality burden [7]. All states in the country are affected, but most cases are reported in Lagos and the Federal Capital Territory (FCT) [7]. While recent data trends have suggested a continuous decrease in the number of cases, the spread of the pandemic, the second wave in December 2020 [8], and non-adherence to non-pharmaceutical preventive measures underscored the need for an effective vaccine. Vaccination with safe and effective COVID-19 vaccines is critical for Nigeria’s strategy to interrupt the COVID-19 pandemic and curb transmission.

Historically, Nigeria has grappled with highly disruptive vaccine hesitancy and refusal resulting from negative rumors and loss of public confidence. For example, in 2003, a rumor that the oral polio vaccine contained porcine material and sterilizing agents led to a boycott of polio vaccination in Northern Nigeria. Following this vaccine boycott, an upsurge in polio cases resulted in wild-polio re-infection in 20 countries across Africa and Asia [9–11] and retrogression of polio eradication efforts in Nigeria and the African region. In 2017, another rumor broke out in the country’s Southeastern part, purporting that the Nigerian military was “vaccinating” school children with the monkeypox virus [12]. This false story led panicked parents to withdraw their children from school and, uncharacteristically, refuse to take them for vaccination. Soon after that, vaccination rates dropped in that part of the country – a region that previously had some of the highest vaccine uptake rates in the country.

Early vaccine procurement, domestic production of vaccines, the severity of the pandemic, a country’s health infrastructure, and vaccine acceptance are significant determinants of COVID-19 vaccine coverage [13]. However, evidence has shown that widespread vaccine acceptance is crucial for achieving sufficient immunization coverage [14]. Until recently, hesitancy surrounding COVID-19 vaccines was not the top programmatic bottleneck to widespread use of COVID-19 vaccines in Nigeria and other low- and middle-income countries (LMICs) because the vaccines were in short supply globally. Thus, like other LMICs, Nigeria introduced COVID-19 vaccines with barely enough doses to cover 1% of the population, with vaccine demand far outstripping vaccine supply. As the global supply of COVID-19 vaccines improves in the second half of 2021 and more doses become available and deployed in LMICs, demand and acceptance, along with absorption capacity, will become the top coverage drivers. Therefore, the need to address vaccine hesitancy will become even more critical and urgent. For example, Nigeria received 40 million COVID-19 vaccine doses in August 2021 and commenced the second vaccination phase [15]. With the planned deployment of millions of vaccine doses, demand generation activities must take center stage, and part of this effort must include practical strategies to address and debunk misinformation and conspiracy theories about COVID-19 and COVID-19 vaccines. We use the term misinformation to denote false or inaccurate information or communication [16]. We consider conspiracy theories as a particular kind of false information in which the creators of conspiracy theories attribute the root causes of events or trends to shadowy networks or cabals carrying out secret plots to control, undermine or exploit the public, governments, or institutions [17]. Conspiracy theories reject the standard explanations for significant phenomena and instead credit covert actors and manipulators.

For a vaccination program to succeed, implementers must first understand and contextualize the range, breadth, and depth of circulating misinformation and conspiracy theories. It is also important to understand the patterns and drivers of belief in these conspiracy theories and how these beliefs affect vaccination intentions in the communities and among different demographic groups. This study was designed to systematically elicit the circulating COVID-19 misinformation and conspiracy theories that the Nigerian public had heard or read. We also sought to describe the themes and patterns of beliefs associated with these narratives to produce evidence to guide communication efforts towards reducing vaccine hesitancy and improving uptake. At the time of data collection, COVID-19 vaccines had not yet been deployed in the country, although the plans for introduction were advanced.

2. Methods

2.1. Study setting

We conducted the study in six of the 36 states in Nigeria: Cross Rivers, Ebonyi, Gombe, Kano, and Lagos states, including the FCT. These states were selected to represent each of the six geopolitical zones in the country and reflect states with a low, medium, and high burden of COVID cases relative to the national picture. See Supplementary Materials 1 and 2 for details. Following this, we selected two local government areas (LGAs) /sub-districts in each state/district to ensure a mix of settings that represent demographic, logistical, and epidemiologic diversity, as follows: 1) rural, urban, and semi-urban, 2) proximal and distal to the state capital, 3) SARS-CoV-2 transmission hot and cold spots, and 4) presence of a research partner organization to support data collection. A total of 12 LGAs were selected and visited.

