Abstract. Relative dimensions of isotypic components of $N$–th order tensor representations of the symmetric group on $n$ letters give a Plancherel–type measure on the space of Young diagrams with $n$ cells and at most $N$ rows. It was conjectured by G. Olshanski that dimensions of isotypic components of tensor representations of finite symmetric groups, after appropriate normalization, converge to a constant with respect to this family of Plancherel–type measures in the limit when $\frac{N}{\sqrt{n}}$ converges to a constant. The main result of the paper is the proof of this conjecture.

1. Introduction

Let $N$ and $n$ be two positive integers, let $S_n$ be the symmetric group on $n$ letters and let $\mathcal{Y}^n$ be the set of Young diagrams with $n$ cells. The finite dimensional irreducible representations of $S_n$ are parametrized by the set $\mathcal{Y}^n$. Given $\lambda \in \mathcal{Y}^n$ let $V_\lambda$ be the irreducible representation of $S_n$ corresponding to the Young diagram $\lambda$ and denote $\dim \lambda = \dim V_\lambda$.

The $N$-th order tensor representation of $S_n$ is the action of $S_n$ on the tensor product space $(\mathbb{C}^N)^\otimes n$ by permuting the factors in the tensor product. We are interested in isotypic components of these representations.

If $V$ is an irreducible subrepresentation of a representation $U$ of a finite group, the isotypic component of $U$ corresponding to $V$ is defined to be the sum of all subrepresentations of $U$ which are isomorphic to $V$. It is easy to show that $U$ decomposes uniquely into a direct sum of its isotypic components.

Let $\mathcal{Y}_N^n$ denote the set of Young diagrams with $n$ cells and at most $N$ rows. It follows from Schur–Weyl duality [Wey39, FH91] between the symmetric group $S_n$ and the general linear group $GL(N, \mathbb{C})$ that the irreducible representations of $S_n$ which are subrepresentations of the representation $(\mathbb{C}^N)^\otimes n$ are exactly the ones which correspond to Young diagrams in the set $\mathcal{Y}_N^n$. Given $\lambda \in \mathcal{Y}_N^n$ let $E_\lambda$ denote the isotypic component of $(\mathbb{C}^N)^\otimes n$ corresponding to $V_\lambda$. Decomposing $(\mathbb{C}^N)^\otimes n$ into a direct sum of its isotypic components and looking at dimensions, we obtain

$$N^n = \sum_{\lambda \in \mathcal{Y}_N^n} \dim E_\lambda.$$

Introduce a probability measure on $\mathcal{Y}_N^n$ given by relative dimensions of the corresponding isotypic components:

$$P^N_N(\lambda) = \frac{\dim E_\lambda}{N^n}.$$

We will call the measures $P^N_N(\lambda)$ Schur–Weyl measures.

The main result of this paper is the following theorem on the asymptotics of Schur–Weyl measures, which was conjectured to be true by G. Olshanski:

**Theorem 1.1.** For any $c > 0$, $c \neq 1$ there exists a positive number $H_c$ such that for any $\varepsilon > 0$ we have

$$\lim_{\substack{N \to \infty \\atop \pi \to c}} \lim_{n \to \infty} \mathbb{P}^n_N \left\{ \lambda \in \mathcal{Y}_N^n : \left| -\frac{1}{\sqrt{n}} \ln \frac{\dim E_\lambda}{N^n} - H_c \right| < \varepsilon \right\} = 1.$$
We obtain an explicit, albeit quite complicated formula (43) for the constants $H_c$.

1.1. **Entropy of the Plancherel measure.** A major inspiration for this paper is a theorem of A. Bufetov on the entropy of the Plancherel measure. The Plancherel measure is the measure on $Y^n$ defined by

$$P^n_\lambda = \frac{(\dim \lambda)^2}{n!}.$$

The measure $P^n_\lambda(\lambda)$ can be thought of as an analog of the Plancherel measure for the tensor representations of $S_n$ since in view of Burnside’s theorem $P^n_\lambda(\lambda)$ can be interpreted as the relative dimension of the isotypic component of the regular representation of $S_n$ corresponding to $V_\lambda$. The measure $P^n_\lambda(\lambda)$ can also be thought of as a deformation of the Plancherel measure, since for fixed $n$, the measures $P^n_N$ converge pointwise to the Plancherel measure when $N \to \infty$ (see, for example, [Ols09, Section 3]).

