Methodology of including QCD NLO corrections in the quark–gluon Monte Carlo shower is outlined. The work concentrates on two issues: (i) constructing leading order (LO) parton shower Monte Carlo from scratch, such that it rigorously extends collinear factorization into the exclusive (fully unintegrated) one which we call the Monte Carlo factorization scheme; (ii) introducing next-to-leading-order (NLO) corrections to the hard process in this new environment. The presented solution is designed to be extended to the full NLO level Monte Carlo, including NLO corrections not only in the hard process but in the whole shower. The issue of the difference between the factorization scheme implemented in the Monte Carlo (MC) solution and the standard \( \overline{\text{MS}} \) scheme is addressed. The principal MC implementation is designed for the electroweak boson production process at the LHC, but in order to discuss universality – process independence, the deep inelastic lepton–hadron scattering is also brought into the MC framework.

ACKNOWLEDGEMENT

I. INTRODUCTION

The excellent performance and fast experimental data accumulation of the Large Hadron Collider (LHC) at CERN makes the precise evaluation of the strong interactions effects within perturbative Quantum Chromodynamics (QCD) a more and more important task. The principal role of QCD in hadron colliders data analyses (LHC and Tevatron) is to provide precise predictions for distributions and luminosities of quarks and gluons accompanying production of heavy particles.

One of the most important theoretical tools of perturbative QCD (pQCD) are factorization theorems, which formulate any scattering process in QCD in terms of the on-shell hard process part convoluted in the lightcone variable with the ladder parts, provided a single large scale \( Q^{2} \) is involved (short distance interaction). The hard process is usually treated at a fixed perturbative order and the ladder parts are resummed to infinite order, for each coloured energetic ingoing/outgoing parton. The initial state ladders give rise to PDFs, the inclusive parton distribution functions.
The initial state ladder, instead of being source of the inclusive PDF, can be also modelled using Monte Carlo simulation (including hadronization), as initiated in refs. [7, 8]. Such an implementation of the QCD ladder is referred to as the parton shower Monte Carlo (PSMC) program. This kind of programs play an enormous practical role in all collider experiments. In today PSMCs the initial ladders are restricted to the leading order (LO). With growing requirements on the quality and precision of the pQCD predictions for the LHC experiments it becomes urgent to upgrade PSMC to the same next-to-leading-order (NLO) level, which was reached for the inclusive PDFs two decades ago. This is not easy, mainly because factorization theorems of QCD were never meant for the MC implementation. They are well suited for the simpler case of the hard process upgraded with the finite order calculations convoluted with the collinear inclusive PDFs.

There has been, however, a significant progress in implementing pQCD in the framework of PSMC, which started with the work of MC@NLO team and followed by development of POWHEG method. In these works hard process in PSMC is upgraded to the NLO, while the ladder part stays at the LO level, essentially older solutions and software for the LO PSMC are not modified. This, of course, saves a lot of work but because of that the methodology of combining the initial ladder parts and the NLO-corrected matrix element (ME) for the hard process is quite complicated. The solution for this problem is to redesign the basic LO PSMC. This would be too big an investment, if simplification of the NLO corrections to the hard process ME were the only aim. However, this effort is mandatory if we are aiming to upgrade also the ladder parts of PSMC to the complete NLO level.

In this paper we outline a redesigned LO parton shower MC and simultaneously present methodology of including QCD NLO corrections to the hard process which takes advantage of it. Hence we shall concentrate on two issues: (i) constructing once again the LO parton shower Monte Carlo from scratch, such that it is based firmly on the rigorous extension of the collinear factorization theorems, which, contrary to the original collinear factorization, is fully exclusive (unintegrated), (ii) introducing the NLO corrections to the hard process in this new environment. It is natural to expect that the issues of the difference between the factorization scheme implemented in the Monte Carlo (MC) solution and the standard \( \overline{\text{MS}} \) will have to be addressed. The important point of universality (process independence) will be also discussed extensively. Although the principal aim will be a new MC implementation with the LO ladder (upgradable to NLO) and the NLO hard process for the production of the electroweak (EW) boson in quark–antiquark annihilation, in order to address the issue of universality, and for other practical reasons, the deep inelastic lepton–hadron process will be also brought into the consideration. The next step in the project, that is the upgrade of the ladder part to the NLO level, will be treated in a separate publication, although the general method was already outlined in refs. [14]–[16]. Many technical details needed for the NLO ladder are provided in ref. [17] and auxiliary discussions on the soft limit and the choice of the factorization scale in the MC can be found in refs. [18]–[20]. The first numerical tests of the discussed method, of including the NLO hard process corrections, are presented in ref. [21].

Let us note that the ongoing effort undertaken in refs. [22, 23] is in some aspects similar to the present work, in particular the parton shower is also redesigned at the NLO level and the departure from the standard \( \overline{\text{MS}} \) factorization scheme is also advocated. These works are extending/exploiting techniques of refs. [24]–[25].

The remaining part of the paper is organized as follows. In sec. II we discuss collinear factorization in the form suitable for the MC implementation. Section III covers construction of the LO MC for EW boson production and the new method of introducing the NLO corrections to the hard part of this process. In sec. IV we present a similar MC solution for the DIS process, with the new LO MC modelling of the initial and final state ladders and the NLO corrections to the hard process. The issue of the universality as well as factorization-scheme dependence are addressed in various steps of this presentation, with the final discussion in sec. V, where we also summarize and give outlook of further work.

II. GENERALITIES – COLLINEAR FACTORIZATION

![Diagram of parton shower Monte Carlo (PSMC)](Image)

**FIG. 1.** The EGMPR factorization for the EW boson production. Example 2PI kernels for a quark in the forward hemisphere \( K_{\text{fr}} \), an antiquark in the backward hemisphere \( K_{\text{fb}} \) and the hard process part \( C_0 \) are delimited by ellipses. The lower figure highlights the use of cut diagram notation by indicating the amplitude in blue and the complex conjugated amplitude in red.

The precise definition of the LO approximation within factorization of collinear singularities, and the resulting distributions implemented in the Monte Carlo, is a necessary prelude of defining complete NLO distributions, both in the ladder and in the hard process. This is why in the following we shall define a new LO MC, “anchoring” it in the collinear factoriza-
tion theorems \[4 \text{-- } 6\] as firmly as we can.

The production process of electroweak (EW) bosons \( W, Z, \gamma \), in the hadron–hadron scattering, or of other colour-neutral vector particle, will be the object of the interest in the following. We shall refer to it as Drell–Yan (DY) process for short. We are going to describe a Monte Carlo algorithm in which two initial state parton ladders will be modelled up to the LO and the hard process to the NLO level, both the hard and ladder parts in a completely exclusive way. In the construction of the MC we will keep track of the precise relation to the QCD factorization theorems, having in mind that the ladder part (parton shower) will be upgraded to the NLO level in the next step. Diagrammatically, we shall temporarily limit ourselves to the \( C_F^2 \) part in the ladder, that is to gluon bremsstrahlung. Because of copious soft gluon production, this is the most difficult part in the MC construction of the LO (later on of the NLO) MC implementation for the latter. Adding more diagrams (quark–gluon transitions, singlet diagrams) will be discussed briefly, but will be treated in a separate publication.

Let us start from the “raw collinear factorization” formula of ref. \[4\] (in the axial gauge) illustrated in Fig.\[1\] in a standard way (cut diagrams). Following closely notation of ref. \[4\], the standard Feynman amplitude for the heavy boson production process is \( A_{j_F j_B}^{(1)}(p_F, p_B, q_1, q_2, \Gamma) \), where two incoming partons of the type \( j_F \) and \( j_B \) have spin indices \( r_F \) and \( r_B \), heavy boson decay lepton momenta are \( q_i \) and any number of the emitted on-shell gluons and quarks are collectively denoted as \( \Gamma \). Denoting also collectively \( (p_F, p_B, q_1, q_2) \) as \( (p, q) \), the partly integrated cut-diagram is defined as

\[
M_j^{\text{rs}}(p, q) = \sum_{r_F, r_B} A_{j_F j_B}^{(1)}(p_F, p_B, q_1, q_2, \Gamma) A_{j_F j_B}^{\text{qs}}(p, q, \Gamma)^*.
\]

Using the compact matrix notation of refs. \[4 \text{-- } 26\], the above expression in case of two ladders reads

\[
\sigma = C_0 \sum_{n_1, n_2 = 0}^{\infty} K_0^{n_1}(\cdot) K_0^{n_2}(\cdot) C_0,
\]

see also the upper part of Fig.\[1\] for an equivalent graphical representation. In the lower part of Fig.\[1\] the above formula is illustrated diagrammatically using the lowest order bremsstrahlung matrix element where we explicitely indicate the 2PI kernels, with the red part of the diagram representing the conjugate part \( A^* \) of eq. \(1\). Note that in the above expressions phase space of the emitted on-shell partons (cut lines) is integrated over and treated inclusively. In the following discussion it will be explicit and implemented in the Monte Carlo parton shower.

According to ref. \[4\] all collinear singularities in \( \sigma \) of eq. \(2\) are coming from (dressed) propagators between kernels \( K_0 \) along the ladders. The 2PI kernels for the initial quark ladder, \( K_0 \), and the antiquark ladder, \( K_0 \), are expanded to the infinite order, see ref. \[4\]. In the following practical example we shall truncmate them to the (lowest) first order (LO) or to the second order (NLO) \( K_0^{(1)} = K_0^{(2)} = K_0^{(2)} \), taking into account the following \( C_F^2 \) diagrams:

\[
K_0^{(1)} = K_0^{(2)} = \frac{1}{\bar{\alpha}_s} \int \frac{d^4 p}{(2\pi)^4} \frac{1}{p^2} = \frac{1}{2\bar{\alpha}_s} \int \frac{d^4 p}{(2\pi)^4} \frac{1}{p^2}.
\]

A similar expansion up to the 1st order (NLO) is done for the hard process part \( C_0^{(1)} = C_0^{(0)} + C_0^{(1)} \). For simplicity, we are omitting the initial quark and antiquark distributions in the beam hadrons and the flux factor is included in \( C_0 \). The dot “.” in the product \( A \cdot B \) means full phase space integration \( \int d^4 q \) over the lines joining two subgraphs in one ladder.

The next step in the classic works of refs. \[4 \text{-- } 26\] is the introduction of the projection operator \( \Pi \). Its role is to decouple kinematically not only \( C_0 \) and the ladder parts, but the consecutive kernels \( K_0 \) along the ladders, such that the integration over lightcone variables and collinear logs become manifest and ready for analytical calculations. Formally eq. \(2\) gets transformed (at the infinite order) into
where \( A \otimes B \) means convolution in the lightcone variable \( \int dz_1 dz_2 \delta(x - z_1 z_2) A(z_1) B(z_2) \), while integration over transverse momenta is traded into \( \frac{1}{\hat{P}} \) poles of dimensional regularization, (extracted upon integration) by \( \hat{P} \), see ref. [26] for details. The projection operator \( \hat{P} \) used in (4) is slightly different. However, both approaches are incompatible with any MC implementation, as can be seen from the explicit expansion up to NLC\(^1\):

\[
C = C_0 \left(1 - \hat{P} K_{0f}^{[1]} - \hat{P} K_{0b}^{[1]} \right),
\]

\[
\Gamma_f = 1 + \hat{P} K_{0f}^{[1]} + \hat{P} K_{0f}^{[2]} + \hat{P} K_{0f}^{[1]} - \hat{P} K_{0f}^{[1]} - \hat{P} K_{0f}^{[2]} - \hat{P} K_{0f}^{[1]} \tag{4}
\]

\[
\nu(1) = \sigma (1) A \otimes \Gamma_f B = C_0 \left(1 - \hat{P} K_{0f}^{[1]} - \hat{P} K_{0b}^{[1]} \right),
\]

\[
\Gamma_f = 1 + \hat{P} K_{0f}^{[1]} + \hat{P} K_{0f}^{[2]} + \hat{P} K_{0f}^{[1]} - \hat{P} K_{0f}^{[1]} - \hat{P} K_{0f}^{[2]} - \hat{P} K_{0f}^{[1]} \tag{4}
\]

Why? As we see, the above is a mixture of the original phase space integrals like \((K_{0f} - K_{0f})\) and of partly integrated integrals like in \((\hat{P} K_{0f}) \otimes (\hat{P} K_{0f})\). Even if we managed somehow to undo the transverse momentum integrations implicit in \( \hat{P} \) operator, we would still face huge (double logarithmic) oversubtraction in \((\hat{P} K_{0f}) \otimes (\hat{P} K_{0f})\) compensated by \((\hat{P} K_{0f}) \otimes (\hat{P} K_{0f})\), which would be deadly for any MC implementation. For an explicit demonstration of this problem see also the toy model considerations in ref. [27].

The solution of the above over-subtraction problem is well known and already employed in the existing LO parton shower MC since long [17,18] – in short, one has to introduce the time-ordered (T.O.) exponent, see also ref. [28]. Beyond the LO, a collinear factorization formula with T.O. exponent was outlined in ref. [16] and we shall adopt it here. We are going to use it for the LO MC ladders combined with the NLO hard process ME\(^2\). According to ref. [16], eq. (3) is replaced by:

\[
\sigma_{LO} = \sum_{n_1} \sum_{n_2} C_0^{(0)} \left\{ (\hat{P} K_{0f}^{[1]})^{n_1} \right\}_{T.O.} \left\{ (\hat{P} K_{0b}^{[1]})^{n_2} \right\}_{T.O.} \tag{5}
\]

where \( K_{0f}^{[1]} \) is the lowest order (LO) 2PI kernel, the same as in eq. (3), but at the NLO and beyond it is different, see the definition in ref. [16]. The above LO process is depicted in Fig. 2.

As shown in ref. [16], the complete and rigorous definition of the new projection operator \( \hat{P}' \) is not simple. For the present purpose of the two LO ladders and the NLO hard process in the EW boson production we shall define it step by step, starting from the simple cases of zero, one and two gluon ME, \( n_1 + n_2 = 0,1,2 \), rather than defining it immediately in the full form.

Let us denote the Born level differential cross section for the EW vector boson production and decay process, \( q \bar{q} \rightarrow \ell \ell \), as follows:

\[
\frac{d\sigma_B}{d\Omega} (s, \theta).
\]

It may also include non-photonic EW radiative corrections. The above differential cross section is so well known that we may avoid defining its details explicitly. From (two) Feynman diagrams we obtain the following (exact) LO single-gluon emission differential distribution,

\[
d\sigma_1 = \frac{C_F \alpha_s}{\pi} \frac{d\alpha}{d\beta} \frac{d\phi}{2\pi} \times \left[ \frac{d\sigma_{B}(\hat{\theta}, \phi_B) (1 - \beta)^2}{d\Omega} + \frac{d\sigma_{B}(\hat{\theta}, \phi_B) (1 - \alpha)^2}{2d\Omega} \right] d\Omega,
\]

where the Sudakov variables \( \alpha \) and \( \beta \) are defined in Appendix A. This elegant formula is valid for any on/off-shell vector particle production, \( B = \gamma, W, Z \). The polar angles \( \theta_{F,B} \) are defined [29] with respect to \( \vec{p}_{0B} \) and \( \vec{p}_{0F} \) respectively in the rest frame of the \( B \) boson (the rest frame of \( p_{0B} + p_{0B} - k \)).

---

1 Omitting for simplicity quark wave function renormalization.

2 In this work another example of the operator \( \hat{P} \) is presented and also the order in factorizing collinear singularities in eqs. 3 is reversed – it starts from the hard process. Nevertheless, it features the same oversubtraction problems that inhibits MC implementation.

3 Considerations concerning the NLO MC ladder can be found in refs. [15, 17].
Two collinear limits $\beta \to 0$, $1 - \alpha = z = \text{const}$ or $\alpha \to 0$, $1 - \beta = z = \text{const}$ in eq. (6) are manifest. For instance, in the 1st case we have:

$$d\sigma_1 = \frac{C_F \alpha_s}{\pi} \left(\frac{z}{1-z}\right)^\beta \frac{d\varphi}{2\pi} \frac{1+z^2}{2} \frac{d\sigma_B(z, \theta_F)}{d\Omega} d\Omega,$$

that is the LO kernel $P_{qg}(z) = \frac{2C_F \alpha_s}{\pi} \left(\frac{1+z^2}{2(1-z)}\right)$ shows up as expected. Introducing the $P'$ projector in this context may look like an overkill, but it will be instructive to explain how it works in this simple case before going to not so obvious case like an overkill, but it will be instructive to explain how it works in this simple case before going to not so obvious case of multiple use of $P'$ in the following.