2.2. Study design

This paper only presents the qualitative arm of a mixed-methods study that used qualitative and quantitative approaches to examine the phenomenon of misinformation and conspiracy theories about COVID-19 and COVID-19 vaccines in Nigeria. We conducted focus group discussions (FGDs) and key informant interviews (KIIs) to examine the misinformation and conspiracy theories surrounding the SARS-CoV-2 pandemic.

2.3. Study participants and sampling

We purposively selected participants for both the FGDs and KIIs from routine immunization (RI) program personnel and community members. The RI program personnel were program managers at the state and LGA levels and healthcare workers (HCWs) at primary health care (PHC), secondary, or tertiary care levels. Program managers and HCWs were aged 18 years and above and occupied their current roles for at least a year. Community members included pregnant women, parents of children under five years of age, and Christian and Muslim religious leaders. We also selected male and female youths (18 – 24 years), adults (25 – 49 years), and older adults (≥50 years). To be eligible for the FGDs, community participants had to be 18 years or older and residents in the community for at least one year to ensure familiarity with community norms. For the FGDs and KIIs, we excluded individuals screened and assessed to have COVID-19 symptoms. Community
leaders identified FGD participants with the help of local HCWs or
immunization program managers in the state. The State Primary
Health Care Board and the State Emergency Routine Immunization
Coordinating Centre identified the KII participants, most of whom
were immunization program managers. All the persons nominated
for the interviews agreed to participate in the study.

In total, we conducted 22 FGDs and 24 KIs among 178 people
from February 1 to 8, 2021. All 24 KIs were conducted with state
and LGA program managers and HCWs. Sixteen FGDs were con-
ducted with community members, three with religious leaders,
and three with HCWs. At least three KIs and three FGDs were con-
ducted in each of the six states. Supplementary Materials 3 pro-
vides a complete list of the participants, interviews conducted,
and the number of participants interviewed.

2.4. Data collection

Our trained data collectors conducted the FGDs and KIs using
pre-tested semi-structured interviews and discussion guides and
the tracking sheet to collect participants’ socio-demographic infor-
mation. After obtaining verbal consent, all interviews (FGDs and
KIs) lasted between 45 and 60 min. While the KIs were conducted
at the participant’s home or a convenient location, the FGDs were
conducted outdoors. Interview guides were in English. However,
data collectors conducted interviews in local languages to ease
communication and understanding. Interviews conducted in local
languages were transcribed in the language by external vendors
and back-translated to English for validation. We provided FGD
participants at the community level one thousand naira only
($2.6) for logistics during the study data collection period.

Data collection teams followed all COVID-19 preventive guide-
lines such as masking, hand washing with soap and water, and
maintaining 2 m distance between each other before and during
the interviews. The researchers provided the teams’ supervisors
with portable infrared thermometers for daily temperature screen-
ing of data collectors during the fieldwork. At the start of each
day’s activities, the team supervisor verbally screen ed data collec-
tion teams for COVID-19 symptoms. Likewise, data collectors con-
ducted verbal symptom screening and temperature checks on
participants before interviews to rule out suspected COVID-19
cases. There were no suspected COVID-19 cases amongst the field
staff and the participants during the data collection period.

2.5. Data analysis

We analyzed the qualitative interviews iteratively using a
Framework Analysis approach, adapted from the WHO behavioral
and psychosocial determinants of vaccine acceptance framework
[18] and Gale et al. framework methodology [19]. First, we
audio-recorded all interviews and transcribed them verbatim.
Three study team members read the transcripts for content compre-
ension and familiarization. Then, ten transcripts were ran-
domly selected and coded independently by three team
members. The team members then compared the codes across
the three coders to generate the first unified set of codes. Third,
the study team used these unified codes to create the initial analyt-
cal framework. Upon reading subsequent transcripts, the initial
analytical framework was revised iteratively until we generated
no new codes. Recurrent codes, similar or related codes, were
grouped into defined categories, culminating into our final frame-
work, consisting of 68 unique codes clustered into 31 categories.
These codes and categories were used to abstract data from each transcript.