Theorem 1.2 (Theorem 1.1, [Buf10]). There exists a positive constant $H$ such that for any $\varepsilon > 0$ we have

$$\lim_{n \to \infty} P^n_\lambda \left\{ \lambda \in Y^n : \left| -\frac{1}{\sqrt{n}} \ln \frac{(\dim \lambda)^2}{n!} - H \right| < \varepsilon \right\} = 1.$$

By analogy to the Shannon-McMillan-Breiman Theorem, Vershik and Kerov have suggested to call the constant $H$ the entropy of the Plancherel measure. See [Buf10] for details. By the same analogy, $H_c$ can be thought of as the entropy of the family of measures $P^{c^2 N^2}_N$.

1.2. **Outline of the paper.** It was proven by P. Biane [Bia01] that appropriately scaled boundaries of random Young diagrams sampled from $Y^n_N$ according to the Schur–Weyl measures converge to a limit shape in the limit $n \to \infty$, $N \to \infty$ and $\frac{n}{N^2} \to c$ (Theorem 2.1). An integral formula for the logarithm of the Schur–Weyl measure $P^n_N(\lambda)$ in terms of the hook lengths and contents of $\lambda$ and the deviation of the boundary of $\lambda$ from the limit shape was obtained in [Mkr12]. In addition, it was shown in [Mkr12] that the limit shape found by Biane is the unique minimizer of this integral, and the quadratic variation was calculated. The starting point of the proof of Theorem 1.1 is this variational formula (Proposition 2.2). Section 2 provides the necessary background.

To study the limit of the variational formula it is necessary to understand the local statistical properties of the boundary of Young diagrams under the Schur–Weyl measures. Toward this end, since it is easier to deal with, we first study the local statistics under the Poissonization of the Schur–Weyl
measures. The first step of the proof is to show that the Poissonization of the measures $\mathbb{P}_N^\infty$ with respect to $n$ are Plancherel–type measures associated with certain extreme characters of the infinite dimensional unitary group (Lemma 3.1). Borodin and Kuan have proven that these Plancherel–type measures are determinantal point processes, have obtained a contour–integral representation of the correlation kernel and have found limits of the process in various regimes. In Section 3 we present the proof that in the case which is of relevance to this paper this determinantal process converges to the discrete sine–process, and using the depoissonization technique of Borodin, Okounkov and Olshanski [BOO00] show that in the limit $N \to \infty$ the local behavior of the boundary of Young diagrams under the Schur–Weyl measures is characterized by the discrete sine–kernel (Proposition 3.7). We also show in Section 3 that the probability of Young diagrams which extend beyond the limit shape at either edge by at least $N^\delta$, $\delta > \frac{1}{3}$, is exponentially small. This statement for the right edge is an immediate corollary of [Joh01, Theorem 1.7].

The next step is to obtain upper bounds for the decay of correlations of the boundary of random Young diagrams. Since the contour–integral formula of Borodin and Kuan is not very suitable for such estimates, using a method of A. Okounkov [Oko02] we obtain a different representation of the correlation kernel and use it to obtain various bounds for the correlation kernel of the poissonized measures (Section 4). We use these estimates to obtain upper bounds on the decay of correlations (Section 4.3).

We use the bounds on the decay of correlations to show in Section 5 that the weighted sum of the indicator functions of the presence of a local pattern on the boundary of a Young diagram converges to a constant with respect to the Schur–Weyl measures. This allows us to show that all the terms in the variational formula for $\mathbb{P}_N^\infty(\lambda)$ which can be characterized in terms of short-range patterns converge to constants.

In Section 6 we show that the terms which correspond to long-range interactions converge to 0 with respect to the Schur–Weyl measures.