The necessary ingredient is a spin projection operator $P_{spin}$, which we define a little bit more rigorously as compared to the Curci–Furmanski–Petrzonio work (CFP) \cite{20}. Our $P_{spin}$ acts definitely before the phase space integration:

$$HP_{spin} K = H_\hat{q} \left[ \frac{\hat{n}}{4n \cdot \hat{q}_i} K, \right.$$

where $\hat{q}_i$ is the on-shell momentum entering the $H$ part, such that it conserves the longitudinal (lightcone) component $n \cdot \hat{q}_i$, and for the axial gauge vector $n$ we may take $n = p_{0B}$ or any other light-like vector, the same for all rungs in a given ladder. The same $n$ is defining transverse polarizations of gluons in the axial gauge and enters a definition of light-like variables $x_i = (nq_i)/(np_{0B})$.

In the present case of a single gluon emission, the action of the $P'$ projector, inserted in the squared, spin summed Feynman diagram\cite{20} between the gluon emission vertex and the $q\bar{q}B$ vertex ($B$ is the EW vector boson) can be summarized as follows:

(a) Apply $P_{spin}$ to decouple a spinor $\gamma$-trace into two parts, the hard ME part and the ladder part.

(b) Apply the explicit upper limit of the phase space for an emitted gluon in the transverse momentum, for example $a < M$, with $a^2 = \beta/\alpha$.

(c) Take the expression for the hard part ME\cite{20} in the collinear limit, $a \to 0$ ($\beta \to 0$) keeping $\alpha = 1 - z = \text{const}$ (or $\alpha + \beta = 1 - z = \text{const}$) and extrapolate it all over the phase space.

(d) Keep unchanged the phase space integration element and its limits.

Point (c) of the above recipe is the most important and requires more discussion. Finding out the limiting collinear expression is trivial, see eq. (7). What is non-trivial is the off-collinear extrapolation (OCEX) of this formula, out of $\beta = 0$ point to all non-collinear phase space. The simplest recipe: go back along $z = 1 - \alpha$ line and use eq. (7)

$$d\sigma_{LO} = \frac{C_F \alpha_s}{\pi} \frac{d\alpha d\beta}{\alpha \beta} \frac{d\varphi}{2\pi} \frac{1+(1-\alpha)^2}{2} \frac{d\sigma_B((1-\alpha)z, \theta_F)}{d\Omega} d\Omega,$$

would be acceptable, provided the Born cross section is flat. In the presence of a narrow resonance in $d\sigma_B(\tilde{s})$, in the $\tilde{s} = s(1-\alpha-\beta) = sz$ variable, this would lead to a disastrous NLO correction $d\sigma_1 - d\sigma_{LO}$, wildly varying over the phase space. This kind of OCEX follows a vertical dashed line in Fig. [3]a.

However, there is a freedom in the off-collinear extrapolation away from $\beta = 0$ point – we may do it also along the line $x = 1 - \alpha - \beta = \text{const}$:

$$d\sigma_{LO} = \frac{C_F \alpha_s}{\pi} \frac{d\alpha d\beta}{\alpha \beta} \frac{d\varphi}{2\pi} \frac{1+(1-\alpha)^2}{2} \frac{d\sigma_B((1-\alpha)z, \tilde{\theta})}{d\Omega} d\Omega.$$

In Fig. [3]a this kind of OCEX goes along the curved dashed line there. The angle $\tilde{\theta}$ has to be also defined within OCEX, in any reasonable way which coincides with the correct value $\theta_B$ at the $\beta = 0$ point\cite{20}. In a sense, the above is fully compatible with the methodology of calculating the NLO corrections to the EW production process in ref. \cite{30} where a lightcone variable of the collinear factorization is also mapped into $x = 1 - \alpha - \beta$. The essential difference is that with the help of OCEX we are replacing the traditional collinear PDF of ref. \cite{30} with the exclusive distribution of eq. (10). A number of consequences of this replacement will unfold gradually in the following.

For easier generalization to two and more gluons, let us formalize slightly the above as:

$$P'_M = \hat{P}'_a \theta_{M>a} P_{spin},$$

where $\hat{P}'_a$ takes collinear limit and implements off-collinear extrapolation on both sides of its location in the Feynman diagrams, without affecting the phase-space integration element.
The rescaled 4-momentum $\tilde{P}$ preserves angles, hence in the MC one may generate $z = \alpha \leq 1$ then construct $\tilde{P}$ and finally rescale it $\tilde{P} = \lambda^{-1} k^\mu$, where $\alpha = \alpha/\lambda$ and $\beta = \beta/\lambda$. The dilatation transformation preserves angles, hence in the MC one may generate $a$ and $\tilde{a} = 1 - z$ according to

$$C_0^{(0)} \mathbb{P}' K_{0F}^{(1)} = \int \frac{d^3 k}{2k^0} \frac{k^0 Q_{0F}(k)}{K_{0F}(k)} \mathbb{P}'_M \int d\tau_2 (P - k; q_1, q_2) C_0^{(0)} (q_1, q_2, k)$$

$$= \int \frac{2C_F}{\pi} \theta_{a < M} \frac{da \, d\phi \, dz}{2\pi} \frac{1 + z^2}{2} d\Omega_q \frac{d\sigma_B(s(1 - \tilde{a}), \hat{\theta})}{d\Omega_q} \theta_{a(1 - a) > 0}.$$  \hspace{1cm} (11)

Note that $z = 1 - \tilde{a} = \delta/s$ is within the proper limits $0 < z < 1$. The above can be formalized by means of introducing the rescaled 4-momentum $\tilde{k}^\mu = \lambda^{-1} k^\mu$.

$$\lambda = \frac{\alpha}{\alpha + \beta} = \frac{\tilde{a}}{\tilde{a} + \beta} \leq 1,$$

which provides exactly the same result as the collinear factorization in these classic works where the 4-momentum conservation is broken. An additional cut-off $a > q_0$ (phase space boundary in the LO MC) was used in the above.

One may also easily define, within the above scheme, a prototype of an universal inclusive collinear PDF:

$$D(M,x) = \mathbb{P}'_M K_{0F}^{(1)} |_{x = 1 - a} = \int \frac{d^3 k}{2k^0} K_{0F}(\tilde{k}) \mathbb{P}'_M \delta_{x = 1 - a}$$

$$= \frac{\ln M}{q_0} \frac{2C_F}{\pi} \frac{1 + x^2}{2(1 - x)},$$ \hspace{1cm} (14)

thanks to $\mathbb{P}'_M$ closing the phase space from the above by means of the factorization scale $M$. As we shall see later on, in the analogous construction for the deep inelastic electron–proton scattering, the role of $\mathbb{P}'_M$ is to map the phase space of the ladder into an idealized phase space of $\tilde{k}^\mu$, decoupled kinematically from the hard process, thus removing process dependence and gaining universality of the ladder part!

\section{NLO correction to hard process – one real gluon}

Having defined the single-gluon ladder parts $C_0^{(0)} \mathbb{P}' K_{0F}^{(1)}$ and $C_0^{(0)} \mathbb{P}' K_{0b}^{(1)}$ in the \textit{exclusive} way, within the same exact

\[ A phase space shape (upper limits) usually depends on the process type. \]

\[ A phase space shape (upper limits) usually depends on the process type. \]
phase space where the complete exact 1-gluon distribution of eq. (6).

\[ D^{[1]} = C_0^{[1]} + C_0^{[0]} \cdot K_0^{[1]} + C_0^{[0]} \cdot K_{0B}^{[1]} \]  \hspace{1cm} (15)

where the \( C_2(x) \) function is calculated in the Appendix B

Note that in the above integral the phase space is covered by the LO distribution completely, without any gap or overlap, provided the factorization scale variable \( M \) in both hemispheres is adjusted conveniently. Similarly, the entire integrand of the NLO correction is also defined all over the 1-gluon phase space.

**B. LO two-gluon \( C_0^{[0]}(p)K_{0f}^{[0]}p\pi K_{0B}^{[0]} \) — a prelude for the LO ladder MC**

Let us take the exact integrated distribution for the ladder diagram (no projections) with two gluons emission

\[ \sigma_2 = C_0^{[0]} \cdot K_{0f}^{[1]} \cdot K_{0B}^{[1]} = \int dx_1 \frac{d^3 k_1 d^3 k_2}{2k_1^0 2k_2^0} d\tau_2 (P - k_1 - k_2; q_1, q_2) \times \rho_B(p_{0f}, p_{0b}, k_1, k_2, q_1, q_2) \delta_{x_1 = (p - k_1)^2} \]  \hspace{1cm} (18)

in which we have introduced explicitly a variable being the effective mass squared

\[ \hat{s}_1 = s_{x_1} = (q_1 + q_2 + k_2)^2 = (P - k_1)^2 \]

of the final state system after emitting the gluon \( k_1 \).

Let us start with the same operation of parametrization of the phase space in terms of \( k_1 = \lambda_1 \hat{k}_1 \) as in the previous case of the single gluon, for a gluon at the end of the ladder:

\[ C_0^{[0]} K_{0f}^{[1]} K_{0B}^{[1]} = \int dx_1 \frac{d^3 \hat{k}_1 d^3 k_2}{2\hat{k}_1^0 2k_2^0} d\tau_2 (P - k_1 - k_2; q_1, q_2) \times \lambda_1^2 \rho_B(p_{0f}, p_{0b}, \lambda_1 \hat{k}_1, k_2, q_1, q_2) \delta_{x_1 = 1 - \lambda_1}, \]

\[ \lambda_1 = \frac{s(1 - x_1)}{2P\hat{k}_1} = \frac{\alpha_1}{\alpha_1 + \beta_1}, \]  \hspace{1cm} (19)

is defined, it is straightforward to define the LO + NLO factorized hard process part in the exclusive (unintegrated) manner:

\[ (C_0^{[0]} + C_0^{[1]}) \left[ 1 + (1 - P^\prime) K_{0f}^{[1]} + (1 - P^\prime) K_{0B}^{[1]} \right] \simeq \]

\[ \simeq C_0^{[0]} + C_0^{[1]} + C_0^{[0]} (1 - P^\prime) K_{0f}^{[1]} + C_0^{[0]} (1 - P^\prime) K_{0B}^{[1]} \]

\[ = C_0^{[0]} + C_0^{[1]} + C_0^{[0]} K_{0f}^{[1]} + C_0^{[0]} K_{0B}^{[1]} - C_0^{[0]} \pi^\prime K_{0f}^{[1]} - C_0^{[0]} \pi^\prime K_{0B}^{[1]} \]

\[ = C_0^{[0]} + D^{[1]} - C_0^{[0]} \pi^\prime K_{0f}^{[1]} - C_0^{[0]} \pi^\prime K_{0B}^{[1]} \]  \hspace{1cm} (16)

The above difference of the exact and approximate ME at the level of the integrand reads

\[ C_0^{[1]} + C_0^{[0]} (1 - P^\prime) K_{0f}^{[1]} + C_0^{[0]} (1 - P^\prime) K_{0B}^{[1]} = D^{[1]} - C_0^{[0]} \pi^\prime K_{0f}^{[1]} - C_0^{[0]} \pi^\prime K_{0B}^{[1]} = \]

\[ = \int d\alpha d\beta d\phi \frac{2C_F \alpha_s}{\pi} \frac{1}{2} \left[ (1 - \beta)^2 d\sigma_B(\hat{s}, \alpha) + (1 - \alpha)^2 d\sigma_B(\hat{\theta}, \beta) \right] \]

\[ - \theta_{\alpha > \beta} \frac{1 + (1 - \alpha - \beta)^2}{2} d\sigma_B(\hat{s}, \hat{\theta}) - \theta_{\alpha < \beta} \frac{1 + (1 - \alpha - \beta)^2}{2} d\sigma_B(\hat{\theta}, \hat{s}) \]  \hspace{1cm} (17)

The factor \( \lambda_1^2 \) from the phase space is compensated by a similar factor in the 1-gluon distribution, as it is for the 1-gluon case. No approximations nor projections are present yet.

Insertion of the first \( P^\prime \) requires examination of the collinear limit \( a_1 \to 0 (\hat{\beta}_1 \to 0) \) keeping \( \alpha_1 = const; \) in this limit we have also \( \hat{\beta}_1 \to 0, \alpha_1 \to \alpha \) and \( \lambda_1 \to 1. \) The spin projection operator of eq. (3) is also used. The collinear limit is well known

\[ \lim_{a_1 \to 0} a_1^2 \rho_B(\lambda \hat{k}_1, k_2, ...) = \frac{1}{\alpha_1^2} \frac{2C_F \alpha_s}{\pi^2} \frac{1 + (1 - \alpha_1)^2}{2} \]

\[ \times \rho_1(x_1 p_{0f}, p_{0b}, k_2, q_1, q_2), \]  \hspace{1cm} (20)

where \( \rho_1 \) is the already discussed distribution of the single-gluon emission \( \rho \) of eq. (6), in the reduced center-of-mass system of \( s x_1 = (x_1 p_{0f} + p_{0b})^2, \) provided we rename \( k \to k_2. \)

The formula obtained above, valid originally at the collinear point \( a_1 = 0, \) is now extrapolated to the off-collinear phase space using \( \hat{k}_1: \)

\[ \hat{\sigma}_1 = \frac{1}{2} \rho_B(p_{0f}, p_{0b}, \lambda \hat{k}_1, k_2, q_1, q_2) \delta_{x_1 = 1 - \lambda_1} \]

\( \lambda_1 = \frac{s(1 - x_1)}{2P\hat{k}_1} = \frac{\alpha_1}{\alpha_1 + \beta_1}, \]
\[ \sigma_{2F} = c_{0}^{(0)} K_{0F}^{(1)} P^\prime K_{0F}^{(1)} \]
\[ = \int dx_1 \frac{d^4 k_1}{2k_1^0} \frac{d^3 k_2}{2k_2^0} \frac{d^2 \tau_2}{1-z} (P - \lambda_1 \bar{k}_1 - k_2; q_1, q_2) \frac{2C_F \alpha_s}{\pi^2} \frac{1 + (1 - \bar{\alpha}_1)^2}{2a_2 \bar{\alpha}_1^2} \rho_1 (x_1 p_{0F}^\prime, p_{0B}^\prime; k_2, q_1, q_2) \delta_{x_1 = 1 - \bar{\alpha}_1} \]
\[ = \int dx_1 \delta_{x_1 = z_1} \frac{C_F \alpha_s}{\pi} \frac{P(z_1) \, d\phi_1 \, d\phi_2}{1 - z_1} \frac{d^2 \tau_3}{a_1} (P - \lambda_1 \bar{k}_1; q_1, q_2, k_2) \rho_1 (z_1 p_{0F}^\prime, p_{0B}^\prime; k_2, q_1, q_2), \]

where the LO splitting kernel for the first emission of \(k_1\)
\[ P_{qq}^{(0)} (z) = \bar{P}(z) = \frac{1 + z^2}{2(1-z)} \]
is factorized off explicitly and the factorization scale for \(P_{M1}^\prime\) is just \(a_{2} = a_2\) of the gluon in the next \(K_{0F}(k_2)\).

This fact that the factorization scale for the first emission is defined to be \(a_{2}\) of the second emission is the essential difference with the standard EGMPR/CFP scheme \([4, 26]\), where \(a_{i} < \mu\) for both emissions and therefore \(a_{2} \to 0\) is not blocked by \(a_1\) like here. The EGMPR arrangement has advantage of being similar to the system of UV subtractions \([26]\) but causes oversubtractions, unfriendly for the MC implementation. We assume implicitly a cutoff regularizing \(a_1 \to 0\) limit, for instance \(a_1 > a_{0}\). Note that, although the distribution of \(a_1\) seems to be simple, we cannot perform \(\int \frac{dx}{a_1}\) to get a pure log, because the upper limit \(a_{2} > a_1\) is still nontrivial; and we have to wait until the next simplifications due to insertion of the second \(P^\prime\), before getting the pure log from the integration.

Let us now insert second \(P^\prime\) into \(c_{0}^{(0)} P^\prime K_{0F}^{(1)} P^\prime K_{0F}^{(1)}\). Again, we examine the limit \(a_{2} \to 0\), keeping \(a_2 / a_{1} = \bar{\alpha}_{2} = const\). While taking this limit we keep \(\bar{\alpha}_{2} = x_1 - x_2 = const\), such that \(\delta = (P - k_1 - k_2)^2 = const\), in addition to previous \(\bar{s}_{1} = const\).