The study team generated themes by reviewing and collating
categories and their associated patterns. We further reviewed each
theme to ensure an accurate representation of the data and
included a brief explanatory description of its meaning. Subse-
quently, connections across participants, categories, and themes
were drawn by reviewing the summary spreadsheet of abstracted
data. We also analyzed the themes and categories for geographic
patterns. We anonymized the quotes for confidentiality. It is worth
noting that this process was influenced both by the research objec-
tives and by new concepts generated inductively from the data.
Supplementary Material 4 presents the analytical framework used
in this study. The completed interview tracking sheets were
entered into Microsoft Excel and analyzed descriptively for fre-
quencies and percentages.

2.6. Ethics approval

We obtained ethics approval for the study from the National
Health Research Ethics Committee of Nigeria (NHREC/01/01/2007-05/11/2020) and the Johns Hopkins Univer-
sity Institutional Review Board (IRB00014705). We also obtained
additional state-level ethics approval from the Health Research
Ethics Committees in Cross River, Ebonyi, Gombe states, and the
FCT as was required. These research ethics committees reviewed
and approved the oral consent script used to solicit consent from
all individuals interviewed.

3. Results

3.1. Socio-demographic characteristics of study participants

We conducted 46 individual interviews and group discussions with 178 participants, the majority of whom were community
members 134 (75%), females 97 (54%), urban residents 122 (69%),
and individuals with formal education 146 (82%). Participants’ ages
ranged from 20 to 80 years, with a mean age of 40 ± 12.8 years
(Table 1).

3.2. Prevalent conspiracy theories and misinformation about COVID-
19 and the vaccines

Rather than give participants a list of conspiracy theories or
misinformation to choose from, we elicited their responses by ask-
ing what they had heard in their community or read about COVID-
19 and the vaccines. We elicited a total of 33 different statements. It is noteworthy that each respondent had heard at least one con-
sspiracy theory or piece of misinformation about the subject. Analy-
thesis of the statements they volunteered revealed three broad
themes of the misinformation and conspiracy theories– statements
about the nature of the virus, the motivations and validity of the
pandemic response, and the vaccine products (Fig. 1).

More than half of the participants had heard misinformation or
conspiracy theories about the virus itself. Some reported hearing
the virus was manufactured in laboratories, was a biological
weapon or resulted from 5G technology.

One respondent heard, “COVID is not a natural disease; it was
technologically developed” – State program officer (KII).

The statements claiming the virus was man-made did not indi-
cate who made them. In sharp contrast, other circulating narratives
associated the viral origin with God and the Anti-Christ. For exam-
ple, some participants said they had heard that the COVID-19 pan-
demic is a sign of the end times, a fulfillment of the scriptures, a
result of God’s anger, a punishment for politicians from God, a plan
of the devil, and a plot of the Anti-Christ. These apocalyptic inter-
pretations based on the Christian text were reported by seven par-
ticipants, a Christian religious leader, two male adults, and four
health workers.
“Religiously, some will tell you it is the fulfilment of the scripture, where, in the book of Deuteronomy chapter 28 God says any person or any group of persons, I am paraphrasing anyway, who lives in disobedience, God will send down incurable diseases among them; so, those who believe in such warnings will say; ah! this is the fulfilment of the scripture.” – Health worker (KII)

Another subset of statements about the virus neither referred to nefarious networks creating the virus nor to God sending it but were alternative disease models of the COVID-19 experience in Nigeria. Nearly half of the participants heard statements that COVID-19 cannot survive the hot Nigerian weather, there was no COVID-19 in the country (though it exists elsewhere), or that COVID-19 was a disease of city dwellers or rich people. Some heard COVID-19 is just another form of malaria and that chloroquine was the treatment for it.

A second narrative thread revolved around the pandemic response. These included statements that the pandemic response is a fraud, that the government exaggerates the COVID-19 situation in the country, and that politicians are using COVID-19 as an excuse to siphon money from the Nigerian government. Related to this concept of a fraudulent response effort was the most frequently reported statement in all categories- that COVID-19 is not real, with beliefs that there were ulterior motives behind case reports.

“It [COVID] is not in Nigeria; the government is just using it to swindle public funds. It is just malaria.” – Male adult (KII)

Regarding the third theme of COVID-19 vaccines, a subset of such statements claimed the vaccine was a tool for foreign dominance and profiteering. Many participants heard that the COVID-19 vaccines would be used to control or reduce the African population and would be a means to implant microchips in people to track them. There were also statements about the vaccines serving as a mode of introducing the 666 mark of the Anti-Christ.