1.3. Acknowledgements. I am deeply grateful to Alexander Bufetov for suggesting this problem to me and for numerous useful discussions on the subject. I am very grateful to Grigori Olshanski for helpful discussions. I am very grateful to Alexei Borodin for pointing out the connection to [Joh01]. I am also very grateful to Philippe Biane for bringing [BO07] to my attention.

2. Background

2.1. The limit shape of Young diagrams with respect to Schur–Weyl measures. Represent $\lambda = (\lambda_1 \geq \lambda_2 \geq \ldots \lambda_N) \in \mathbb{Y}_N^\infty$ where $\lambda_i \in \mathbb{N}$ and $\sum \lambda_i = n$ by its diagram as shown in Figure 1. The longest row consists of
The Young diagram \( \lambda = (8, 5, 4, 2, 1, 0) \in \mathcal{Y}^6_{20} \).

\( \lambda_1 \) squares of size 1, the next longest one of \( \lambda_2 \) such squares, and so on. Note that for \( \lambda \in \mathcal{Y}^n_N \), the integer \( N \) is not encoded in the diagram of \( \lambda \).

Scale down the diagram by \( \sqrt{\frac{n}{2}} \) in both directions so that the diagram has area 2 and rotate the scaled diagram by \( \frac{\pi}{4} \) radians as in Figure 2. Let \( L_\lambda(x) \) be the function giving the top boundary of the rotated diagram. Notice that \( L_\lambda(x) \) is a piecewise linear function of slopes \( \pm 1 \) and that \( L_\lambda(x) = |x| \) for \( x \gg 1 \) and \( x \leq -\frac{N}{\sqrt{n}} \).

P. Biane [Bia01] has proven that in the limit \( n \to \infty \), \( \sqrt{n}/N \to c \) the boundary of a random scaled Young diagram sampled from the measure \( \mathbb{P}^n_N \) converges in measure to a limit shape. The limit shape \( \Omega_c(s) \) is described in the following way. For \( x \in [c - 2, c + 2] \),

\[
\Omega_c(x) = \frac{1}{\pi} \left( 2x \arcsin \left( \frac{x + c}{2\sqrt{1 + xc}} \right) + \frac{2}{c} \arccos \left( \frac{2 + xc - c^2}{2\sqrt{1 + xc}} \right) + \sqrt{4 - (x - c)^2} \right),
\]
otherwise
\[
\Omega_c(x) = \begin{cases} 
|x|, & 0 < c \leq 1 \text{ and } x \notin [c - 2, c + 2] \\
|x|, & 1 < c \text{ and } x \notin [-\frac{1}{c}, c + 2] \\
x + \frac{2}{c}, & 1 < c \text{ and } x \in [-\frac{1}{c}, c - 2]
\end{cases}
\]

The precise formulation of Biane's theorem is the following law of large numbers for the measures \(P^n_N\).

**Theorem 2.1** (Theorem 3, [Bia01]). Let \(N = N(n)\) be such that
\[
\lim_{n \to \infty} \frac{\sqrt{n}}{N(n)} = c \geq 0.
\]

For any fixed \(\varepsilon > 0\) we have
\[
\lim_{n \to \infty} \mathbb{P}_N^n \{ \lambda \in \mathbb{Y}_N^n : \forall x \in \mathbb{R}, |L_\lambda(x) - \Omega_c(x)| < \varepsilon \} = 1.
\]

Figure 3 gives graphs of \(\Omega_c(x)\) for several values of \(c\). For every \(c\) the graph of the function \(\Omega_c(x)\) intersects the graph of \(|x|\) at two points. All the intersections are tangential except the intersections on the left side for \(c \geq 1\). At the left intersection point \(\Omega_1(x)\) has slope 0 from the right, while \(\Omega_c(x)\) for \(c > 1\) has slope 1 from the right.

**Note:** We prove Theorem 1.1 only in the case \(c \neq 1\). The case \(c = 1\) cannot be treated together with the other cases, because the nature of the fluctuations of \(L_\lambda\) near the left intersection point of the graph of \(\Omega_1(x)\) with the graph of \(|x|\) is different from the other cases. The main reason the nature of the fluctuations changes is the transversal intersection of the nonlinear section of the limit shape with the linear section as indicated in Figure 3. The nature
of fluctuations near this intersection point has been studied by Borodin and Olshanski [BO07].