More precisely, we start by introducing
\[ \bar{s} = \bar{s}_{2} = sx = sx_2 = (P - k_1 - k_2)^2 = \bar{s}_{1} - 2(P - k_1) \cdot k_2 \]
as an integration variable:
\[ \sigma_{2F} = \int dx_1 dx_2 \frac{d^4 k_1}{2k_1^0} \frac{d^4 k_2}{2k_2^0} \frac{d^3 \tau_2}{1-z} (P - \lambda_1 \bar{k}_1 - k_2; q_1, q_2) \]
\[ \times \frac{2C_F \alpha_s}{\pi^2} \frac{\hat{P}(1 - \bar{\alpha}_1, \alpha_1)}{a_1 \bar{\alpha}_1} \rho_1 (x_1 p_{0F}^\prime, p_{0B}^\prime; k_2, q_1, q_2) \]
\[ \times \delta_{x_1 = 1 - \bar{\alpha}_1} \delta_{sx - sx_1 + 2(P - k_1) \cdot k_2} \]

Next, we perform the same transformations on \(\delta\)-functions acc-

\[ \text{companied by the rescaling } k_2 = \lambda_2 \bar{k}_2:\]
\[ s\delta(sx_2 - sx_1 + 2(P - k_1) \cdot k_2) \]
\[ = \int dY s\delta(sx_2 - sx_1 + 2(P - k_1) \cdot k_2) Y^{-2} 2p_{0B} \cdot k_2 \]
\[ \times \delta(sx_2 - sx_1 + 2p_{0B} \cdot k_2) Y^{-1} \]
\[ = \int dY s\delta(sx_2 - sx_1 + 2(P - k_1) \cdot Y \bar{k}_2) Y^{-2} 2p_{0B} \cdot \bar{k}_2 \]
\[ \times \delta(sx_2 - sx_1 + 2p_{0B} \cdot \bar{k}_2) \]
\[ = \frac{\lambda_2^{-1} 2p_{0B} \cdot \bar{k}_2}{2(P - k_1) \cdot k_2} \delta(sx_2 - sx_1 + \frac{2p_{0B} \cdot \bar{k}_2}{s}) \]
\[ = \delta(sx_2 - sx_1 + \frac{2p_{0B} \cdot \bar{k}_2}{s}) \delta_{x_1 - x_2 = \bar{\alpha}_2}, \]
\[ \text{where} \]
\[ \lambda_2(\bar{k}_1, \bar{k}_2) = \frac{s(x_1 - x_2)}{2(P - k_1) \cdot k_2} = \frac{s(x_1 - x_2)}{2(P - \lambda_1(1) k_1) \cdot k_2}. \]
\[ \text{Note that the scaling factor } \lambda_2 \to 1 \text{ in the collinear limit } \bar{\beta}_2 \to 0. \]

Let us stress that the integral under consideration is now transformed into a new equivalent form, but the limit \(a_{2} \to 0\) is yet to be taken! In the transformed variables the integral reads
\[ \sigma_{2F} = \int dx_1 dx_2 \frac{d^4 k_1}{2k_1^0} \frac{d^4 k_2}{2k_2^0} \frac{d^3 \tau_2}{1-z} (P - \lambda_1 \bar{k}_1 - \lambda_2 \bar{k}_2; q_1, q_2) \]
\[ \times \frac{2C_F \alpha_s}{\pi^2} \frac{\hat{P}(1 - \bar{\alpha}_1, \alpha_1)}{a_1 \bar{\alpha}_1} \lambda_2^2 \rho_1 (x_1 p_{0F}^\prime, p_{0B}^\prime; \lambda_2 \bar{k}_2, q_1, q_2) \]
\[ \times \delta_{x_1 = 1 - \bar{\alpha}_1} \delta_{sx - sx_1 - 2(P - k_1) \cdot k_2}. \]
\[ \text{Now we are ready to take the limit } a_{2} \to 0 \text{ keeping } a_1 / a_{2} = \bar{\alpha}_{2} = const \text{ (also } a_0 \to 0) \text{ and } \bar{\alpha}_{1} = const:\]
\[ c_{0}^{(0)} P^\prime K_{0F}^{(1)} P^\prime K_{0F}^{(1)} = \]
\[ = \int dx_1 dx_2 \frac{d^4 k_1}{2k_1^0} \frac{d^3 k_2}{2k_2^0} \frac{d^3 \tau_2}{1-z} (P - \lambda_1 \bar{k}_1 - \lambda_2 \bar{k}_2; q_1, q_2) \]
\[ \times \frac{2C_F \alpha_s}{\pi^2} \frac{\hat{P}(x_1)}{a_1^2 \bar{\alpha}_1^2} \frac{2C_F \alpha_s}{\pi^2} \frac{\hat{P}(x_2 / x_1)}{a_2^2 \bar{\alpha}_2^2} \frac{d\sigma_B}{d\Omega} (sx_2, \bar{\theta}) \]
\[ \times \delta_{x_1 = 1 - \bar{\alpha}_1} \delta_{x_2 = 1 - \bar{\alpha}_2}. \]
\[ \text{Note that the } \lambda_2^2 \text{ factor from the phase space and the matrix element cancels out as before. The above formula is the principle result of this subsection. It defines the double use of} \]

\[ ^{9} \text{Here } C_{0}^{(0)} \text{ is the interference term, while the other two terms are amplitude squares.} \]
The undoing is "effective", because the kinematical projection of refs. [4, 10] is particularly the following lessons are to be learnt:

\[ C_0^{(0)} P' K_{0F}^{(1)} P' K_{WF}^{(1)} = \frac{1}{2!} \ln^2 \frac{M}{m_0} \left( \frac{2 C_F \alpha_s}{\pi} \right)^2 \]

\[ C_0^{(0)} P' K_{0F}^{(1)} P' K_{WF}^{(1)} = \frac{1}{2!} \ln^2 \frac{M}{m_0} \left( \frac{2 C_F \alpha_s}{\pi} \right)^2 \]

\[ \times \int_0^1 dx [P_{qq} \otimes P_{qq} ]_{2R}(x) \sigma_B(x), \]

where

\[ 4 [P_{qq}^{(0)} \otimes P_{qq}^{(0)} ]_{2R}(z) = 1 + \frac{z^2}{1 - z} \left[ 4 \ln \left( \frac{1}{\delta} \right) + 4 \ln(1 - z) \right] \]

\[ + (1 + z) \ln z - 2(1 - z) \]

is just a double convolution of the LO kernel with the IR regularization \( \alpha_s > \delta \).

The distribution of eq. (25) is easy to generate in the Monte Carlo. First, one generates \( a_i \) and \( \alpha_i \), paying attention to the constraint \( x = x_2 = 1 - \alpha_1 - \alpha_2 \), and \( \bar{k}_i \) are constructed in the laboratory frame. Then \( \lambda_i \) are calculated and the rescaling \( \bar{k}_i \to k_i \) is done (in two steps!). Finally, in the frame \( \vec{P} = k_1 - k_2 \) one generates \( g_i \) according to the Born differential distribution. The phase space boundary \( \delta \geq 0 \) is obeyed automatically. In the MC the soft IR regulator \( z_i = x_i/x_{i-1} < 1 - \delta \) will be introduced and the overall virtual Sudakov form-factor \( \exp \left( - \frac{2 C_F \alpha_s}{\pi} \ln \frac{m}{m_0} \ln \frac{\delta}{\delta_0} \right) \) will also be supplemented.

The above example demonstrates the most important features of the \( P' \) projector (see ref. [16] for more details). In particular the following lessons are to be learnt:

(a) The phase space parametrization \( k_i \to \bar{k}_i \) plays an important role in \( P' \), as it is instrumental in implementing off-collinear extrapolation, and also helps to take the collinear limit in the first place.

(b) The rescaled 4-momenta \( \bar{k}_i \) violate the 4-momentum conservation, similarly like 4-momenta after action of the kinematical projector of refs. [4, 27]. In our case, however, the off-collinear extrapolation is effectively undoing this kinematical projection[11] and allows to operate in the original phase space, with the 4-momentum conservation untouched.

(c) A nice accident of the Jacobian \( |\partial(\bar{k}_1, \bar{k}_2)/\partial(k_1, k_2)| \) being compensated by the matrix element is generally not guaranteed. However, if it were not true, we would have to impose this by hand, such that a pure logarithm results from the phase space integration, like in eq. (26), similarly as in the definition of the collinear counterterm in refs. [9, 31], for example.

(d) The role of the parametrization \( k_i \to \bar{k}_i \) in assuring universality (process-independence) of the ladder parts will be clarified once the MC for the DY and DIS processes with the NLO corrections to the hard part are defined, see below.

(e) The phase space parametrization in terms of \( \bar{k}_i \) will be used also inside \( K_0 \) to parametrize the two-gluon phase space, for instance for the 2-gluon crossed diagram in the NLO ladder.

(f) The soft eikonal limit is protected by \( P' \), because rescaling \( \bar{k}_i \to k_i \) preserves it.

For a better (complete) understanding of the construction of \( P' \) one needs to examine in a fine detail the case of two gluons in the middle of the ladder, for instance in \( C_0^{P'} K_{0F}^{(1)} K_{WF}^{(1)} P' \), which provides the NLO correction to the evolution kernel.

III. MONTE CARLO FOR EW BOSON PRODUCTION

The insertion of the \( P' \) operator into the LO gluonstrahlung ladder with any number of gluons can be done similarly as in Sec. IIIB obtaining the distribution ready for the LO MC modelling of the production process of the EW boson with multiple gluons emitted from the incoming quarks.

A. Simplified single ladder case

We start with the gluonstrahlung ladder just in one hemisphere in order to avoid algebraic complications of the two-ladder case (to be dealt with in the next subsection):

\[ C_0^{(0)} \cdot \Gamma_F = \sum_{n=1}^{\infty} \left\{ C_0^{(0)} (P') K_{WF}^{(1)} \right\}_n \]

\[ = e^{-S_F} \sum_{n=0}^{\infty} \int_{\theta_{<}} d^2 \varepsilon(\vec{k}_i) \theta_{<} \eta_{<} \left( \frac{2 C_F \alpha_s}{\pi} \right) \int_{\theta_{<}} d^2 \varepsilon(\vec{q}_2) \theta_{<} \eta_{<} \sum_{j} \frac{d\sigma_R}{d\Omega} (sx, \hat{\theta}), \]

\[ \times d\tau_2 \left( P - \sum_{j} k_j, q_1, q_2 \right) \theta_{<} \eta_s \delta_{<} \left( \sum_{i} \bar{k}_i \right) \frac{d\sigma_R}{d\Omega} (sx, \hat{\theta}), \]

\[ (27) \]

10 With our phase space parametrization in terms of \( \bar{k}_i \) the above mechanism of producing pure logs is a general phenomenon, because \( M \) is always at the end of the ladder, and the ladder has a built-in time-ordered exponential.

11 The undoing is "effective", because the kinematical projection of refs. [4, 27] in our methodology is never done. A clever parametrization of the phase space is the only thing really done.

12 This task is pursued in separate works [13, 14].
In the above we understand that the F part is the forward part
phase space–integration element
soft
the IR-boundary \( \bar{\lambda} \), see the definitions of
T
a significant
later on.
(maximum rapidity for gluons in the B hemisphere). For the
scale, see ref. [16] for a general definition. The
for the time-ordering exponential structure in the factorization
scale, see ref. [16] for a general definition. The \( S_F \) function is
the usual MC Sudakov form-factor depending on the shape of
the IR-boundary \( \bar{\alpha}_n \rightarrow 0 \). Factorization scale is now defined
as the minimum rapidity \( \Xi \) for gluons in the F hemisphere
(maximum rapidity for gluons in the B hemisphere). For the
moment \( \Xi \) is a free parameter, to be defined more precisely
later on.

Note that the definition of \( \bar{\lambda}_i \) is recursive, that to define
\( \lambda_i \) one must know \( \lambda_{i-1} \). In a typical MC event first \( \lambda \)'s,
corresponding to very collinear gluons will be very close to one,
\( \lambda_i \approx 1 \); only the last ones corresponding to non-collinear non-
soft gluons, i.e. close to the hard process, will be rescaled by
a significant \( \lambda_i \neq 1 \) factor.

Similarly as in the case of two gluons in eq. [26], the trans-
verse integration decouples and is feasible analytically:
\[
C_0^{(0)} \cdot \Gamma_F = \int_0^1 dx \ G_F(M,x) \ \sigma_B(xx),
\]
\[
G_F(M,x) = e^{2 \alpha_F \Delta \ln \frac{1}{2} M \ln \frac{M}{q_0}} \times \left\{ \delta_{\xi=1} - \sum_{n=1}^{\infty} \frac{1}{n!} \left( \frac{2 \alpha_F \Delta}{\pi} \right)^n \ln^2 \frac{M}{q_0} \right\},
\]
where the IR regularization \( (1 - z_i) < \Delta \) is used in the \( n \)-times
convolution of the LO kernel \( [P_{qq}^{(0)}]^{\otimes n} \). It should be stressed
that the above LO formula represents the LO MC without any
approximation.

The inclusive (bare) PDF \( G_F(M,x) \) of the MC obeys by
construction the LO evolution equation:
\[
\frac{\partial}{\partial \ln M} G_F(M,x) = [P_{qq}^{(0)} \otimes G_F(M)](x),
\]
where \( P_{qq}^{(0)}(z) = \frac{2 \alpha_F \Delta}{\pi} \left[ \frac{1+2z}{2(1-z)} \right] \). This is essentially due to
the use of the T.O. exponent in eq. [27].

**B. Two ladder LO case**

Let us now consider the case of two ladders. In the back-
ward (B) hemisphere \( x_i \) are related to \( \bar{\beta}_i \) (instead of \( \bar{\alpha}_i \)), the
evolution runs towards larger rapidity, otherwise all algebraic
structure is the same. Again, we first express the LO MC master
formula in terms of rescaled 4-momenta \( \hat{k}_i = \lambda_i k_i \), but we
postpone the definition of \( \lambda_i \), as it will be a little bit special.
We propose the following multigluon distribution to be imple-
ment in the LO approximation\(^{[13]}\):

\[
C_0^{(0)} \cdot \Gamma_F = \sum_{n_1=1}^{\infty} \sum_{n_2=1}^{\infty} \int_{0}^{1} \int_{0}^{1} e^{-S_B} \int_{\Xi < \eta_{F1}} \left( \frac{2 \alpha_F \Delta}{\pi^2} \bar{P}(\bar{z}_{F1}) \right) \delta_{\eta_{F1} > \eta_{B1}} \ d\tau_1 \left( P - \sum_{j=1}^{n_1+n_2} \hat{k}_j, q_1, q_2 \right) \frac{d\sigma_B}{d\Omega}(sx_F \cdot B, \bar{\theta}).
\]

\( C_0^{(0)} \cdot \Gamma_B = \sum_{n_1=1}^{\infty} \sum_{n_2=1}^{\infty} \int_{0}^{1} \int_{0}^{1} e^{-S_B} \int_{\Xi > \eta_{B2}} \left( \frac{2 \alpha_F \Delta}{\pi^2} \bar{P}(\bar{z}_{B2}) \right) \delta_{\eta_{B2} > \eta_{B2}} \ d\tau_2 \left( P - \sum_{j=1}^{n_1+n_2} \hat{k}_j, q_1, q_2 \right) \frac{d\sigma_B}{d\Omega}(sx_B \cdot B, \bar{\theta}).
\]

In the above we understand that the F part is the forward part
of the phase space \( \eta_{0F} > \eta_i > \Xi \) and the B part is the backward
part \( \Xi > \eta_i > \eta_{0B} \). The rapidity boundary \( \Xi \) between the F

**13** The reader should keep in mind that the above is for the “primordial” quark
and antiquark initial beams, and their distributions in hadron will be added
in the MC program.

**14** In practice the choice of \( \Xi \) may be quite complicated, for instance it can
be correlated with the rapidity position of the EW boson. In the NLO
the single hemisphere case, provided we perform kinematical mappings asymmetrically, first in one hemisphere and then in the other one. We shall do it below, however, in a more sophisticated symmetric way. The definition of $z_{F_i}$ and $z_{B_j}$ will result from that.

The angle $\hat{\theta}$ can be defined with respect to any reasonable $z$-axis in the rest frame of $P - \sum k_j$, for instance along $\hat{p}_{0F} - \hat{p}_{0B}$ in this frame. The boundary between the F and B phase space is at the rapidity $\Xi$. It is also understood that the differential cross section of eq. (30) is explicitly convoluted with some initial quark distributions at $\eta_{0F}$ and $\eta_{0B}$ and the appropriate boost is done from the reference frame of the quark–antiquark frame $p_{0F} + p_{0B}$ to the laboratory frame.

Again, in eq. (30), phase space can be integrated analytically over transverse momenta, providing the classical factorization formula

$$C_0^{(i)} F_1^{(i)} \Gamma_B^{(i)} = \int_0^1 dx_F dx_B G_F(\Xi, x_F) G_B(\Xi, x_B) \sigma_B(s x_F x_B), \quad (31)$$

where $G_B(\Xi, x) = G_F(\Xi, x)$. The remarkable feature is that the above LO formula represents the exact LO MC without any approximations!