“I am a Christian pastor, I am a Christian, and I also have followers under me... some of us think that this COVID 19 vaccine is a way of introducing 666 controls on the world”- Christian religious leader (KII)

The other subset of statements on the vaccines characterized them as lacking safety, efficacy, and quality, particularly those deployed in Nigeria. Participants reported hearing that the vaccines change people’s DNA, alter the body’s metabolism, and cause harmful reactions. They also heard that the vaccines used in Nigeria are different from those used in wealthier countries.

### Table 1

| Characteristics                              | Number (n = 178) | Percentage (%) |
|----------------------------------------------|------------------|----------------|
| **Participant type**                         |                  |                |
| Community members                           | 134              | 75%            |
| Program managers                             | 32               | 18%            |
| Health workers                               | 12               | 7%             |
| **Sex**                                      |                  |                |
| Male                                         | 81               | 46%            |
| Female                                       | 97               | 54%            |
| **Residence**                                |                  |                |
| Urban                                        | 122              | 69%            |
| Rural                                        | 56               | 31%            |
| **Attended formal education**                |                  |                |
| Yes                                          | 146              | 82%            |
| No                                           | 32               | 18%            |
| **Highest level of formal education completed** |                |                |
| None                                         | 32               | 18%            |
| Primary School                               | 15               | 8%             |
| Secondary School                             | 55               | 31%            |
| Graduate                                     | 62               | 35%            |
| Post-Graduate                                | 14               | 8%             |

### Fig. 1

Conspiracy theories and misinformation about COVID-19 and the vaccines in Nigeria.
National Primary Health Care Development Agency (NPHCDA) as reliable because it is evidence-based, and these agencies were responsible for handling the crisis. Most community members regarded information received from the radio and television as trustworthy, while a few thought the same about information from the WHO and NCDC. Most participants believed social media information is unreliable because it is subjective and open for anybody to publish.

“We know that we are in the days of social media and fake news everywhere. Some information cannot be faulted, like some from international bodies like the World Health Organization. This information is research information and is from the horses’ mouth.” – Religious leader (FGD)

### 3.4. Belief in conspiracy theories

We explored why people might believe in these theories and found that reasons vary by the type of misinformation or conspiracy theory people subscribe to. For example, participants reported that some people did not believe in the existence of COVID-19 because they had not had a personal experience with a COVID-19 case or death.

“They don’t believe because, in a community, no one has contracted it.” – Religious leaders (FGD)

“Because they have not seen any impact of the COVID. We are in this community, … we are more than one thousand people, and one day, they have never seen even one person affected by COVID.”

– Male Adult (KII)

Furthermore, those considering Nigeria’s tropical climate too hot for the virus to survive tended to believe there was no COVID-19 in Nigeria. The belief that the pandemic response was a fraud, and a means for official graft, was rooted in the concurrent denial of the existence of the virus and distrust of the government’s integrity and intentions.

“Actually, the society at large, the people, do not trust the government. The system is surely corrupt. Though I believe it [COVID] exists, I have not seen anybody that has died because of it… Abroad, there is transparency, but here, they [government] just do it to get financial assistance from monetary bodies. At the same time, if you look at the society, I have not heard a single person having the COVID.” – Religious leader (FGD)

In contrast, we found that those who reject the notion that COVID-19 is not in Nigeria or accept that COVID-19 is real have had personal experience with COVID-19 or seen or heard about someone affected or died due to the disease. When asked about their perception of COVID-19, most participants said they believe COVID-19 is real, and few said they do not.

“I do [believe COVID is real]. Because we have lost so many people due to COVID, many people have been isolated and become unhealthy; that’s why I believe in it.” – Pregnant woman (KII)

Furthermore, participants’ belief in the reality of COVID-19 was linked to perceived susceptibility to contracting COVID-19, the global impact of the virus, and the scale of the response, including national lockdowns.

“Initially, people were trying to convince us that this thing is not real, that the government is just using it to siphon money. At a time, I started to believe, but I discovered that the whole world was still. I believe because if it is not real, the whole world will not stand still”. – Male Adult (FGD)

Participants offered various characteristics when asked about the typical believers and supporters of conspiracy theories and the misinformation about COVID-19. These included: being uneducated or religious, being young with access to information, being elderly with no access to traditional and social media, and having not known or seen someone affected or killed by COVID-19. Some cited those in the Southeast who distrust the present political leadership and those in the North who reject Western interventions.