Notice that $\Omega_c(x)$ has a rather simple derivative:

$$
\Omega'_c(x) = \begin{cases} 
\frac{2}{\pi} \arcsin \left( \frac{c+x}{2\sqrt{1+x^2}} \right), & x \in [c-2, c+2] \\
1, & x > c+2, \text{ or } 1 < c \text{ and } x \in [-\frac{1}{c}, c-2], \\
-1, & \text{otherwise} 
\end{cases}
$$

The limit shape $\Omega_c(x)$ is a continuous deformation (depending on $c$) of the limit shape of random scaled Young diagrams sampled according to the Plancherel measure, which was found independently and simultaneously by Vershik and Kerov [VK77], and Logan and Shepp [LS77]. The Vershik-Kerov-Logan-Shepp limit shape is obtained when $c = 0$.

2.2. A variational formula for the measures. Let $i$ index the rows and $j$ the columns of a Young diagram. For the cell at position $(i,j)$ in a Young diagram $\lambda$ define the numbers $p_{i,j} \in \mathbb{Z} + \frac{1}{2}$ and $q_{i,j} \in \mathbb{Z} + \frac{1}{2}$ to be $\frac{1}{2}$ plus the number of cells to the right of and respectively above the cell as shown in Figure 4. Define the hook length of the cell at position $(i,j)$ to be $h_{i,j} = p_{i,j} + q_{i,j}$ and the content to be $c_{i,j} = j - i$.

For a statement $S$ denote

$$
\delta_S = \begin{cases} 
1, & S \text{ is true} \\
0, & S \text{ is false} 
\end{cases}
$$

The following variational formula for the measures $\mathbb{P}_N^n$ was obtained in [Mkr12].

**Proposition 2.2** (Propositions 2.1 and 3.1, [Mkr12]). Let $c = c_{n,N} = \frac{\sqrt{n}}{N} > 0$. We have

$$
- \frac{\ln \mathbb{P}_N^n(\lambda)}{\sqrt{n}} = \frac{\sqrt{n}}{8} \|f_\lambda\|_2^2 + \frac{\sqrt{n}}{2} \int_{|x-c| > 2} G_c(x)f_\lambda(x) \, dx + \hat{\theta}(\lambda) - \hat{\rho}(\lambda) - \varepsilon_n,
$$
where \( f_\lambda(x) = L_\lambda(x) - \Omega_c(x) \),

\[
\| f \|_2^2 = \int \int \left( \frac{f(s) - f(t)}{s - t} \right)^2 \, ds \, dt
\]

is the \( \frac{1}{2} \)-Sobolev norm in the space of piecewise-smooth functions,

\[
G_c(x) = \delta_{|x-c|>2} \left( \text{arccosh} \left| \frac{x - c}{2} \right| + \text{sign}(1 - c) \text{arccosh} \left| \frac{3c - c^3 + (1 + c^2)x}{2(1 + cx)} \right| \right),
\]

\[
\hat{\theta}(\lambda) = \frac{1}{\sqrt{n}} \sum_{i,j} m(h_{i,j}),
\]

\[
\hat{\rho}(\lambda) = \frac{1}{2\sqrt{n}} \sum_{i,j} m(N + c_{i,j}),
\]

\[
m(x) = \sum_{k=1}^{\infty} \frac{1}{k(k+1)(2k+1)2^{2k}},
\]

and \( \varepsilon_n = o \left( \frac{\ln n}{\sqrt{n}} \right) \) is independent of \( \lambda \). The sums in \( \hat{\theta} \) and \( \hat{\rho} \) range over all cells of \( \lambda \).