We could define the dilatation parameters $\lambda_i$ (recursively) first for one ladder and then for the other, but this solution would be asymmetric. Instead, we define the dilatation parameters in $k_i = \lambda_i \tilde{k}_i$ in a more sophisticated way, for both hemispheres simultaneously. For that purpose we introduce a new ordering (indexing) of gluons according to the distance $|\eta_i - \Xi|$ from the rapidity $\Xi$ of the EW boson. Formally, we define a permutation

$$\pi = \{\pi_1, \pi_2, \ldots, \pi_{n_1 + n_2}\}$$

of all gluons in the F+B phase space, such that

$$|\eta_{\pi_i} - \Xi| > |\eta_{\pi_{i-1}} - \Xi|, \quad i = 1, \ldots, n_1 + n_2,$$

With the help of the above simultaneous “double ordering” in the F and B hemispheres, we define in a recursive way:

$$k_{\pi_i} = \lambda_i \tilde{k}_{\pi_i}, \quad \lambda_i = \frac{s(x_{i-1} - x_i)}{2P - \sum_{j=1}^{i-1} k_{\pi_j} \cdot \tilde{k}_{\pi_j}}, \quad i = 1, 2, \ldots, n_1 + n_2, \quad (32)$$

where $x_i$ now is

$$x_i = \prod_{j=1}^{i} z_{(F,B)\pi_j},$$

where $(F,B)$ means that we insert in the above product either $z_{F_j}$ or $z_{B_j}$, depending whether $\pi_j$ points to the F or B region.

The parameter $\lambda_i$ is defined in eq. (32) recursively by means of solving the following equation

$$\tilde{s}_i = s x_i = (P - \sum_{j=1}^{i} k_{\pi_j})^2 = (P - \sum_{j=1}^{i} \lambda_j \tilde{k}_{\pi_j})^2.$$
C. Real NLO correction to hard process

The NLO correction in the EW boson production hard process (non-singlet) will be implemented using a single “monolithic” MC weight, which reweighs the LO distributions defined in the previous subsection. The real emission part of the NLO correction in this weight comes from the integrand of eq. (17) which we rewrite as follows:

$$C^{[1]} = C_0^{[1]} + C_0^{[0]} (1 - \Pi') K_F^{[1]} + C_0^{[0]} (1 - \Pi') K_{0B}^{[1]} = \int d^3 E (k) \, d\Omega_q \, 2C_F \alpha_s \beta_1 (\hat{p}_F, \hat{p}_B, q_1, q_2, k);$$

$$\tilde{\beta}_1 (\hat{p}_F, \hat{p}_B, q_1, q_2, k) = \left[ \frac{(1 - \beta)^2}{2} \frac{d\sigma_B}{d\Omega_q} (\hat{\delta}, \hat{\theta}_F) + \frac{(1 - \alpha)^2}{2} \frac{d\sigma_B}{d\Omega_q} (\hat{\delta}, \theta_B) \right]$$

$$- \theta_{\alpha \beta} \left[ \frac{1}{2} \frac{d\sigma_B}{d\Omega_q} (\hat{\delta}, \hat{\theta}_F) + \frac{1}{2} \frac{d\sigma_B}{d\Omega_q} (\hat{\delta}, \hat{\theta}_F) \right].$$

In the following use of function \( \tilde{\beta}_1 (\hat{p}_F, \hat{p}_B, \ldots) \), defined in eq. (33), vectors \( \hat{p}_F \) and \( \hat{p}_B \) (\( \hat{p}_{FB} = 0 \)) result from the last insertion of \( \Pi' \) before the hard process and they are defined in the rest frame of \( \hat{p} = q_1 + q_2 \) to determine \( F = \angle (\hat{q}_1, \hat{p}_{0F}) \) in the LO part of the Born cross section. On the other hand, angles \( \theta_F \) and \( \theta_B \) are defined with respect to the original \( -\hat{p}_{0B} \) and \( \hat{p}_{0F} \) in this frame. They will all coincide when all gluons get collinear.

The distribution of the MC with the LO+NLO hard process is now defined as follows:

$$C^{(1)} \Gamma_F^{(1)} k_B = \sum_{n_1=0}^{\infty} \sum_{n_2=0}^{\infty} \int dxf \, dx_b$$

$$\times e^{-S_F} \int_{\eta_{n_1}} \left( \prod_{i=1}^{n_1} \left[ \sum_{j=1}^{m_1} d^3 E (k_i) \theta_{n_i, q_1, q_2} \frac{2C_F}{\pi^2} \hat{p}(z_{F,i}) \right] \right) \delta_{x_F = [1, z_{F,i}]}

\times e^{-S_B} \int_{\eta_{n_2}} \left( \prod_{j=1}^{n_2} \left[ \sum_{j=1}^{m_2} d^3 E (k_j) \theta_{n_j, q_1, q_2} \frac{2C_F}{\pi^2} \hat{p}(z_{B,j}) \right] \right) \delta_{x_B = [1, z_{B,j}]}

\times d^2 \tau \left( p - \sum_{j=1}^{n_1+n_2} k_j; q_1, q_2 \right) \frac{d\sigma_B (x_F x_B, \hat{\theta}, \hat{\delta})}{d\Omega} W_{MC}^{NLO},$$

where the MC weight is

$$W_{MC}^{NLO} = 1 + \Delta g + \sum_{j \in F} \tilde{\beta}_1 (\delta, \hat{p}_F, \hat{p}_B, q_1, q_2, z_{F,j})$$

$$+ \sum_{j \in B} \tilde{\beta}_1 (\delta, \hat{p}_F, \hat{p}_B, q_1, q_2, z_{B,j})$$

$$+ \sum_{j \in B} \tilde{\beta}_1 (\delta, \hat{p}_F, \hat{p}_B, q_1, q_2, z_{B,j})$$

with the NLO soft+virtual correction \( \Delta_{NLO} \) to be defined separately in the following subsection.

Our construction of the above MC weight of eq. (35) is quite similar to that proposed in ref. [35] for the NLO corrections in the middle of the ladder [18]. The difference is that the proposal of ref. [35] was based entirely on the Bose–Einstein symmetrization of the multigluon emission in the LO MC and the resulting weight was more complicated, while the MC weight of eq. (33) is significantly simpler and algebraically similar to that of ref. [36] (albeit for the collinear rather than soft gluon resummation).

The meaning of the arguments in \( \tilde{\beta}_1 \) is such that in eq. (33) \( \delta = s_{XFEB}, \) and three angles \( \theta_F, \theta_B, \) and \( \theta_B \) have already been explained above. What remains to be specified is the definition of \( \alpha_j \) and \( \beta_j \) in terms of the variables \( a_j, z_j \) in \( j \in F, B \) parts of the phase space as follows:

$$\alpha_j = 1 - z_{F,j}, \quad \beta_j = z_{B,j}/a_{z,j}, \quad \text{for } j \in F,$$

$$\beta_j = 1 - z_{B,j}, \quad \beta_j = z_{B,j}/a_{z,j}, \quad \text{for } j \in B,$$

where the rapidity \( \eta_j \) is translated properly into \( a_j \) and the rapidity \( \Xi \) corresponds to \( a_2 \).

As compared to earlier attempts to consistently implement the NLO corrections to the hard process in the parton shower MC, the proposals of refs. [34] [32] were going in a similar direction. However, the present work differs from these works in three important points: (i) the virtual corrections \( \Delta_{SV} \) are added here, (ii) the method of combining the NLO correction with the LO MC proposed here is systematic and NLO-complete, (iii) the treatment of the kinematics is compatible with the principles of the collinear factorization.

Comparison of our methodology with the well established methods of MC@NLO [9] and POWHEG [11] is done in section [12].

D. NLO analytical factorization formula

For the LO MC defined in eq. (30) we have seen that without compromising the exact phase space for multiple gluons (keeping the 4-momentum conservation) we could get the contributions of ladder parts factorizing off, exactly as in the traditional collinear factorization (in which the 4-momentum is not conserved). The above seems to be almost miraculous in view of the complicated nature of the exact complete phase space and the fact that no approximation was done.
What is even more amazing is that the same nice exact factorization is also true for the MC with the NLO-corrected hard process included according to eq. (34). The key point is that analytical integration of the phase space, again without any approximation, in eq. (34) is feasible (!) and leads to a simple familiar result

$$C(1)\bar{\Gamma}_F(1)\Gamma_B^{-1} = \int_0^1 dx_F\, dx_B\, dx\, G_F(\Xi, x_F)\, G_B(\Xi, x_B)\times\sigma_B(szx, x_B) \left\{ \delta_{\epsilon=1}(1+\Delta_{\epsilon, V}) + C_2(z) \right\},$$

(36)

where $C_2(z) = 2\alpha_s \left[ -\frac{1}{2}(1-z) \right]$, see Appendix B. Two LO PDFs, $G_F(\Xi, x_F)$ and $G_B(\Xi, x_B)$ are these of eq. (31). The algebraic proof of the above formula can be found in Appendix C.

Note that the LO PDFs, $G_{F,B}(\Xi, x)$, are by construction in the collinear factorization scheme specific for the MC, it will be the same in the MC for the DIS process – the scheme dependence of physical observables will cancel as usual, for instance while transferring experimental knowledge on the parton distributions from the DIS process to the DY process (or vice versa).

Let us comment on the $z$-dependent $C_2(z)$ term in eq. (36), since it is different from what we see in ref. [30] where it is simply absent. It is not present there because it is compensated by the twin terms $\sim -\frac{1}{2}\epsilon(1-z)\frac{1}{2}(1-z)$ originating from the $\gamma$-traces and located at $y = \pm 1$, that is exactly at the collinear poles (for gluon strictly parallel with the quark). This cancellation is not disturbed by the $\overline{MS}$ collinear counterterm subtraction. In our MC factorization scheme this term is included in the counterterm, hence the net contribution from one of these terms, contrary to $\overline{MS}$, stays unc cancelled in eq. (36).

E. NLO soft+virtual corrections

Let us consider the unsubtracted results of Altarelli–Ellis–Martinelli (AEM) work [30] in which real and virtual 1-gluon emission diagrams are combined and integrated over the phase space, keeping the variable $z = x = z/s = 1 - \alpha - \beta$ under control:

$$\sigma_{dy}^{\text{AEM}} = \int_0^1 dz\, f_{dy}^{\text{AEM}}(z)\, \sigma_B(z),$$

$$f_{dy}^{\text{AEM}}(z) = \delta(1-z) + \delta(1-z)\frac{C_F\alpha_s}{\pi}\left(\frac{2}{3}\pi^2 - \frac{7}{4}\right) + 2\frac{C_F\alpha_s}{\pi}\left(\frac{\hat{s}}{\mu^2}\right)^\varepsilon\left(\frac{\hat{P}(z)}{1-z}\frac{1}{\varepsilon} + \frac{1}{\varepsilon} + \omega_2\right) + \frac{C_F\alpha_s}{\pi}\left(4\hat{P}(z)\ln\left(1-z\right) - 2\hat{P}(z)\ln\left(1-z\right)\right),$$

(37)

where $\hat{P}(z) = \frac{1}{2}(1 + z^2)$, $\omega_2 = \gamma_E - 4\pi$ and the incoming quark and antiquark are massless and on-shell. The NLO real 1-gluon emission distribution entering in the above AEM result is identical to $d_{dy}^{1}(1-z)$ and $\sigma_{dy}^{\text{AEM}}$ includes the complete (gluonstrahlung) virtual corrections, including the quark wave–function renormalization constant $Z_F$. Since $\sigma_{dy}^{\text{AEM}}$ is gauge invariant, the calculation of eq. (37) is done in ref. [30] in the convenient Landau gauge [27].

In the formal standard $\overline{MS}$ methodology one subtracts from $f_{dy}^{\text{AEM}}(z)$ two LO collinear counterterms

$$K_{F}^{\overline{MS}}(z) + K_{B}^{\overline{MS}}(z) = 2K_{F}^{\overline{MS}}(z) = 2\frac{C_F\alpha_s}{\pi}\left(\frac{\hat{P}(z)}{1-z}\right)\frac{1}{\varepsilon},$$

(38)

in order to avoid double counting with the ladder and/or experimental PDF, thus obtaining $C_0(1 - \ln P_{eK/d} - \ln P_{eK_0})$. This gives rise to the standard subtracted DY analog of the DIS coefficient function in the $\overline{MS}$ scheme

$$f_{dy}^{\text{MS}}(z) = f_{dy}^{\text{AEM}}(z) - K_{F}^{\overline{MS}}(z) + K_{B}^{\overline{MS}}(z) = \delta(1-z) + \delta(1-z)\frac{C_F\alpha_s}{\pi}\left(\frac{2}{3}\pi^2 - \frac{7}{4}\right) + 2\frac{C_F\alpha_s}{\pi}\left(\frac{\hat{P}(z)}{1-z}\frac{1}{\varepsilon} + \frac{1}{\varepsilon} + \omega_2\right) + \frac{C_F\alpha_s}{\pi}\left(4\hat{P}(z)\ln\left(1-z\right) - 2\hat{P}(z)\ln\left(1-z\right)\right),$$

(39)

Note that the $\ln\frac{\hat{s}}{\mu^2}$ term in the above will be absent if the relation $\hat{s} = \mu^2 e^{-\alpha_2}$ is adopted as in refs. [39, 40]. It is well known [30] that the numerically dominant term $\ln\left(1-z\right)$ in the above function is correcting for the misrepresenting of the soft gluon behaviour and incorrect phase space limits of the $\overline{MS}$ dimensional regularization (subtraction) scheme. In our MC scheme this term will not be present (gets transferred to the ladder).

The plus regularization $(\ldots)_+$ of the IR singularity in eq. (38), in the diagrammatic approach of the CFP [25], comes from $Z_F$ in the axial gauge. It is also shown by CFP that there is a diagram-per-diagram correspondence between Feynman

19 A quite similar formula for introducing the NLO correction to the LO kernel in the middle of the ladder was already tested numerically in the MC exercise with 4-digit precision, see ref. [15].
20 It is also absent in QED, in the well known formula of Bonneau–Martin [38].
21 See eq. (89) there.
In the context of the subtraction/factorization scheme aligned with the MC, we should apply eq. (17), that is in order to avoid double counting with the ladder (PDF), we should subtract from eq. (6) the LO contribution of the MC:

$$\rho_{1F_\gamma}(\alpha, \beta) = \frac{1}{\beta} \frac{C_F \alpha_s}{\pi} \frac{(1 - \alpha - \beta)}{\alpha} \theta_{\beta < \alpha}. $$

However, in order to combine it properly with the virtual corrections, the above distribution should be extrapolated to $n = 4 + 2\varepsilon$ and integrated over the phase space. This is done for the F hemisphere in the following (keeping in mind that $1 - \alpha - \beta = 1 - \bar{\alpha}$):

expanded Sudakov form-factor (of the LO MC reads:

$$K_F^{\mathrm{MC}}(z, \varepsilon) = \frac{C_F \alpha_s}{\pi} \int \frac{d\alpha d\beta}{\alpha \beta} \int d\Omega_{2+2\varepsilon} \left( \frac{s d\hat{\beta}}{\mu^2} \right)^\varepsilon P(1 - \alpha, 1 - \beta) \theta_{\beta < \alpha} \delta_{\theta = 1 - z} \ S_{\mathrm{MC}}(s, \varepsilon) $$$$ = \frac{C_F \alpha_s}{\pi} \left( \frac{s}{\mu^2} \right)^\varepsilon \left( \frac{\Omega_{2+2\varepsilon}}{\varepsilon} \right) \left( \frac{P_{\gamma}(z, \varepsilon)}{1 - z} \right) \left( \frac{1}{\varepsilon} + \omega_2 + \ln \frac{s}{\mu^2} \right), $$

where the $O(\varepsilon)$ contribution from $\gamma$-trace is added to the LO kernel

$$\tilde{P}_\gamma(z, \varepsilon) = \tilde{P}(z) \left( 1 + 2\varepsilon \ln(1 - z) \right) + \frac{1}{2}\varepsilon(1 - z)^2,$$$$

$$\tilde{P}(z, \varepsilon) = \tilde{P}(z) + \frac{1}{2}\varepsilon(1 - z)^2.$$ The overall plus-prescription is coming from the 1st order expansion of the Sudakov form-factor in the MC in $n = 4 + 2\varepsilon$ dimensions and from the usual sum rule $\int d\varepsilon K^{\mathrm{MC}}_F(z, \varepsilon) = 0$ (treating $\hat{s}$ as $\varepsilon$-independent):

$$S_{\mathrm{MC}}(\hat{s}, \varepsilon) = \frac{C_F \alpha_s}{\pi} \frac{\Omega_{2+2\varepsilon}}{\varepsilon} \int_0^{1 - \hat{s}} d\varepsilon \left( \frac{P(z, \varepsilon)}{1 - z} \right)^{1 - 2\varepsilon} \left( \frac{\hat{s}}{\varepsilon^2} \right)^\varepsilon,$$$$

with both $O(\varepsilon)$ terms in $\tilde{P}(z, \varepsilon)$ necessarily participating in the $\langle \cdots \rangle_\varepsilon$ prescription.