“The belief of Igbo is different. The Igbo people do not believe whatever [the President] says”. – Religious leader (FGD)

“Basically, those that do not trust anything Western are the hardcore Muslims, not the regular Muslims but hardcore Muslims. Then those that do not believe the government tends to be the Igbo speaking part of our country”. – Program manager (KII)

We inquired into how belief or sympathy for conspiracy theories may affect the intention to accept a COVID-19 vaccine. While some said it would not affect their intent to take the vaccine, others believed it would, given the circulating misinformation.

“…I have a lot of things I am considering. I still have conflicting information about COVID-19 vaccines so, I am still watching to see what will happen. I believe in vaccines, but there is more information that we stumble on these days, and they make you go thinking”. – Religious leader (FGD)

“This is where the issue is. With the current spread of the news, or let me say rumor, it has made me believe that the vaccine is harmful, and they want to use it to reduce the population of Africa. Presently, I am privileged to be part of some Christian gathering that think there is a plan, and the vaccine they are planning to bring down here is not the same as that of the one over there. That is why they want the leaders to take it first and observe if anything does not happen; we will now know what to do”. – Male adult (KII)

### 3.5. Perceptions about COVID-19 vaccines versus other vaccines (and immunization more broadly)

To examine the extent to which hesitancy around COVID-19 vaccines was distinct from or part of broader vaccine hesitance, we looked comparatively at statements about other vaccines and the immunization schedule favorably due to the positive track record of eradication.
ing diseases and preventing morbidity and deaths, especially among children.

“Our children suffer much before because there is no vaccination… we now find it easier to take care of our children due to vaccination”. – Pregnant women (FGD)

In contrast, participants’ opinions about the COVID-19 vaccines varied. Nearly half of the participants had concerns about the COVID-19 vaccines. For example, community members were concerned about vaccine efficacy and safety due to reported side effects and unease about the short period of vaccine development. Other concerns raised were that the vaccines are not needed in Nigeria because COVID-19 is not real, and they had not seen an infected person. It was also perceived that the African continent has a low death rate from COVID-19.

“The rumor is why are they centered on bringing the vaccine here when there is a low death rate in Africa compared to other Western countries like America, where their death rate is very high. Let them use it to cure themselves because we have a low death rate here. Also, the rate at which they produced the vaccine within a short period of time when they said it should take at least three years to produce a vaccine. Is the vaccine to cure, prevent or even kill, we don’t know?”. – Male adult (FGD)

Likewise, the lack of information on the duration of the vaccine’s protection, perception that the government is not transparent about the vaccines, and poor communications about the threat of COVID-19 to the public were mentioned as concerns. Furthermore, participants also felt that not knowing the timing of the vaccine availability and where to access the vaccine was problematic.

Some health workers and program managers also shared the same view, including concerns about vaccine storage capacity due to insufficient power.

“Well, we are still having a little doubt because they are saying it is 50–50, that is 50% effective and 50% not effective”. 

“Yes, I have an opinion because it is like they need to enlighten us because so many theories are coming out concerning the vaccine, of which now if they bring the vaccine, I doubt if I can take it. Because honestly, I need to know the effectiveness of the vaccine, how safe it is; you know there are so many stories concerning it”. – Health workers (FGD)

Nevertheless, about half of the participants had favorable feelings towards the COVID-19 vaccines. Many of them were program managers and health workers who perceived the vaccines as safe and effective in protecting against COVID-19 and trusting the government to introduce safe and effective vaccines.

4. Discussion

Our study aims to collate and categorize the circulating conspiracy theories and misinformation around COVID-19 and COVID-19 vaccines in Nigeria to inform evidence-based communication messaging and intervention strategies. To our knowledge, this is the first thematic analysis of circulating conspiracy theories and misinformation about COVID-19 elicited through a qualitative inquiry from HCWs and adults in Nigeria. We found that exposure to unsubstantiated claims about COVID-19 was universal among our participants, confirming the ubiquity of these false narratives. The range of statements reported in our study is similar to a list of globally circulating misinformation and conspiracy theories about COVID-19 compiled by Nyika et al. [20]. The similarity indicates the borderless and far-reaching spread of these false claims that penetrate online and offline communities and can undermine people’s confidence in the COVID-19 response and vaccination.