Using the variational formula (2) it is not very hard to prove that the random variables \( \frac{1}{\sqrt{n}} \ln \frac{\dim E_\lambda}{N^n} \) are bounded in measure with respect to \( \mathbb{P}^n_N \) \cite{Mkr12}:

**Theorem 2.3 (Theorem 1.2, \cite{Mkr12}).** For any \( c > 0 \) there exist positive numbers \( \alpha_c \) and \( \beta \) such that if

\[
\lim_{n \to \infty} \frac{\sqrt{n}}{N} = c,
\]

then

\[
\lim_{n \to \infty} \mathbb{P}^n_N \left\{ \lambda : \alpha_c < -\frac{1}{\sqrt{n}} \ln \frac{\dim E_\lambda}{N^n} < \beta \right\} = 1.
\]

In contrast, Theorem 1.1 states that the random variables \( \frac{1}{\sqrt{n}} \ln \frac{\dim E_\lambda}{N^n} \) converge to constants with respect to \( \mathbb{P}^n_N \). It was proven in \cite{Mkr12} that the quantities \( \frac{1}{\sqrt{n}} \ln \frac{\max_{\lambda \in \mathcal{Y}_N^n} \{\dim E_\lambda\}}{N^n} \) are also bounded.

**Theorem 2.4 (Theorem 1.1, \cite{Mkr12}).** For any \( c > 0 \) there exist positive numbers \( \alpha_c \) and \( \beta \) such that for large enough \( n \in \mathbb{N} \) and for any \( N \in \mathbb{N} \), if \( c > \frac{\sqrt{n}}{N} \), then

\[
\alpha_c < -\frac{1}{\sqrt{n}} \ln \frac{\max_{\lambda \in \mathcal{Y}_N^n} \{\dim E_\lambda\}}{N^n} < \beta.
\]
Analogous results to Theorems 2.3 and 2.4 for the Plancherel measures were obtained by Vershik and Kerov in 1985 [VK85]. Numerical simulations by Vershik and Pavlov [VP10] suggest that for the Plancherel measures the typical dimensions converge in measure (Theorem 1.2 by A. Bufetov). However, their simulations suggest that perhaps no such convergence holds for the maximal dimensions.

2.3. Plancherel type measures for the infinite-dimensional unitary group. As mentioned in the Introduction, we will need to study the poissonization of the Schur–Weyl measures. The poissonized measures are closely related to measures on signatures of length \(N\) corresponding to certain extreme characters of the infinite dimensional unitary group, which we now introduce.

Let \(U = U(1)\) be the group of all \(1 \times 1\) unitary matrices. There is a natural embedding of \(U \hookrightarrow U(2)\) given by
\[
U \ni U \mapsto \begin{pmatrix} U & 0 \\ 0 & 1 \end{pmatrix} \in U(2).
\]

Define the infinite dimensional unitary group \(U(\infty)\) to be
\[
U(\infty) = \bigcup_{N=1}^{\infty} U(N).
\]

Let \(\mathcal{G}_N\) be the set of signatures of length \(N\), i.e. the set of sequences \(\lambda\) of \(N\) nonnegative nonincreasing integers: \(\lambda = (\lambda_1 \geq \lambda_2 \geq \ldots \geq \lambda_N)\), \(\lambda_i \in \mathbb{Z}\).

It is well known that the irreducible highest–weight representations of \(U(N)\) are parametrized by the set \(\mathcal{G}_N\). For \(\lambda \in \mathcal{G}_N\) let \(W_\lambda\) denote the irreducible representation of \(U(N)\) with highest–weight \(\lambda\), and let \(\chi_\lambda\) and \(\dim N \lambda\) be respectively the character and dimension of \(W_\lambda\). Note that \(\chi_\lambda(e) = \dim N \lambda\), where \(e\) is the identity. Define the normalized character \(\tilde{\chi}_\lambda\) as
\[
\tilde{\chi}_\lambda = \frac{\chi_\lambda}{\dim N \lambda}.
\]

The notion of a normalized character can be generalized to groups such as \(U(\infty)\). A normalized character of \(U(\infty)\) is a positive-definite continuous function \(\chi\) which is invariant under conjugation and satisfies the condition \(\chi(e) = 1\). The set of normalized characters of \(U(\infty)\) is a convex set and the extreme characters of \(U(\infty)\) are defined to be the extreme points of this set.

Extreme characters of \(U(\infty)\) can be approximated by the normalized characters of \(U(N)\) when \(N\) goes to infinity. Here we will present the exact statement of this result only in the specific case of interest to us. For a more general discussion of extreme characters of \(U(\infty)\) and for proofs see for example [VK82], [OO98], [BK08] or [BO12].