The expression of eq. (37) is the result of the following phase space integration

$$f_{DY}^{\mathrm{AEM}}(z, \varepsilon) = \frac{C_F \alpha_s}{\pi} \int \frac{d\alpha d\beta}{\alpha \beta} \int d\Omega_{2+2\varepsilon} \left( \frac{s d\hat{\beta}}{\mu^2} \right)^\varepsilon \cdots \rho_1(\alpha, \beta) \delta_{\theta = 1 - z} \ U_{S + V},$$

where $\rho_1(\alpha, \beta)$ is the one real gluon distribution and $U_{S + V}$ sums up the real soft gluon, $\alpha + \beta > \delta$, and vertex virtual contribution. The complete 1-gluon contribution (including the

24 In this sense the axial gauge is implicitly present in eq. (38), while the unsubtracted eq. (37) is gauge invariant.

25 In the MC practice regularization of $1/(1 - z)$ is done with some cut-off $1 - z > \delta$ rather than with $\varepsilon$ of the dimensional regularization.

26 The last term in $\Delta_{V+S}$ is due to the plus-prescription in the $(1 - z)_+$ part of the MC counterterm of eq. (40).
term of eq. (40):

\[
f_{D\text{Y}}^{\text{MC}}(z) - f_{D\text{Y}}^{\text{LO}}(z) = -2K_F^{\text{MC}}(z, \varepsilon) + 2K_F^{\text{MS}}(z, \varepsilon)
\]

\[
= \frac{C_F \alpha_s}{\pi} (1 - z) + 2 \frac{C_F \alpha_s}{\pi} \left( \frac{\bar{P}(z)}{1 - z} + \frac{\ln \frac{\delta}{\mu^2} + \omega_2}{1 - z} \right)
\]

\[
+ \frac{C_F \alpha_s}{\pi} \left\{ 4 \bar{P}(z) \ln(1 - z) - 2 \bar{P}(z) \ln \frac{1}{1 - z} \right\} + \text{(45)}
\]

and it represents clearly the difference between the MS and the MC factorization schemes.

One may ask how to interpret this change from MS factorization scheme to MC factorization scheme, in particular, how unique the modified MC counterterms of eq. (40) are. One may answer this question in two complementary ways. One way is that the new MC counterterm of eq. (40) represents just the collinear limit of the exact matrix element in \( n = 4 + 2\varepsilon \) dimensions (keeping higher order terms in \( \varepsilon \) in a sense of the \( \mathbb{P}' \) projection operator. This definition has to be supplemented with the plus prescription in the soft limit or, alternatively, by saying that \( Z_F \), which in CFP (MS) provides for plus prescription, is replaced by the Sudakov form-factor. This approach represents an effort in combining the best from the two, the collinear and soft resummation. Another way of addressing this question is to say that the real backbone in the collinear factorization is OPE with CFP providing a solid bridge to OPE, and the only thing that has to be explained and kept track of is the difference between CFP and MC (in a similar way like finite UV renormalization). This approach was already advocated in refs. [4, 43] and in other papers [39], where factorization scheme dependence was discussed. In our approach, we are using both ways of addressing the above question.

The related question is whether the counterterm of eq. (40) is universal? Basically the answer is that it is universal thanks to the fact that it is defined in terms of the \( \tilde{k}' = \lambda k' \) variables. In other words, the kinematic mapping, inherent in the new \( \mathbb{P}' \) operator, should remove the hard process dependence on the side of the ladder, in the same way as the pole-part operation in CFP [26] or \( P_{\text{fin}} \) of ref. [4]. To be completely certain that the above aim of the universality of the new MC factorization scheme is achieved, in next section we shall define a similar MC scheme for the DIS process, define and use the collinear counterterm of this MC scheme, and in Sect. [V] we shall check validity of the factorization scheme independent relation (DY−2×DIS) of ref. [30] between the coefficient functions of DY and DIS, both taken in the MC factorization scheme.

F. Differences compared with POWHEG and MC@NLO methods

In this subsection we outline main differences of our method compare to the well established approaches of POWHEG [11] and MC@NLO [9] used today to combine NLO-corrected hard process with the LO parton shower.

First and most obvious difference between our method and those of POWHEG and MC@NLO is use of different factorization schemes. In our approach we use factorization scheme [16, 17] designed especially for MC simulations whereas POWHEG and MC@NLO use the standard MS scheme. This allows them to use directly the standard MS collinear PDFs, while we need additional work here [4, 43]. Moreover, we build the LO parton shower MC from scratch whereas POWHEG and MC@NLO profits from the well established (unmodified) LO MC programs.

At first it may seem that these general features result in unnecessary complications in our approach, however, profits are more important, especially if we have in mind construction of the fully NLO MC parton shower (with NLO corrections, not only in the hard process, but also in the ladder parts). Our method features:

(i) simple and positive MC weight implementing the NLO on top of the LO MC, see ref. [21] (MC@NLO features negative weights);

(ii) no need to correct for the difference in the collinear counterterm of the LO MC and the standard MS scheme;

(iii) the virtual+soft corrections \( \Delta V_{+S} \) are completely kinematics independent – all annoying \( d\Sigma_{+S} \) contributions of MC@NLO are gone;

(iv) built-in resummation of the \( \frac{\ln^k(1-x)}{1-x} \) terms is provided;

(v) direct relation to the collinear factorization procedures.

Note also that, in the presented method there is no need to define the hardest emission, as in POWHEG, as it is automatically included into the sum over spectator gluons in the formula for the MC weight in eq. (35). In fact, we can explicitly see that the dominant contribution is from the “hardest” (in \( k_T \)) gluon [27] for numerical illustration see ref. [21]. This allows us to avoid truncated/vetoed gluons needed in POWHEG methodology in case of angular ordering.

A detailed comparison of MC@NLO and POWHEG methods themselves can be found in refs. [44, 45].

IV. DEEP INELASTIC ELECTRON–PROTON SCATTERING

As already said, the process of deep inelastic electron–proton scattering (DIS) is included in the scope because it is is an important source of information on parton distributions in a proton and, by comparing the DIS and DY processes, the question of universality in the collinear factorization implemented in the MC can be fully discussed.

27 One possibility is refitting PDFs, which shouldn’t be too complicated as the difference between MC and MS scheme on the inclusive level is small.

28 This is just a relabeling according to \( k_T \), we do not need to change previously generated, angular-ordered gluons. It is only exploited here for the purpose of efficient evaluation of the NLO MC weight.
In the following subsections we shall first introduce kinematics, phase space and notation for one real gluon emission. Next, we shall define the multigluon LO MC distribution with initial-state radiation (ISR) and final-state radiation (FSR) LO ladders and the LO matrix element for the hard process for electron-hadron DIS. Analytical integration of the MC distribution will lead to the familiar formula for structure function $F_2$ in the form of the convolution of PDF with the Born cross section. Then we shall give a close simple formula for the MC weight implementing the NLO correction to the hard process. The analytical integration will be again possible giving the structure functions $F_2$ and $F_1$ in form of the convolution of PDF with the NLO coefficient function. Of course, the above NLO coefficient function will be in the MC factorization scheme, but we shall see that universality is preserved, by means of checking validity of the factorization scheme independent relation $D Y - 2 \times D I S$ of ref. [30] between the coefficient functions of the DY and DIS processes.

### A. One-real gluon distribution and kinematics

![Kinematics of one gluon emission in the Breit frame.](image)

The Born differential cross section of the electron-quark scattering $e(p_1) + q(q_1) \rightarrow e(p_2) + q(q_2)$ in terms of the standard variables $s = 2p_1q_1$, $t = 2p_1q_2$, $u = 2p_1q_2$ reads

$$d\sigma_B = \frac{Q_q^2}{s} \left( \frac{1}{s} \right) d\phi \frac{Q_q^2}{\pi} \frac{s^2 + u^2}{t^2},$$

where $Q_q$ is the quark charge. Next, consider the process with emission of an additional gluon from the quark line:

$$e(p_1) + q(q_1) \rightarrow e(p_2) + q(q_2) + g(k).$$

The differential distribution in this case reads

$$d\sigma_1 = \frac{Q_q^2}{s} \frac{Q_{ED}^2}{s} \left( \frac{1}{s} \right) d\phi \frac{Q_q^2}{\pi} \frac{s^2 + u^2 + w^2}{2t_1} d\psi \frac{2\pi}{2t_1}$$

The additional invariants $s_1 = 2p_2q_2$, $t_1 = 2q_1q_2$, and $\psi$ are introduced in this case. The factor $\frac{1}{t_1}$ is the Jacobian due to parametrization of the phase space in terms of the rescaled Sudakov variables [46, 47]:

$$\alpha = \frac{2kq_2}{t_1 + 2kq_1}, \quad \beta = \frac{2kq_1}{t_1 + 2kq_1}. \quad (48)$$

The angle $\psi$ is the azimuthal angle of $\vec{k}$ around $z$-axis in the Breit frame of $Q = q_2 + k - q_1$, that is where $Q^0 = 0$, with an additional requirement that $q_1$ is parallel to the $z$ axis. We call this the reference frame $B$, see Fig. 4.

Yet another Breit frame $B_1$ is marked in Fig. 4, that of $Q_1 = q_2 - q_1$ with the $z$-axis along $q_1$. It will be used in the MC and in the analytical calculations. Note that the integration is over the angle $\psi_1$ of the $k$, $q_1$, $q_2$ plane as a whole around $\vec{\Pi}$, while another azimuthal angle $\phi_1$ of $\vec{k}$ in the $B_1$ frame is frozen to zero. Note that the standard Sudakov variables are:

$$\alpha' = \frac{kq_2}{q_1q_2}, \quad \beta' = \frac{kq_1}{q_1q_2}, \quad t = t_1(1 - \alpha' + \beta'). \quad (49)$$

They are not convenient because $\beta' \in (0, \infty)$, and the following transformation is mandatory [30]:

$$\alpha = \frac{\alpha'}{1 + \beta'}, \quad \beta = \frac{\beta'}{1 + \beta'}, \quad \alpha' = \frac{\alpha}{1 - \beta'}, \quad \beta' = \frac{\beta}{1 - \beta},$$

$$0 < \alpha \leq 1 - \frac{t}{s}, \quad 0 < \beta \leq 1, \quad t_1 = t \frac{1 - \beta}{1 - \alpha}. \quad (50)$$

### B. Bjorken variables, structure functions, collinear limits

The standard Bjorken variables are

$$x_B \equiv \frac{t}{2q_1Q} = \frac{|Q^2|}{2q_1Q}, \quad 1 \geq x_B > 0, \quad y_B \equiv \frac{Qq_1}{p_1q_1} = \frac{t}{sx_B}. \quad (51)$$

In the case of a single gluon they are expressed as follows

$$x_B = \frac{t}{2q_1Q} = 1 - \alpha' + \beta', \quad y_B = \frac{2q_1Q}{2q_1p_1} = \frac{t}{sx_B}. \quad (52)$$

The reader should keep in mind that for simplicity $x_B$ is the fraction of the parton momentum in the initial quark [31].

---

29 We omit the minus sign in the variables like $t$ and $u$ with respect to the standard notation.

30 In the collinear limit $k \approx q \beta/(1 - \beta)$, with $\varepsilon = 1 - \beta$ being the lightcone variable in the LO splitting kernel.

31 Returning to the normal definition in the MC (a fraction of the hadron momentum) is quite trivial.
Let us recall the definitions of the standard deep-inelastic structure functions in terms of the above Bjorken variables:

$$\frac{d^2 \sigma}{dtdx_B} = \frac{2\pi\alpha_s^2}{t^2} \int x_B^{-1} \left\{ \frac{2}{y_B^2} 2x_B F_1(x_B) + 2(1-y_B)F_2(x_B) \right\},$$

$$= \frac{2\pi\alpha_s^2}{t^2} \int x_B^{-1} \left\{ \left[ 1 + (1-y_B)^2 \right] F_2(x_B) - y_B^2 x_B F_L(x_B) \right\},$$

$$= \frac{2\pi\alpha_s^2}{t^2} \int x_B^{-1} \left\{ \left[ 1 + (1-y_B)^2 \right] 2x_B F_1(x_B) + 2(1-y_B) x_B F_L(x_B) \right\},$$

(53)

where we have employed the standard definition $2x_F \equiv F_2 - x F_L$. In the LO case the Callan-Gross relation $2x_F = F_2$ is fulfilled and the longitudinal structure function $F_L = 0$ (it will receive a nonzero contribution at NLO). The LO relation to the parton distribution function (luminosity) is $2F_1(x) = F_2/x = \text{PDF}(x)$.

It is instructive to investigate the collinear ISR and FSR limits. The slightly reorganized single-gluon emission distribution reads

$$d\sigma_1 = \alpha_s^2 Q^2 \frac{dt}{t^2} d\psi \frac{d\alpha}{\alpha} \frac{d\beta}{\beta} W,$$

$$W = \frac{s^2 + u_t^2 + u_s^2 + u_B}{2s^2}.$$  

(54)

The soft limit is already manifest in the eikonal phase space factor $\frac{d\alpha d\beta}{\alpha \beta}$. The following explicit expressions for the invariants in terms of our Sudakov variables are useful:

$$\frac{t_1}{s} = (1-\beta)y_B, \quad \frac{u_t}{s} = 1-y_B, \quad \frac{u_B}{s} = \frac{s_1}{s} = (1-\alpha)(1-\beta) + \alpha \beta (1-\beta),$$

$$s_1 \simeq (1-\alpha)(1-\beta) - \alpha \beta (1-\beta) + 2\cos \psi \sqrt{(1-\alpha)(1-\beta) \alpha \beta (1-y_B)).$$

(55)

In the FSR collinear limit, $\alpha \simeq 0, \beta \simeq 1-z, k \simeq q_2(z) \alpha S_2$ and $y_B \simeq y_0 = t/s$, we have

$$s^2 + u_t^2 \simeq s^2 + (s-t)^2, \quad s_1^2 + u_B^2 \simeq (s^2 + (s-t)^2)(1-\beta)^2,$$

$$W \simeq \frac{1}{2} \frac{1+(1-\beta)^2 s^2 + (s-t)^2}{s^2} \frac{1 + z^2}{2} [1 + (1-y_B)^2].$$

(56)

In the ISR collinear limit $\beta \simeq 0, \alpha \simeq 1-z$ and $k \simeq (1-z) q_1$ we have:

$$s^2 + u_t^2 \simeq s^2 + \left( s - \frac{t}{1-\alpha} \right)^2,$$

$$s_1^2 + u_B^2 \simeq [s(1-\alpha)]^2 + [s(1-\alpha) - t]^2,$$

$$W \simeq \frac{1 + (1-\alpha)^2}{2} \frac{1 + (1-y_B)^2}{2} [1 + (1-y_B)^2].$$

(57)

C. Bare structure functions for 1-gluon emission

Our immediate aim is now to reproduce the well known \[26, 48, 49\] result for the NLO correction to the $F_2(x)$ structure function by means of integration of the one-gluon phase space (the NLO correction to $F_L(x)$ will also be found). The aim is to test our Monte Carlo phase space parametrization, prepare ground for determining the soft+virtual correction in the MC and put FSR under control.

The unsubtracted (bare) contribution to $F_2(x)/x$ corrected due to the real gluon emissions plus the vertex correction (eq. (59) in \[30\]) can be rewritten as:

$$C^{\text{bare}}_{2,\text{bare}}(x) = \delta(1-z) + \frac{C_F \alpha_s}{\pi} \left\{ P_{qq}(z) \left[ \frac{1}{\epsilon} + \omega_2 \right] + P_{\gamma q}(z) \ln \frac{t(1-z)}{zq^2} \frac{3}{4} \frac{1}{1-z} + \frac{1}{2} (3+2z) \right\} + \epsilon,$$

(58)

where $P_{qq}(z) = \frac{1+z^2}{2(1-z)}, \omega_2 = \gamma_E - \ln(4\pi)$ comes from the $\Omega_{2-z} = 2\pi(1+\epsilon \omega_2 + \ldots)$ expansion. The baryon number conservation sum rule $\int_0^1 dz C^{\text{bare}}_{2,\text{bare}}(z) = 1$ holds explicitly.

The standard NLO MS correction $C_2$ to $z^{-1} F_2(z)$ form-factor is obtained simply by means of subtracting the MS collinear counterterm $\frac{1}{2} \{ P_{qq}(z) \}$, (i.e. the pole part). The formula of ref. \[48\] to be reproduced reads:

$$\Delta F_2^{\text{NLO}}(x_B) = C_2(x_B) =$$

$$= \frac{C_F \alpha_s}{\pi} \left\{ P_{qq}(x_B) \left[ \ln \frac{t(1-x_B)}{\mu^2 x_B} + \omega_2 \right] - \frac{3}{4} \frac{1}{1-x_B} + \frac{3}{2} + x_B \right\} +$$

$$= \frac{C_F \alpha_s}{\pi} \left\{ P_{qq}(x_B) \left[ \ln \frac{t(1-x_B)}{\mu^2 x_B} + \omega_2 \right] - \frac{3}{4} \frac{1}{1-x_B} + 1 + \frac{3}{2} x_B \right\} +$$

$$+ \frac{C_F \alpha_s}{\pi} \left\{ \frac{1 - x_B}{2} \right\} + \epsilon.$$  

(59)

The last term $(1-x_B)/2$ in the non-singular part is due to the $\epsilon$-term from the $\gamma$-trace for the intitial-state collinear singularity and $\omega_2$ from the $n$-dimensional phase space.