In our study, the leading conspiracy theory was that SARS CoV-2 does not exist; therefore, the pandemic response is a means for the Nigerian government officials and politicians to obtain pecuniary gains from misusing the response funds. This view confirms similar skepticism reported in other studies and countries about the virus being perceived as a hoax and the COVID-19 prevention efforts as an avenue for politicians to embezzle public funds [21–26]. Hoax-related conspiracy theories have been shown to predict refusal to engage in preventive behaviors, including vaccination [25]. A striking finding from this study is that the Igbo from Southeast Nigeria were perceived to have the highest level of skepticism about COVID-19. This is because of a distrust of the current government. The recent separatist movement in the Southeast has put the zone in the federal government’s crosshairs, creating a trust deficit and geopolitical tension that may now be spilling over into public health. National surveys have reported that the lowest rates of intention to receive the COVID-19 vaccine were among Southeast participants compared to those from other zones in the country [27,28]. These low rates raise fundamental concerns that high COVID-19 skepticism may translate into vaccine hesitancy among Southeasterners who have historically had one of the highest rates of childhood vaccine uptake, who also show strong faith in routine childhood vaccines in our study. Nevertheless, we posit that as more cases and deaths become evident, the claim of COVID-19 as a hoax may have less salience to those who need the evidence to convince them. However, programs must also brace for those with lingering doubts, who will continue to perceive that the pandemic is exaggerated because SARS-CoV-2 has affected Africa much less than the United States, Europe, or India.

The second striking finding is the difference in the religious interpretation of the pandemic. While our study did not report any statement linking the pandemic with Islamic text or teaching, we found that a widespread understanding of the pandemic among Christians relates it to the end-times and the Antichrist predicted in Christian scriptures. These statements have been associated with prominent Nigerian pastors with strong followship [29] and with Christian evangelicals globally [30]. Interestingly, in previous experience of polio vaccine conspiracy and hesitancy in Nigeria, misinformation about vaccines and fertility was prominent among Muslim rather than Christian groups. This underscores the importance of engaging broadly with different population subgroups, not just those with historic hesitancy, to assess concerns and craft messaging accordingly.

In countries like Nigeria, where most people have a religious identity, religious leaders can be a powerful source of misinformation. Statements linked to religious teachings are difficult to refute or debunk by public health experts because these statements are based on beliefs rooted in faith commitments that cannot be directly addressed by scientific evidence. Therefore, religious leaders are vital to addressing religious-themed claims that undermine vaccine acceptance. Studies have shown that sensitizing and engaging religious leaders increased the acceptance and uptake of novel health interventions in Nigeria [31], helped to stop the Ebola epidemic in West Africa [32], and addressed misconceptions about polio vaccines that increased vaccine coverage in India and Pakistan [33]. Religious leaders must be engaged in the fight against COVID-19.

Statements asserting COVID-19 vaccines are tools of Western actors to control or reduce the African population, track people, and alter their DNA were other commonly reported conspiracy theories in our study, as well as in other studies [34–36]. These unsubstantiated claims may hinge on long-held concerns about a structural imbalance between Africa and the Western world, as well as the colonial legacies the continent continues to bear.
Public trust in the vaccine and its foreign producers, the government, and the health system delivering the services is critical for vaccination acceptance [2,37]. Political leaders’ disparaging statements about the vaccines, such as Tanzania’s late President John Magufuli, which referred to the vaccine as “dangerous for our health” [36], are highly damaging and confusing for a skeptical public. Although some conspiracy theory beliefs are rooted in people’s distrust of the government and its institutions, these same actors have a vital role in engaging the public, building their confidence in the vaccine programs, and communicating the right messages [38,39]. It is noteworthy that information from public health agencies and experts such as WHO, NCDC, and NPHCDA were seen by our participants as trusted. In other studies, trusted information from public health agencies has been associated with a lower tendency to believe in conspiracy theories [22,38,40–42].

The medium of communicating these messages is important. We found a high level of trust in information from radio and television among community members. This finding is similar to other studies that reported that obtaining COVID-19-related information through traditional media sources is associated with lower beliefs in conspiracy theories and misinformation [22,41,43]. Conversely, exposure to digital media was associated with greater belief in conspiracy theories and misinformation [41,44,45]. A global survey reported that 88% of Nigerians cited social media as a source of their distrust. The survey also indicated that only 41% had seen fake news while using traditional media sources, and 47% sometimes believed the fake news they saw [46]. So, despite the allure and ease of using social media for information dissemination, traditional media such as radio and television must continue to play a central role in communicating credible information about COVID-19.