A signature \(\lambda\) can be represented by two Young diagrams \((\lambda^+, \lambda^-)\) corresponding to its positive and negative parts. If \(\lambda^+ = (\lambda_1^+ \geq \lambda_2^+ \geq \ldots \geq 0)\) and
\[ \lambda^- = (\lambda_1^- \geq \lambda_2^- \geq \ldots \geq 0), \text{ then } \lambda = (\lambda_1^+ \geq \lambda_2^+ \geq \ldots \geq -\lambda_2^+ \geq -\lambda_1^-). \]

Let \( \lambda^{\pm}' \) be the transposes of \( \lambda^{\pm} \), i.e. the number of cells in the \( i \)-th row of \( \lambda^{\pm}' \) is equal to the number of cells in the \( i \)-th column of \( \lambda^{\pm} \).

For a Young diagram \( \mu \) let \( |\mu| \) denote the number of boxes in \( \mu \) and let \( d(\mu) \) denote the number of cells on the diagonal of \( \mu \). The numbers \( p_i(\mu) := p_{i,i}(\mu) \) and \( q_i(\mu) := q_{i,i}(\mu), \ 1 \leq i \leq d(\mu) \) are called Frobenius coordinates of the Young diagram \( \mu \) (see Figure 4). They completely determine \( \mu \).

**Theorem 2.5** ([VK82]). For any extreme character \( \chi \) of \( U(\infty) \) there exists a unique set of constants \( \alpha_1^+ \geq \alpha_2^+ \geq \ldots \geq 0, \beta_1^+ \geq \beta_2^+ \geq \ldots 0 \) and \( \delta^+ \geq 0 \), satisfying the conditions
\[
\sum_{i=1}^{\infty} (\alpha_i^+ + \beta_i^+) < \delta^+, \quad \beta_1^+ + \beta_1^- \leq 1,
\]
and such that for any sequence of signatures \( \lambda(N) \in GT_N \), if
\[
\lim_{N \to \infty} \frac{p_i(\lambda(N)^+)}{N} = \alpha_i^+, \quad \lim_{N \to \infty} \frac{q_i(\lambda(N)^-)}{N} = \beta_i^+ \text{ and } \lim_{N \to \infty} \frac{|\lambda(N)|}{N} = \delta^+,
\]
then the normalized characters \( \tilde{\chi}^{\lambda(N)} \) approximate \( \chi \).

Set
\[
\gamma^+ = \delta^+ - \sum_{i=1}^{\infty} (\alpha_i^+ + \beta_i^+) \geq 0.
\]

Let \( \chi^{\gamma^+, \gamma^-} \) denote the characters which according to Theorem 2.5 can be approximated by \( \tilde{\chi}^{\lambda(N)} \) with \( \alpha_i^+ = \beta_i^+ = 0 \). In other words, \( \chi^{\gamma^+, \gamma^-} \) correspond to limits of \( \tilde{\chi}^{\lambda(N)} \) when the rows and columns of \( \lambda^+(N) \) grow sublinearly in \( N \) and \( |\lambda^+(N)| \) grow as \( \gamma^+ N \).

D. Voiculescu [Voi76] gave a complete description of extreme characters of \( U(\infty) \). In particular, given \( U \in U(\infty) \), for \( \chi^{\gamma^+, \gamma^-} \) we have
\[
\chi^{\gamma^+, \gamma^-}(U) = \prod_{u \in \text{Spectrum}(U)} e^{\gamma^+ (u-1) + \gamma^- (u^{-1}) - 1}.
\]

Given a character \( \chi \) of \( U(\infty) \), consider its restriction to \( U(N) \). It can be decomposed into a nonnegative linear combination of irreducible, and hence normalized irreducible characters of \( U(N) \). Write
\[
\chi|_{U(N)} = \sum_{\lambda \in GT_N} \mathbb{P}_N^\chi(\lambda) \tilde{\chi}^\lambda.
\]

\( \mathbb{P}_N^\chi(\lambda) \) gives a probability measure on \( GT_N \). Let \( \mathbb{P}_N^{\gamma^+, \gamma^-} \) be the measure corresponding to the extreme character \( \chi^{\gamma^+, \gamma^-} \).
3. Poissonization and depoissonization

All statements that follow are proven for arbitrary $c \in (0, 1) \cup (1, \infty)$, however no uniformity in $c$ is established. In particular all constants may depend on $c$, but to simplify notation this dependence will not be indicated explicitly.