We start from the unsubtracted (bare) DIS distribution coming from two real-gluon emission diagrams from the quark line plus the vertex correction in $n = 4 + 2\epsilon$ dimen-

---

32 We subtract a pure pole as in the original CFP work and not $(\frac{1}{\epsilon} + \omega_2) \{ P_{qq}(z) \}$, as it is a common practice nowadays.
we may omit the details of its calculation. The complicated phase space factor is simply due to the fact that the transverse momentum of the gluon in the Breit frame is:

\[ k_T^2 = |\mathbf{k}|^2 = t_1 \alpha' \beta' = \frac{t \alpha \beta}{(1 - \alpha)(1 - \beta)}. \]

Finally, \( \int d\Omega^y_{2+2k} \) is the \( n \)-dimensional extension of \( \int_0^{2\pi} d\psi \).

In the CFP scheme the ISR collinear singularity upon integration gives rise to the LO pole part

\[ C_0^{[0]} P K_{0f} = C_0^{[0]} T_{1}^{[1]}(x_B) = \frac{1}{\xi} \left[ 1 + (1 - y_B)^2 \right] \frac{C_F \alpha_s}{\pi} \left( \frac{P(x_B)}{1 - x_B} \right)_+, \]

where \( K_{0f} \) is the lowest-order 2PI kernel for the ISR ladder and the \( + \) prescription comes from \( Z_F \), as usual. The subtracted hard process matrix element in the CFP scheme is \( C_0^{[1]} - C_0^{[0]} P K_{0f} \). We shall calculate it with the help of the usual counterterm technique. The ISR collinear/soft counterterm (SCT) we define as follows:

\[
\rho_{yz}(\alpha, \beta) = \left[ 1 + (1 - y_B)^2 \right] \frac{C_F \alpha_s}{\pi} \frac{P(1 - \alpha)}{\alpha} \times \beta^{-1} B^{-\xi} \theta_{\beta < B(\alpha)} \theta_1 > \alpha > \delta, \tag{61}
\]

\[ B(\alpha) = \frac{\mu^2 (1 - \alpha)}{\alpha}. \]

It is defined such that it integrates to the pure pole part exactly:

\[ C_0^{[0]} T_{1}^{[1]}(x_B) = \int d\alpha d\beta \rho_{yz}(\alpha, \beta) \delta_{1 - x_B = \alpha}. \]

In Fig.[5] we have also marked the integration area for the above counterterm. As we see, in this area the upper phase space integration limit from the energy momentum conservation is replaced by the limit on the gluon transverse momentum (approximately) to \( \mu \).

With the help of the above ISR collinear counterterm our task is reduced to calculate the subtracted DIS distribution in \( n = 4 \) dimensions:

\[ G_2(x_B, y_B) = \int d\alpha d\beta \int_0^{2\pi} \frac{d\psi}{2\pi} \left[ \rho_2(\alpha, \beta) - \rho_2(\alpha, \beta) \right] \delta_{x_B = 1 - \alpha}, \tag{62}\]

except for the trivial \( \varepsilon \) term in \( W \), which contributes \( \frac{C_F \alpha_s}{\pi} \left( \frac{1 - x_B}{2} \right)_{+} \), to be added at the end. The same with the similar \( \varepsilon \omega \) term from the phase space.

The integration can be summarized as follows:

---

33 Only for the ISR collinear singularity; the one for FSR falls into the \( U \) factor.
\[ \frac{d^2 \sigma_{\text{LO}}}{dt dx_B} = \frac{2 \pi \alpha_s^2 Q_2^2}{t^2} \frac{2 C_F \alpha_s}{\pi^2} \int d^{3}E(k_1) \left[ W(\alpha, \beta, y_B) - W_0(y_B) \hat{P}(1-\alpha) \theta_{\beta_1<\beta_1} \right] \delta_{t-x_B = 1} \]
\[ = \frac{2 \pi \alpha_s^2 Q_2^2}{t^2} (1 + (1-y_B)^2) C_L^2(x_B) - y_B^3 C_L(x_B), \]
\[ C_L^2(x_B) = C_F \frac{2}{\pi} \left\{ P_{qq}(x_B) \ln \left( \frac{1-x_B}{x_B} \right) - \frac{3}{4} \left( \frac{1}{2x_B} + 1 - \frac{3}{2} x_B \right) \right\} + \frac{C_F \alpha_s}{\pi} \left\{ \frac{1-x_B}{2} \right\}, \]
\[ C_L(x_B) = C_F \frac{\alpha_s}{\pi} x_B, \quad W_0(y) = 1 + (1-y)^2, \]

where the + prescription is provided by the virtual corrections. We have also included the e-contribution from the γ-trace and ω_2 from the phase space. As we see, C_L^2(z) is equal to the finite part of \( C_{2\text{EM}}^\text{inv}(z) \) of eq. (58), thus we have reproduced the classic result [48], as promised.

In the MC scheme the ISR counterterm \( C_0^{(0)} \| p' K_0 \| \) is defined as the single-gluon distribution which is extrapolated to \( n = 4 + 2 \varepsilon \) dimensions and integrated over the phase space:

\[ K_I(z, \varepsilon) = \frac{C_F \alpha_s}{\pi} \int \frac{d\alpha d\beta}{\alpha \beta} \int d\Omega_{2+2\varepsilon} \left( \frac{r \alpha \beta}{1-\alpha \beta} \right)^{\varepsilon} \times \hat{P}(1-\alpha, \varepsilon) \theta_{\beta_1<\beta_1} \theta_{\varepsilon<\beta_1} \delta(1-z) S_I \]
\[ = \frac{C_F \alpha_s}{\pi} \left( \frac{t}{2 \pi r^2} \right)^{\varepsilon} \Omega_{2+2\varepsilon} \frac{P(z, \varepsilon)}{\varepsilon} \left( \frac{1}{1-z} \right)^{1-2\varepsilon} \theta_{1^{-}\varepsilon} \delta(1-z) S_I \]
\[ = \frac{C_F \alpha_s}{\pi} \left( \frac{\hat{P}(z, \varepsilon)}{1-z} \right) \left[ \frac{1}{\varepsilon} + \frac{\ln t}{2 \pi r^2} \right], \]
\[ S_I = \frac{C_F \alpha_s}{\pi} \Omega_{2+2\varepsilon} \frac{1}{\varepsilon} \int_0^{1-2\varepsilon} dz \left( \frac{\hat{P}(z, \varepsilon)}{1-z} \right)^{\varepsilon} \left( \frac{t}{2 \pi r^2} \right), \]

where \( \hat{P}(z, \varepsilon) = \hat{P}(z) (1 + 2 \varepsilon \ln (1-z)) + \frac{\varepsilon}{2} (1-z)^2 \). The source of the + prescription in this case is the MC Sudakov form-factor calculated in \( n = 4 + 2 \varepsilon \) in such a way that the sum rule \( \int dt K_I(z, \varepsilon) = 0 \) is preserved also in \( n \)-dimensions:

\[ \int d\Omega_{2+2\varepsilon} \hat{P}(z, \varepsilon) \left( \frac{1}{1-z} \right)^{1-2\varepsilon} \left( \frac{t}{2 \pi r^2} \right)^{\varepsilon} = 1, \]

from the different cut-off in the ISR counterterms:

\[ \frac{2 \pi \alpha_s^2 Q_2^2}{t^2} \frac{C_F \alpha_s}{\pi} \int d^{3}E(k_1) W_0(y_B) \times \left[ -\hat{P}(1-\alpha) \theta_{\beta_1<\beta_1} \right] \delta_{t-x_B = 1} \]
\[ = \frac{2 \pi \alpha_s^2 Q_2^2}{t^2} W_0(y_B) \frac{C_F \alpha_s}{\pi} \left( 2 P_{qq}(x_B) \ln(1-x_B) + P_{qq}(x_B) \ln \frac{t}{\mu^2 x_B} \right). \]

A few comments are in order:

- **Why not \( k^- \)-ordering?** In such a DIS-like factorization scheme [34], term \( \left[ \frac{\ln(1-x)}{1-x} \right] \) would have been gone from eq. (65). FSR could be treated in the DIS MC without the LO resummation, with the unexponentiated FSR NLO corrections. However, if the universality is to be maintained, and the same \( k^- \)-ordering is applied to the W/Z production process, that would either mean asymmetric treatment of the emission from the quark and antiquark lines or a large double logarithmic dead zone in the corresponding LO MC, between the ISR and FSR phase spaces. Both options are unacceptable.

- **Is there also a kinematic mapping involved in the above \( p' \), like in the previous W/Z production process?** Yes, it is implicitly included in the definition of \( \alpha \) and \( \beta \) variables in eq. (59), where dilatation using factor \( 1/(1+\beta') \) factor is seen.

- **From the point of view of the MC the above considerations are incomplete, as they still keep FSR in the inclusive/integrated form.**

### D. DIS multigluon LO Monte Carlo

Let us start with the raw distribution for \( n \) gluons, the \( (\alpha C_F)^n \) part only, relevant for the LO MC.

\[ e(p_1) + g(q_1) \rightarrow e(p_2) + g(q_2) + g(k_1) + g(k_2) + \ldots + g(k_n). \]
The corresponding differential distribution reads
\[ \sigma_n = \frac{Q^2 \alpha_s^2 \sqrt{d \phi}}{\pi} \int_{t_1}^{W} \frac{d\psi}{2\pi} \left( \frac{C_F \alpha_s}{\pi} \right)^n \times \left( \prod_{i=1}^{n} \frac{d\alpha_i d\beta_i}{\alpha_i \beta_i} \right) \delta_s \left( \sum_j \beta_j \right) \]  
where \( W \) is a mild function to be defined later on. The invariants \( s_1 = 2p_2 q_2, u_1 = 2q_1 p_2, t_1 = 2q_1 q_2 \) are the same as previously. The factor \( \frac{1}{t} \) is again the Jacobian due to the parametrization of the phase space in terms of the Sudakov variables \([50]\), see below. The angle \( \psi \) is the azimuthal angle of \( \vec{k} \) around the \( z \)-axis in the Breit frame of \( \vec{Q} = q_2 + k - q_1 \) with \( Q_0 = 0 \), with the additional requirement that \( \vec{q}_1 \) is parallel to the \( z \)-axis. We call this reference frame \( B \). Another Breit frame \( B_1 \) is used in the MC, that of \( Q_1 = q_2 - q_1 \) with \( z \)-axis also along \( \vec{q}_1 \) (and \( \vec{q}_2 \)). The illustration of the kinematics in Fig. 4 is still valid, provided we replace \( k_j \) by \( \sum j k_j \).

The integration is done over the angle \( \psi \) of the (\( \Pi, q_1, q_2 \)) plane as a whole around \( \Pi = \vec{q}_2 + \sum j k_j \), while there is a single restriction on \( n \) azimuthal angles \( \phi_i \) of \( k_j \) in the \( B_1 \) frame, namely the vector \( \sum j k_j \) must be co-planar with \( p_1 \) and \( p_2 \).

The standard Sudakov variables are:
\[ \alpha'_i = \frac{k_i q_2}{q_1 q_2}, \quad \beta'_i = \frac{k_i q_1}{q_1 q_2}, \quad t = \frac{1}{t_1} \left( 1 - \sum_j \alpha'_j + \sum_j \beta'_j \right) - K^2, \quad K = \sum j k_j. \]  

Next, we transform them as follows \([50]\):
\[ \alpha_i = \frac{\alpha'_i}{1 + \sum_j \beta'_j}, \quad \beta_i = \frac{\beta'_i}{1 + \sum_j \beta'_j}, \quad \alpha'_i = \frac{\alpha_i}{1 - \sum_j \beta_j}, \quad \beta'_i = \frac{\beta_i}{1 - \sum_j \beta_j}, \quad 0 < \sum_j \alpha_j \leq 1 - \frac{t}{s}, \quad 0 < \sum_j \beta_j \leq 1. \]  

The Bjorken variable \( x_B \) (of parton in the initial quark) can be expressed in terms of the Sudakov variables. Using \( Q = K + q_2 - q_1 \) and \( K = \sum j k_j \), we obtain
\[ x_B = \frac{2q_1 q_2 + 2q_2 K - K^2}{2q_1 q_2 + 2q_1 K} = \frac{1 + \sum_j \beta'_j - \sum_j \alpha'_j}{1 + \sum_j \beta'_j} - K^2 \]
\[ = 1 - \sum_j \alpha_j - K^2 = \frac{t}{t_1 (1 + \sum_j \beta'_j)}. \]  

In the NLO world the term
\[ K^2 = \frac{K^2}{2q_1 Q} = \frac{2 \sum_{i>j} k_i k_j}{2q_1 Q} \]
can be either omitted or taken care of in the collinear limit. Note that \( K^2 \) is absent in the case of the single-gluon calculation of the NLO coefficient function.

The fully differential distribution for emitting \( n \) gluons in the LO MC for DIS we define as follows:
\[ \sigma_n = \frac{Q^2 \alpha_s^2 \sqrt{d \phi}}{\pi} \frac{1}{t^2} e^{S} \frac{d\psi}{2\pi} \delta_s \left( \sum_j \beta_j \right) \prod_{i=1}^{n} \frac{C_F \alpha_s}{\pi} \frac{d\alpha_i d\beta_i}{\alpha_i \beta_i} \phi_i \left( \beta_i > \alpha_i \right) \]  

The key objects to be defined are the variables \( \xi_j \) and the Sudakov form-factor \( S \). For this LO modeling of the gluon-strahlung we use ordering according to the factorization scale (evolution) variable
\[ \xi_j = t \frac{\beta_j}{\alpha_j} \in \left( \Delta, \frac{t}{\Lambda} \right), \]
which is the variable of the angular ordering of the MC.

The ISR part of the Sudakov plane (the blue trapezoid in Fig. 6) contains the gluons \( I = \{1, 2, 3, ..., m\} \) which have \( \beta_j / \alpha_j < e^\xi \) and the FSR part (the red trapezoid in Fig. 6) hosts the gluons \( F = \{m + 1, m + 2, ..., n\} \) which have \( \beta_j / \alpha_j > e^\xi \). We shall indicate that the gluon \( j \) belongs to one of these two subsets by \( j \in I \) or \( j \in F \). The variable \( \xi_j \) of the ISR and FSR gluon is defined in terms of either \( \alpha_j 's \) or \( \beta_j 's \):

for \( j \in I \): \[ \xi_j = \xi_j^I = \frac{x^I_j}{x^I_{j-1}}, \quad x^I_j = 1 - \sum \alpha_i, \]

for \( j \in F \): \[ \xi_j = \xi_j^F = \frac{x^F_j}{x^F_{j-1}}, \quad x^F_j = 1 - \sum \beta_i. \]  

The Sudakov form-factor \( S \) is the integral over the area in the logarithmic Sudakov plane available for the real emission in the step-by-step Markovian process. This area is visualized in Fig. 5 as a shaded polygon. The rapidity \( \Xi \) defines the boundary between the ISR and FSR emissions according to the corresponding LO distribution and can be treated as an arbitrary parameter, for example \( \Xi = 0 \) in Fig. 5b is an acceptable LO choice. In fact, another more clever choice of \( \Xi \), like the one indicated in Fig. 5c, can be made, for instance, within the Markovian LO MC algorithm. It is also possible to switch from one value of \( \Xi \) to another in the final stage of the LO MC by means of reweighting MC events. In view of the above flexibility, we leave out the exact definition of \( \Xi \) to the later stage of the MC code implementation.

### E. Structure function for LO MC

The standard double-differential distribution of the DIS process, as realized in our LO MC, is obtained by inserting...
FIG. 6. The Sudakov plane of the LO MC for DIS. The shaded area denotes the integration domain for the Sudakov form-factor $S$ of the LO MC. Rapidity equal to $\Xi$ marks the boundary between ISR and FSR.

The above distribution is directly implementable in the MC form, for instance using the Markovian algorithm, and the above double differential distribution of $x_B$ and $t$ is coming just from histogramming, using MC events with all 4-momenta of all leptons, quarks and gluons explicitly defined.