Our study shows that vaccine safety and efficacy concerns were a major issue and a frequent topic of misinformation. Communication messages that highlight the low risk of side effects, and high efficacy of the vaccines, will therefore address these concerns and promote vaccine acceptance. Recent evidence from ten LMICs, including Nigeria, support this assertion [47]. The study shows that respondents who were asked to consider a hypothetical vaccine with a 5% probability of side effects and 75% efficacy reported an acceptance rate of 67% or higher [47].

Finally, the current communication plans such as zonal town hall meetings, press briefings, text messages, social media posts, short videos, and voice notes aim to educate the public and encourage COVID-19 vaccine uptake as vaccines are rolled out. But, the strategy has had only a modest effect on the desired behavioral change [48]. Adaptive strategies and messages that counter the prevailing false narratives and conspiracy theories with community involvement are needed to build confidence about the COVID-19 vaccine and encourage acceptance.

4.1. Limitations

Our study methodology relies on a small sample size to elicit COVID-19 vaccine misinformation and conspiracies theories, perceptions, and intentions about the COVID-19 vaccine. Thus, the findings are not generalizable; instead, they are unique to regions and populations with similar contexts as Nigeria. Despite this limitation, we present important results and messaging recommendations for different regions and sub-groups to improve COVID-19 vaccine acceptance in Nigeria and other comparable contexts.

5. Conclusion

Misinformation and conspiracy theories about COVID-19 vaccination are evident globally. Distrust in the government regarding the pandemic response and suspicion of global actors’ motives regarding the vaccine, especially its effectiveness and safety, is strongly associated with hesitancy. Thus, adaptive strategies and messages are needed in the face of vaccine hesitancy. Targeted awareness campaigns and messages that deliver transparent information about COVID-19 vaccine safety and efficacy and the development process are also needed to encourage vaccine acceptance.

Funding

This study work was supported by Wellcome Trust [Grant Number: 21556/Z/20/Z] to the Johns Hopkins Berman Institute of Bioethics and implemented by Direct Consulting and Logistics. Wellcome Trust was not involved in the study design, data collection, analysis and interpretation, report writing, and the decision to submit the article for publication.

Data statement

All datasets generated and analyzed during the study are available from the corresponding author upon request.

Authors’ contributions

CW led the study development and design, supervised the project implementation, supported data analysis and interpretation, and produced the second and final draft of the manuscript. COJ supported the study design, supervised the project implementation and data collection, led the analysis and interpretation, and developed the first draft of the manuscript. RF, RK, and CK contributed to designing the study, helped with interpreting the analysis, and critically revised the manuscript for important intellectual content. FA, SCKU, TB conducted the data collection and supported the data analysis. RGA supported the data interpretation and critically revised the manuscript for important intellectual content. EFJ supported the study design and data interpretation. All authors approved the final version for submission. RF served as the Principal Investigator, with CW, RK, CK, and COJ as co-investigators.

Declaration of Competing Interest

The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.

Acknowledgments

We acknowledge Dr. Emmanuel Abanida for his contributions and Ms. Kelly Whalen’s invaluable administrative support to the project. We recognize our six implementing partners who provided coordination support for their respective states’ data collection activities. They are Participatory Development Alternatives (Ebonyi State), Basic Foundation for Socio-Economic Development of Rural Women and Youths (Cross River State); Vaccine Network for Disease Control (Federal Capital Territory), Association of OVC NGOs of Nigeria (Gombe State); Mari-Care Foundation for Widows, Single Parents, Orphans and Vulnerable Children (Kano State), and Gender Care Initiative (Lagos). We also recognize our additional data collectors: Winnie David, Ali Racheal, Yahaya Mohammed, Rukayat Bello, Henry Dike Vincent, Arit Egbe, Nsaa Ojagb, Augustine Onwe, Nelson Chibundu, Adeoyese Oyedokun, and Olamide Omigbile, who conducted the qualitative interviews. This study was made possible through a grant from Wellcome Trust, United Kingdom [Grant Number: 21556/Z/20/Z].