### 3.1. Poissonization of Schur–Weyl measures

Recall that the Poisson distribution with rate $\mu$ is

$$\text{Pois}_\mu(n) = e^{-\mu} \frac{\mu^n}{n!}.$$ 

If $\{\mathbb{P}^n\}_{n \in \mathbb{N}}$ is a family of measures with distinct supports $\{S_n\}_{n \in \mathbb{N}}$, its poissonization with parameter $\nu$ is the measure $\text{Pois}_{\mathbb{P},\nu}$ with support $S := \bigcup_{n \in \mathbb{N}} S_n$ and defined by

$$\text{Pois}_{\mathbb{P},\nu}(x) = e^{-\nu} \frac{\nu^n}{n!} \mathbb{P}^n(x),$$

where $\mathbb{P}^n$ is naturally extended to $S$ by setting $\mathbb{P}^n(S \setminus S_n) = 0$.

Let $\mathbb{P}_{\nu,N}$ denote poissonization of the family of measures $\mathbb{P}^n_N$ with respect to $n$. It is a one–parameter family of measures on $\bigcup_{n \in \mathbb{N}} \mathbb{Y}^n_N$ defined by

$$\mathbb{P}_{\nu,N}(\lambda) = e^{-\nu} \frac{\nu^n}{n!} \mathbb{P}^n_N(\lambda) \quad \text{if} \quad \lambda \in \mathbb{Y}^n_N.$$

**Lemma 3.1.** The measure $\mathbb{P}^{\gamma^+,0}_N$ is the poissonization of the measure $\mathbb{P}^n_N$ with respect to $n$. The poissonization parameter is $\nu = \gamma^+ N$.

**Proof.** We need to show that $\mathbb{P}_{\gamma^+,N,N} = \mathbb{P}^{\gamma^+,0}_N$. By (6) it is enough to show that

$$\chi^{\gamma^+,0}_{U(N)} = \sum_{\lambda \in \mathbb{Y}^n_N} \mathbb{P}_{\gamma^+,N,N}(\lambda) \frac{\chi^\lambda}{\dim_N \lambda}.$$

By (5), for $U \in U(N)$,

$$\chi^{\gamma^+,0}(U) = e^{\gamma^+ \text{tr}U - \gamma^+ N}.$$

It is a consequence of Schur–Weyl duality [FH91] that $E_\lambda = V_\lambda \otimes W_\lambda$. Hence

$$\mathbb{P}^n_N(\lambda) = \frac{\dim E_\lambda}{N^n} = \frac{\dim \lambda \dim N \lambda}{N^n},$$
which implies
\[
\sum_{\lambda \in \mathbb{G}T_N} \mathbb{P}_{\gamma^+,N}(\lambda) \frac{\chi^\lambda(U)}{\dim_N \lambda} = \sum_{\lambda \in \mathbb{G}T_N} e^{-\gamma^+ N} \frac{(\gamma^+ N)^n}{n!} \mathbb{P}_N^n(\lambda) \frac{\chi^\lambda(U)}{\dim_N \lambda} \\
= \sum_{\lambda \in \mathbb{G}T_N} e^{-\gamma^+ N} \frac{(\gamma^+ N)^n}{n!} \dim \lambda \dim_N \frac{\chi^\lambda(U)}{\dim_N \lambda} \\
= \sum_{\lambda \in \mathbb{G}T_N} e^{-\gamma^+ N} \frac{(\gamma^+ N)^n}{n!} \dim \lambda \chi^\lambda(U) \dim \lambda.
\]