On the other hand, we may explicitly show analytically that the above distribution is proportional to PDF convoluted with the coefficient function. This is done by means of inserting into the integrand $1 = \prod_{i=1}^{n} (\theta_{a_i > a_2} + \theta_{a_i < a_2})$ and after expanding/reordering the sums of the integrals. The distribution of eq. (74) almost factorizes into the ISR and FSR parts:

$$\frac{d^2\sigma^{d\ell}}{dt dx_B} = \frac{2\pi Q^2_a \alpha_s^{2qED} \!}{t^2} W_0(y_B) \left[ \sum_{n=0}^\infty \left( \prod_{i=1}^{n} \frac{2C_F \alpha_s}{\pi^2} \int d^3E(k_i) \bar{P}(z_i^F) \theta_{a_i > a_2} \right) e^{-S_t} \right]$$

where we have split the Sudakov form-factor into the ISR and FSR parts, $S = S_t + S_F$ and $\beta_t = \sum_{i} \beta_{iF}$. In the above we have also neglected $K^2$ in $x_B = 1 - \sum_j \alpha_j - K^2$. This is well justified at LO, but it turns out that it can be done at NLO as well. The alternative solution would be to make special effort in parametrizing the phase space (part of the definition of the $P'$ operator) to "protect" $x_B$ as it was done for $\hat{x} = \hat{s}/s$ in the $W/Z$ production process. We have decided that this is not worth the effort, as the dependence on $x_B$ of the differential distributions is relatively mild. We may come back to this idea if an additional justification is found.

Altogether, the final LO formula can be written as a convolution of the PDF for ISR and the the resummed "coefficient function" $C_F(z_F)$ for FSR:
The interesting pure FSR object $C^F(x)$ is probing the FSR evolution variable, instead of the LO lightcone variable! In the LO version it is enough to keep only the trivial $C^F(x) = \delta(1-x)$ term, while for our NLO purpose it is enough to retain only one more easily calculable term, $n' = 1$, $\Xi = 0$:

$$C^{(1)}_F(x) = \delta(1-x) + \frac{C_F a_s}{\pi} \left( \int_0^1 \left[ \int_0^1 \frac{d\alpha_1 d\beta_1}{\alpha_1 \beta_1} \tilde{P}(1-\beta_1) \delta_{\alpha_1 < \beta_1} \delta_{1-x - \alpha_1} \right] + \int_0^1 \left[ \int_0^1 \frac{d\alpha_1 d\beta_1}{\alpha_1 \beta_1} \tilde{P}(1-\beta_1) \delta_{\alpha_1 < \beta_1} \delta_{1-x - \alpha_1} \right] + \int_0^1 \left[ \int_0^1 \frac{d\alpha_1 d\beta_1}{\alpha_1 \beta_1} \tilde{P}(1-\beta_1) \delta_{\alpha_1 < \beta_1} \delta_{1-x - \alpha_1} \right] ight).$$

(77)

NB. the above reproduces the bulk of the coefficient function of eq. (65), that is terms like $\left( \int \frac{1}{1-x} \right)_+$ and $\left( \int \frac{1}{1-x} \right)_-$. The MC initial–state PDF obeys the LO DGLAP evolution equation (limited to the non-singlet gluonstrahlung):

$$2t \frac{\partial}{\partial t} D_I(t,x) = \frac{\partial}{\partial x} D_I(t,x)$$

$$= \int dz dx \delta_{x = z} \frac{C_F a_s}{\pi} \left( \frac{\tilde{P}(z)}{1-z} \right) + D_I(t,x),$$

(78)

and the same is true for the structure function 2$F_1 = C^F \otimes D_I$:

$$2t \frac{\partial}{\partial t} F_I(t,x) = \frac{\partial}{\partial x} F_I(t,x)$$

$$= \int dz dx \delta_{x = z} \frac{C_F a_s}{\pi} \left( \frac{\tilde{P}(z)}{1-z} \right) + F_I(t,x).$$

(79)

### F. Exclusive ISR and FSR subtractions in DIS

The two soft counterterms, for ISR and FSR, can be identified in the fully differential distribution of the single-real gluon in the LO MC:

$$d\sigma^{MCLO}_1 = Q^2 y^2 \frac{d^2 \alpha}{dz dx} \frac{d\Omega^2_{QED \Delta t \Delta \phi}}{2 \pi} = \frac{d\psi}{2 \pi} \delta_y \frac{1}{t^2} W_0(y) \int d\psi \delta_y \frac{1}{t^2} \frac{d\alpha_1 d\beta_1}{\alpha_1 \beta_1} \frac{d\theta_1}{2 \pi} \left( \tilde{P}(1-\alpha_1) \delta_{\beta_1 < \alpha_1} + \tilde{P}(1-\beta_1) \delta_{\alpha_1 < \beta_1} \right),$$

(80)

where we define the $y_B = \frac{t_{1/2} - \alpha_1}{t_{1/2} - \beta_1}$ variable and the Born spin factor is $W_0(y) = 1 + (1-y)^2$. On the other hand, the NLO-complete unsubtracted distribution is

$$d\sigma^{NLO}_1 = Q^2 y^2 \frac{d\alpha_1}{dz dx} \frac{d\Omega^2_{QED \Delta t \Delta \phi}}{2 \pi} = \frac{d\psi}{2 \pi} \delta_y \frac{1}{t^2} \left[ C_F a_s \frac{d\alpha_1 d\beta_1}{\alpha_1 \beta_1} \frac{d\theta_1}{2 \pi} \left( \tilde{P}(1-\alpha_1) \delta_{\beta_1 < \alpha_1} + \tilde{P}(1-\beta_1) \delta_{\alpha_1 < \beta_1} \right) + C_F a_s \frac{d\alpha_1 d\beta_1}{\alpha_1 \beta_1} \frac{d\theta_1}{2 \pi} \left( \tilde{P}(1-\alpha_1) \delta_{\alpha_1 < \beta_1} + \tilde{P}(1-\beta_1) \delta_{\beta_1 < \alpha_1} \right) \right].$$

(81)

See eq. (53) for explicit Mandelstam invariants.

For the MC we shall use the subtracted distribution with both the ISR and FSR counterterms:

$$d\sigma^{NLO}_1 = d\sigma^{NLO}_1 - d\sigma^{MCLO}_1 =$$

$$= Q^2 y^2 \frac{d\alpha_1}{dz dx} \frac{d\Omega^2_{QED \Delta t \Delta \phi}}{2 \pi} \left[ C_F a_s \frac{d\alpha_1 d\beta_1}{\alpha_1 \beta_1} \frac{d\theta_1}{2 \pi} \left( \tilde{P}(1-\alpha_1) \delta_{\beta_1 < \alpha_1} + \tilde{P}(1-\beta_1) \delta_{\alpha_1 < \beta_1} \right) + C_F a_s \frac{d\alpha_1 d\beta_1}{\alpha_1 \beta_1} \frac{d\theta_1}{2 \pi} \left( \tilde{P}(1-\alpha_1) \delta_{\alpha_1 < \beta_1} + \tilde{P}(1-\beta_1) \delta_{\beta_1 < \alpha_1} \right) \right],$$

(82)

which defines (up to NLO) the following expression

$$\tilde{C}^{NLO}_1(z, y_B / z) = C_F a_s \left[ \int_0^1 \int_0^1 \frac{d\alpha_1 d\beta_1}{\alpha_1 \beta_1} \frac{d\theta_1}{2 \pi} \left( \tilde{P}(1-\alpha_1) \delta_{\beta_1 < \alpha_1} + \tilde{P}(1-\beta_1) \delta_{\alpha_1 < \beta_1} \right) v_{1-z} v_{1-z} \right],$$

(83)

to be used in the numerical tests of the MC implementations.

### G. Exclusive NLO correction to hard process in DIS MC

In the following we propose a MC weight which upgrades the MC with the LO hard process and the LO evolution kernels to the MC with the NLO hard process and the LO evolution kernels.
kernels. The distribution in the LO+NLO MC reads

\[ d\sigma_{\text{NLO}}^n = Q_f^2 \alpha_s^2 \frac{dI}{dt} \frac{dW_f}{2\pi} \delta_1 \left( \sum_i \zeta_i \right) \times \left( \prod_{i=1}^n \frac{c_i \alpha_s}{\alpha_t \alpha_s} \frac{d\theta_i}{2\pi} P(z_i) \theta_{\alpha_t > \alpha_s} \right) \]

\[ \times \theta_{\alpha_t < 1} \theta_{\beta_{\alpha_s} < 1} e^{-S} W_0(y\beta) \ w_{\text{MC}}^{\text{ANLO}}, \tag{84} \]

where the key element is the following MC weight

\[ w_{\text{MC}}^{\text{ANLO}} = [1 + \Delta_{S+V}] + \sum_{j \in T} \tilde{\beta}_1(\alpha_j', \beta_j', y\beta) \sum_{j \in T} \tilde{\beta}_1(\alpha_j', \beta_j', y\beta) \]

\[ \times \frac{\tilde{\beta}_1(\alpha_j', \beta_j', y\beta)}{W_0(y\beta) P(z_j)} + \frac{\tilde{\beta}_1(\alpha_j', \beta_j', y\beta)}{W_0(y\beta) P(z_j)} \]

\[ = [1 + \Delta_{S+V}] + \sum_{j \in T} \tilde{\beta}_1(\alpha_j', \beta_j', y\beta) \sum_{j \in T} \tilde{\beta}_1(\alpha_j', \beta_j', y\beta) \]

\[ \times \frac{\tilde{\beta}_1(\alpha_j', \beta_j', y\beta)}{W_0(y\beta) P(z_j)} + \frac{\tilde{\beta}_1(\alpha_j', \beta_j', y\beta)}{W_0(y\beta) P(z_j)} \] \tag{85}

which adds the missing NLO correction of the real emission type and also includes \( \Delta_{S+V} \), representing the remaining NLO virtual+soft corrections.

The plus prescription for \( C^{(1)}_y(z) \) is provided by the Sudakov form-factor of the MC. \( \tilde{C}_F(z, y\beta) \) and \( \tilde{C}_F(z, y\beta) \) are completely finite/regular, without any \((...)_+\) parts. The IR regulator \( \delta \) will drop out at the end.

Let us now find out \( \Delta_{S+V} \) of the MC by means of comparing/matching the 1st order eq. (86) and/or eq. (85) with eq. (88) truncated also to the 1st order. Going back for a moment to \( n = 4 + 2\varepsilon \) we find out that the 1st order bare PDF of the LO MC is

\[ D_1(t,x_j)_{1st. ord.} = \delta(1-x_j) + K_1(x_j, \varepsilon), \quad \int_0^1 dz K_1(z, \varepsilon) = 0. \]

Also, as anticipated, the contribution \( C^{(1)}_y(z) \) cancels the counterterm in \( \tilde{C}_F(z, y\beta) \)

\[ W_0(y\beta) C^{(1)}_y(z) + \tilde{C}_F(z, y\beta) = D_1(z, y\beta, \delta) \]

\[ - W_0(y\beta) S_F(\delta) \delta(1-z), \tag{89} \]

\[ \tilde{D}_F(z, y\beta, \delta) = \frac{2C_F \alpha_s}{\pi^2} \int d^3 E(k) \frac{1}{2\pi^2} P(z_j) \theta_{\beta < \alpha} \delta(1-z), \]

\[ \times W(\alpha, \beta, y\beta) \theta_{\beta > \alpha}. \]
 Altogether the 1st order truncation of eq. (86) reads

\[
\frac{d^2\sigma^\text{NLO}_{\text{MC}(1)}}{dt dx_B} = \frac{2\pi Q^2 d_\text{QED}^2}{t^2} \left\{ \delta_{1=\gamma}\zeta_0(y_B)[1 + \Delta_{S+V} - S_F(\delta)] + W_0(y_B)K_{I}(x_B, \varepsilon) + \tilde{C}_I(x_B, y_B) + \tilde{D}_F(x_B, y_B, \delta) \right\},
\]

\[
\tilde{C}_I(z, y_B) + \tilde{D}_F(z, y_B, \delta) = \frac{2C_F \alpha_s}{\pi^2} \int d^2E(k) \times \{ W(\alpha, \beta, y_B) - W_0(y_B)\hat{P}(1-\alpha)\theta_1<\alpha_1 \} \delta_{1-\alpha} \theta_{1-\varepsilon} \]  

\[
= [W_0(y_B)\theta_1<\varepsilon] C^\prime_2(z) - y_B^2 C_L(z),
\]

(90)

where

\[
C^\prime_2(z) = \frac{C_F \alpha_s}{\pi} \left\{ \frac{1 + z^2}{2(1-z)} \ln \frac{1}{1-z} - \frac{3}{4} \frac{1}{1-z} + 1 + \frac{3}{2} \right\}.
\]

(91)

Remembering that (cf. eq. (65))

\[
C^\prime_2(z) = (C^\prime_2(z))_B + [\theta_{1-\varepsilon}] C^\prime_2(z) - \varepsilon T(\delta),
\]

\[
T(\delta) = \int_{0}^{1-\delta} dx C^\prime_2(x),
\]

we finally get

\[
\frac{d^2\sigma^\text{NLO}_{\text{MC}(1)}}{dt dx_B} = \frac{2\pi Q^2 d_\text{QED}^2}{t^2} \times \left\{ \delta_{1=\gamma}\zeta_0(y_B)[1 + \Delta_{S+V} - S_F(\delta) + T(\delta)] + W_0(y_B)K_{I}(x_B, \varepsilon) + \tilde{C}_I(x_B, y_B) + \tilde{D}_F(x_B, y_B, \delta) \right\}.
\]

(92)

Comparing with the NLO-complete (real+virtual) calculation (eg. eq. (63)), we see that the matching with the above MC implementation dictates the following relation (the Adler sum rule for F2):

\[
\Delta_{S+V} = S_F(\delta) - T(\delta) = \int_{0}^{1} dz [C^\prime_2(z) - C^\prime_2(\varepsilon)].
\]

(93)

The above formula is “ready to go” for numerical comparison with the Monte Carlo.

The virtual+soft correction \(\Delta_{S+V}\) is given by eq. (93), more precisely

\[
\Delta_{S+V} = \frac{C_F \alpha_s}{\pi} \int_{0}^{1} dz \left\{ - \frac{\ln(1-z)}{1-z} - \frac{3}{4} \frac{1}{1-z} + \frac{3}{4} + \frac{1}{4} \right\} + \frac{1 + z^2}{2(1-z)} \ln(1-z) + \frac{3}{4} \frac{1}{1-z} - \frac{1}{2} \right\} = \frac{C_F \alpha_s}{\pi} \int_{0}^{1} dz \left\{ - \frac{1 + z^2}{2} \ln(1-z) - \frac{1}{4} \frac{5}{4} + \frac{1}{4} \right\} = 0.
\]

(95)

The above is just the result of the rigorous NLO calculation.

Notice also that the MC result features in a natural way the exponentiation of the distributions like

\[
f(z) = \delta(1-z) + \frac{C_F \alpha_s}{\pi} \left( \frac{\ln(1-z)}{1-z} \right) + \frac{C_F \alpha_s}{\pi} \ln(1-z) \exp \left\{ - \frac{C_F \alpha_s}{\pi} \ln(1-z) \right\}.
\]

such an exponentiation can be included in the analytical formula.

Last but not least, let us write explicitly the difference between the coefficient functions of the standard \(\overline{\text{MS}}\) factorization scheme of Eq. (59) and the MC factorization scheme of Eq. (94).

\[
\Delta C_2(z) = C^\prime_2(z) - C^\prime_2(z) = \frac{C_F \alpha_s}{\pi} \left\{ \frac{1 + z^2}{2(1-z)} \ln \frac{(1-z)^2}{2} + \frac{1}{2} (1-z)^2 \right\}.
\]

(96)

The above function should be used to correct the existing \(\overline{\text{MS}}\) PDFs before using it to fix input in our MC. Alternatively, the coefficient function of Eq. (94) should be used to fit DIS experimental data with the PDF function compatible with the presented MC.

I. Factorization scheme independent relation between DY and DIS processes

In spite of the change of the factorization scheme in the MC, the factorization scheme independent and the regularization-independent relation of AEM (eq. (91) in [30])

\[35\] Here, the usual \(\overline{\text{MS}}\) assignment \(t = y^2 e^{-\mu^2} \) is done, see refs. [39] [40].

\[36\] Similar corrections have to be also determined for the NLO inclusive kernels, once the NLO corrections are included in the ladder part of the MC, see the first incomplete results in ref. [17].
should be reproduced exactly, if we claim to protect the universality. Let us verify it. The original AEM relation reads

$$\Delta_A^{\text{AEM}}(z) = f_{q,DY} - 2f_{q,2}$$

$$= C_F \alpha_s \left[ \delta_{i=1} \left( \frac{2}{3} \alpha_s^2 + \frac{1}{2} \right) + \frac{3}{2} \left( 1 - z \right) + \left( -3 - 2z \right) + \left( 1 + z^2 \right) \left( \frac{\ln(1 - z)}{1 - z} \right) \right]$$

$$= C_F \alpha_s \left[ \delta_{i=1} \left( \frac{2}{3} \alpha_s^2 + \frac{7}{4} \right) + \frac{3}{2} \left( 1 - z \right) + \left( -3 - 2z \right) + \left( 1 + z^2 \right) \left( \frac{\ln(1 - z)}{1 - z} \right) \right] \quad (97)$$

Using the result of the analytical integration of the DIS MC, eq. (94),

$$C_2(z) = \frac{C_F \alpha_s}{\pi} \left\{ \frac{1}{2} + \frac{z^2}{(1 - z)^2} \ln(1 - z) - \frac{3}{4} \left( 1 - z \right) + \left( 1 + z^2 \right) \right\} +$$

and the analogous analytical result for the DY MC of eq. (44)

$$C_2(z) = \delta_{i=1} \left( \frac{2}{3} \alpha_s^2 + \frac{7}{4} \right) + \frac{3}{2} \left( 1 - z \right) + \left( -3 - 2z \right) +$$

we obtain from our two MC implementations the same result

$$C_2(z) - 2C_2^A(z) = \Delta_A^{\text{AEM}}(z). \quad (98)$$

In this way we have reproduced the AEM result for the MC factorization scheme, confirming its universality. The above agreement with the AEM result is easily traced back to the fact that it holds already for the difference of the unsubtracted coefficient functions

$$f_{DY}^{AEM}(z) - 2f_{DY,\text{bare}}^{AEM}(z) = \Delta_A^{\text{AEM}}(z) + 2 \frac{C_F \alpha_s}{\pi} \ln \frac{1}{t} \quad (99)$$

(cf. eqs. (37) and (58)) and because in both MC formulae the same ISR counterterm of eqs. (40) and (64) is subtracted.

In particular, terms due to the $\frac{1}{t}$ component in the $\gamma$-trace present in the DY and DIS coefficient functions necessarily cancel out.

It is fair to mention that in ref. [30] the relation of eq. (97) is treated as the pQCD result for the coefficient function of the DY process in the DIS factorization scheme. On the other hand, this relation can be turned into an experimentally testable relation between the structure functions of the DY and DIS processes, testing the important principle of universality (process independence) of collinear singularities in pQCD predictions, independently of any particular choice of the factorization scheme and the PDFs.

### V. SUMMARY AND OUTLOOK

We have presented a complete method for implementing NLO corrections to the hard process in the LO MC for DY and DIS processes. This method was originally developed for introducing NLO corrections in the ladder MC [15, 16], therefore it is well suited to be extended to include NLO corrections in both hard process and ladder parts.

The presented method is based on a new factorization scheme [16] extending the collinear factorization theorems [4, 26] to the fully exclusive (unintegrated) form, which can serve as a base for the MC distributions. All differences between the $MS$ and this new MC scheme are kept under strict control, and we are elaborating on that in a quite some detail. In particular, we make a powerful cross-check of the whole MC factorization scheme by showing (analytically) that the NLO MC results are reproducing the factorization scheme independent relation of Altarelli–Ellis–Martinelli [30] between the Drell–Yan and DIS processes, see eq. (98).

The main practical results of this work are the multiparton distributions of eq. (54) and eq. (84), for the EW boson production in hadron–hadron collision and electron–hadron deep-inelastic scattering, respectively, which are ready for Monte Carlo implementation. These distributions feature the NLO corrections in the hard process part and the LO pQCD evolution in two multiparton ladder parts. The NLO corrections to the hard process are introduced by means of a single MC weight on top of the LO distributions — it is, therefore, critical that the LO MC covers the multiparton phase space without any gaps or overlaps. This is achieved by means of using the angular ordering, which is also essential for good control of the soft gluon behaviour beyond LO, already in the LO MC. The correct soft limit also assures good behaviour of the MC weight; weights are positive and small (peaked near 1). For the weights distributions and other numerical cross-checks of the presented method we refer reader to ref. [21].

In our opinion this work solves the main obstacles on the way to the NLO MC, based rigorously on the new MC factorization scheme. There are still many less important problems to be solved on the way to the practical level, i.e. construction of the MC program applicable in the LHC data analysis. Let us signal some of these problems and their solutions. (i) For simplicity in our formulas we have omitted the initial PDF of the quark in hadron at low factorization scale $Q \sim 1$ GeV. This can be easily included in the MC. (ii) If we are aiming in a fully NLO MC the ladder parts have to be upgraded to the NLO level, and this work is already well advanced [14, 16]. (iii) In the presented MC scheme the QCD coupling was constant, non-running. It is quite trivial to make it running within the LO MC. It will be less trivial, but also profitable, to disentangle the running-coupling effect from the NLO corrections in the MC implementation of the NLO ladder. This problem is under study and will be treated in a separate publication. (iv) All the MC distributions presented in this work are defined for quarks and gluons, hence in the practical level MC code they will be subject to a hadronization procedure, using one of the existing MC tools, such as HERWIG [8] or PYTHIA [7].

Obviously, the proposed scheme of implementing the NLO
corrections to the hard process combined with the MC parton showers (ladders) is different from the existing ones. In section [3,4] we comment on the differences between our scheme and that of the MC@NLO [9] and POWHEG [11]. More systematic comparisons with these and other schemes [22, 23] will be done separately, at the time of the numerical MC implementation.

The presented method of implementing the NLO corrections to the hard process does not have any principal limitations – it can be extended to more diagrams and other processes. However, at the practical level its application requires that LO parton shower provides for the full coverage (no gaps nor dead zones) of the hard process phase space relevant at NLO level. This requirement is typically not fulfilled by the classic MC parton showers like HERWIG or PYTHIA. It is not excluded that modernized version of these MCs will provide for better phase space coverage, notably using tools developed for the MC@NLO and POWHEG implementations. Otherwise, LO parton shower has to be reconstructed, for instance using scheme proposed in the present work. (This may turn out to be mandatory for implementing NLO corrections in the ladder parts of the parton shower MC.)

Summarizing, this work represents an important step into a new area in the pQCD calculations for hadron colliders in the MC form, in which the NLO corrections are implemented in full compatibility with the re-definition of the hard process combined with the MC parton showers (ladders) is different from the existing ones. In section [3,4] we comment on the differences between our scheme and that of the MC@NLO [9] and POWHEG [11]. More systematic comparisons with these and other schemes [22, 23] will be done separately, at the time of the numerical MC implementation.

The following kinematical variables

\[ x = \frac{\hat{s}}{s} = \frac{(P-k)^2}{P^2} = 1 - \alpha - \beta, \]
\[ P = p_{0F} + p_{0B}, \quad Q = \hat{P} = p_{0F} + p_{0B} - k, \]
\[ s = P^2, \quad \hat{s} = P^2 = (P-k)^2 = P^2 - 2k \cdot P, \]
\[ \alpha = \frac{2k \cdot p_{0B}}{P^2}, \quad \beta = \frac{2k \cdot p_{0F}}{P^2}, \]

are used in this work. The most important of them is the invariant mass squared \( \hat{s} \) of the produced colourless boson.

For the emitted gluons we are using dimensionless eikonal phase space parametrized in terms of various variables:

\[ d^3\mathcal{E}(k) = \frac{d^3k}{2k^0} \frac{1}{k^2} \frac{1}{k^+} \frac{d^2k^0}{k^+} \frac{1}{\alpha \beta} = \frac{\pi \, d\phi \, d\alpha \, da^2}{2 \pi^2 \alpha \beta} = \frac{\pi \, d\phi \, d\alpha \, d\eta}{2 \pi \alpha \beta}, \]

where \( k = (k^1, k^2) \) is a transverse Cartesian 2-vector \( (k_T^2 = |k|^2 = s \alpha \beta) \), the Sudakov (lightcone) variables are

\[ k^\pm = k^0 \pm k^1, \quad \alpha = \frac{2k^+}{\sqrt{s}}, \quad \beta = \frac{2k^-}{\sqrt{s}}. \]

Moreover, we introduce variable \( a = k/\alpha \), and the conventional rapidity variable \( \eta \) is defined as

\[ \eta = \frac{1}{2} \ln \frac{\alpha}{\beta} = \frac{1}{2} \ln \frac{k^+}{k^-} = -\ln \frac{|a|}{\sqrt{s}}, \quad a = |a| = e^{-\eta} \sqrt{s}. \]

Multiparticle phase space is defined as

\[ d\tau_n(P, p_1, p_2, \ldots, p_n) = \delta^{(4)}(P - \sum_{i=1}^n p_i) \prod_{i=1}^n \frac{d^3p_i}{2p_i^0}. \]

The two-dimensional phase space for massless particles is then

\[ d\tau_2(Q, q_1, q_2) = \frac{1}{2} d\Omega. \]
Appendix B: 1-real gluon NLO correction, analytical integration

We are going to integrate analytically 1-real gluon NLO correction as defined in eq. (17). The contribution from the F hemisphere is easily calculable:

\[
\frac{1}{2} C_{2r}(x) = \frac{C_{F} \alpha_{s}}{\pi} \int_{0}^{\infty} d\alpha \int_{0}^{\infty} d\beta \left[ \tilde{P}(x) - \alpha \beta \frac{\alpha_{r} + \beta_{r}}{\alpha_{r}} \right] \bar{\theta}_{\alpha_{r} < \beta_{r}} \bar{\theta}_{\beta_{r} < \alpha_{r}} \bar{\theta}_{\delta_{r} = 1 - \alpha_{r}} \bar{\theta}_{\alpha_{r} < \beta_{r}} \bar{\theta}_{\delta_{r} = 1 - \alpha_{r}}
\]

\[
= \frac{C_{F} \alpha_{s}}{\pi} \left[ \tilde{P}(x) \int_{\Delta} \frac{1}{(1 - x - \beta) \beta} - \int_{\Delta} \frac{1}{(1 - x) \beta} \right]
\]

\[
= \frac{C_{F} \alpha_{s}}{\pi} \left[ \tilde{P}(x) \int_{0}^{(1-x)/2} \frac{db}{1 - x - \beta} + \int_{0}^{(1-x)/2} \frac{db}{\beta} - \int_{\Delta} \frac{db}{\beta} \right] - \frac{C_{F} \alpha_{s} 1 - x}{\pi 2} = - \frac{C_{F} \alpha_{s} 1 - x}{\pi 2}
\]

Appendix C: Inclusive NLO factorization formula for DY MC

We are going to prove the formula of eq. (26), representing the MC with two LO ladders and the NLO-corrected hard process, by means of reorganizing the phase space integration of eq. (34). Let us consider the part of the total cross section of eq. (34) proportional to the term \( j \in F \) in the MC weight of eq. (25). The summation and integration over the “spectator” LO gluons in the B part of the phase space can be easily folded into the LO PDF. What remains to be considered is the following sum of integrals:

\[
\sigma_{F}^{NLO} = \int d\xi_{F} d\delta_{z_{F}} \prod_{j=1}^{n_{1}} e^{-S_{F}} \int_{0}^{\infty} \left( \prod_{i=1}^{n_{i}} d^{3}E(k_{i}) \theta_{\eta_{i} < \eta_{i-1}} \right) \frac{2C_{F} \alpha_{s}}{\pi^{2}} \bar{P}(z_{F}) \sum_{j \in F} \tilde{B}_{1}(\hat{\delta}, \hat{\rho}_{F}, \hat{\rho}_{B}, a_{j}, z_{F}) G_{B}(\xi_{F}, x_{B}) \delta_{x_{F} = \eta_{j} z_{F}}
\]

\[
= \int d\xi_{F} d\delta_{z_{F}} \sum_{j=1}^{n_{1}} e^{-S_{F}} \int \left( \prod_{i=1}^{n_{i}} d^{3}E(k_{i}) \theta_{\eta_{i} < \eta_{i-1}} \right) \frac{2C_{F} \alpha_{s}}{\pi^{2}} \bar{P}(z_{F}) \left( \sum_{j \in F} \tilde{B}_{1}(\hat{\delta}, \hat{\rho}_{F}, \hat{\rho}_{B}, a_{j}, z_{F}) G_{B}(\xi_{F}, x_{B}) \delta_{x_{F} = \eta_{j} z_{F}} \right)
\]

\[
\times \int d^{3}E(k_{0}) \theta_{\eta_{0} < \eta_{0-1}} \sum_{j=1}^{n_{j-1}} \tilde{B}_{1}(\hat{\delta}, \hat{\rho}_{F}, \hat{\rho}_{B}, a_{j}, z_{F}) G_{B}(\xi_{F}, x_{B}) \delta_{x_{F} = \eta_{j} z_{F}} \prod_{j=1}^{n_{j-1}} z_{F_{j}}
\]

The essential step in transforming each \( j \)-th term is relabelling the gluons \( i \rightarrow i' \) such that \( i' = i \) for \( i = 1, 2, ..., j - 1 \) and \( i' = i - 1 \) for \( i = j + 1, ..., n_{1} \), hence \( i' = 1, 2, ..., n_{1} - 1 \) without any gap, and finally \( i = j \) is relabelled as \( j' = 0 \). Using the symmetry of the integrand, integrals over \( k_{F} \) can be pulled out, and the sum over adjacent integration ranges of \( k_{F} = k_{0} \) is factorized off:

\[
\sigma_{F}^{NLO} = \int d\xi_{F} d\delta_{z_{F}} \prod_{j=1}^{n_{1}} e^{-S_{F}} \int \left( \prod_{i=1}^{n_{i}} d^{3}E(k_{i}) \theta_{\eta_{i} < \eta_{i-1}} \right) \frac{2C_{F} \alpha_{s}}{\pi^{2}} \bar{P}(z_{F}) \sum_{j \in F} \tilde{B}_{1}(\hat{\delta}, \hat{\rho}_{F}, \hat{\rho}_{B}, a_{j}, z_{F}) G_{B}(\xi_{F}, x_{B}) \delta_{x_{F} = \eta_{j} z_{F}} \prod_{j=1}^{n_{j-1}} z_{F_{j}}
\]

\[
\times \sum_{j=1}^{n_{j-1}} \int d^{3}E(k_{0}) \theta_{\eta_{0} < \eta_{0-1}} \tilde{B}_{1}(\hat{\delta}, \hat{\rho}_{F}, \hat{\rho}_{B}, a_{j}, z_{F}) G_{B}(\xi_{F}, x_{B}) \delta_{x_{F} = \eta_{j} z_{F}} \prod_{j=1}^{n_{j-1}} z_{F_{j}}
\]

The sum over the adjacent integration intervals is combined into a single integral

\[
\int_{a_{1}}^{a_{2}} \tilde{B}_{1} d\alpha_{0} + \int_{a_{2}}^{a_{3}} \tilde{B}_{1} d\alpha_{0} + \int_{a_{3}}^{a_{4}} \tilde{B}_{1} d\alpha_{0} \cdots + \int_{a_{n_{1}-2}}^{a_{n_{1}-1}} \tilde{B}_{1} d\alpha_{0} = \int_{0}^{a_{n_{1}-1}} \tilde{B}_{1} d\alpha_{0}
\]

and factorized off, while the remaining integrals over the spectator gluons \( i' = 1, 2, ..., n_{1} - 1 \) give rise to the LO PDF:

\[
\sigma_{F}^{NLO} = \int d\xi_{F} d\xi_{F'} d\delta_{z_{F}} \prod_{j=1}^{n_{1}} e^{-S_{F}} \int \left( \prod_{i=1}^{n_{i}} d^{3}E(k_{i}) \theta_{\eta_{i} < \eta_{i-1}} \right) \frac{2C_{F} \alpha_{s}}{\pi^{2}} \bar{P}(z_{F}) \delta_{x_{F} = \eta_{j} z_{F}} \prod_{j=1}^{n_{j-1}} z_{F_{j}}
\]

\[
\times \int d^{3}E(k_{0}) \tilde{B}_{1}(\hat{\delta}, \hat{\rho}_{F}, \hat{\rho}_{B}, a_{j}, z_{F}) G_{B}(\xi_{F}, x_{B}) \delta_{x_{F} = \eta_{j} z_{F}} \prod_{j=1}^{n_{j-1}} z_{F_{j}}
\]

\[
= \int d\xi_{F} d\xi_{F'} d\delta_{z_{F}} \left( G_{F}(\xi_{F}, x_{F}) G_{B}(\xi_{F}, x_{B}) \frac{1}{2} C_{2r}(z_{F}) \sigma_{B}(xx) \delta_{x=x_{F},x'=z_{F}} \right)
\]
where we have replaced the integration variable $x_F$ with $z_F = x_F/x_F'$. In the last step we were able to use the integral defined in eq. (17) and evaluated in Appendix B of ref. [31].

The other part of the total cross section of eq. (34) proportional to the term $j \in B$ in the MC weight of eq. (35) gives the same result. For the LO part times $(1 + \delta_{B+})$ we use eq. (31).

As already noted, the key part of the above algebra is reminiscent of that in ref. [36], except that here the resummed singularities are in the angle while in ref. [36] they are in the energy variable.