Let \( \mathbb{G}T^n_N \) be the set of signatures \( \lambda \in \mathbb{G}T_N \) which have only nonnegative terms and for which \( \sum_i \lambda_i = n \). Note that \( \mathbb{G}T^n_N \) coincides with the set \( \mathbb{Y}^n_N \). We obtain
\[
\sum_{\lambda \in \mathbb{G}T^n_N} \mathbb{P}_{\gamma^+,N,N}(\lambda) \frac{\chi^\lambda(U)}{\dim_N \lambda} = \sum_{n=0}^{\infty} e^{-\gamma^+ N} \frac{(\gamma^+ N)^n}{n!} \sum_{\lambda \in \mathbb{G}T^n_N} \chi^\lambda(U) \dim \lambda \\
= \sum_{n=0}^{\infty} e^{-\gamma^+ N} \frac{(\gamma^+ N)^n}{n!} (\mathcal{C}^N)^\otimes n (U) \\
= \sum_{n=0}^{\infty} e^{-\gamma^+ N} \frac{(\gamma^+ N)^n}{n!} (trU)^n \\
= e^{-\gamma^+ N} \sum_{n=0}^{\infty} \frac{(\gamma^+ trU)^n}{n!} = e^{\gamma^+ trU - \gamma^+ N},
\]
which completes the proof.

If certain conditions are met (see Lemma \[3.4\]), properties of a family of measures \( \mathbb{P}^n \) when \( n \to \infty \) can be obtained from analogous properties of the poissonization \( \text{Pois}_{\mathbb{P},\nu} \) of those measures when \( \nu \to \infty \):
\[
\mathbb{P}^n(x) \approx \text{Pois}_{\mathbb{P},\nu}(x), \quad \text{when } \nu \approx n \gg 1.
\]

According to Lemma \[3.1\] the poissonization of \( \mathbb{P}^n_N \) with respect to \( n \) with parameter \( \nu \) gives \( \mathbb{P}^n_{\nu} \). Since we are interested in properties of \( \mathbb{P}^n_N \) in the limit when \( n \to \infty \) so that \( \frac{\sqrt{n}}{N} \to c \), the relevant limit of the poissonized measures \( \mathbb{P}^n_{\nu^+,0} \) for us is when the poissonization parameter \( \gamma^+ \) converges to infinity so that \( \frac{\sqrt{\gamma^+ N}}{N} \to c \), or equivalently that \( \gamma^+ \to c^2 \).

3.2. The poissonized measures as determinantal point processes. Associate with each \( \lambda \in \mathbb{G}T_N \) the point configuration
\[
\mathcal{P}(\lambda) := \{\lambda_1 - 1, \lambda_2 - 2, \ldots, \lambda_N - N\} \subset \mathbb{Z}.
\]
Under this correspondence the pushforward of $\mathbb{P}_N^{\gamma,0}$ is a random $N$-point process on $\mathbb{Z}$. See Figure 5 for a visualization of this correspondence. Note, that since the measure $\mathbb{P}_N^{\gamma,0}$ is supported on Young diagrams with at most $N$ rows, we are working with configurations which are subsets of $[-N, \infty)$.

Borodin and Kuan have proven that the point process corresponding to $\mathbb{P}_N^{\gamma,0}$ is determinantal.

**Theorem 3.2 (Theorem 3.2, [BK08]).** The point process $\mathbb{P}_N^{\gamma,0}$ is determinantal: for arbitrary $x_1, \ldots, x_k \in \mathbb{Z}$,

$$\mathbb{P}_N^{\gamma,0}\{\lambda : \{x_1, \ldots, x_k\} \subset \mathcal{P}(\lambda)\} = \det[K_{N,\gamma}(x_i, x_j)]_{1 \leq i, j \leq k}.$$  

The correlation kernel $K_{N,\gamma}$ is given by

$$K_{N,\gamma}(x, y) = \frac{1}{(2\pi)^2} \int_{|u| = r} \int_{|w-1| = r} \frac{e^{u^{-1}} u^{x} (1 - u)^{N}}{e^{w^{-1}} w^{1+y}(1 - w)^{N}} \frac{du}{u - w},$$

where $r$ is any constant in $(0, \frac{1}{2})$.

**Note:** The theorem as stated here is a special case of the theorem of Borodin and Kuan. The theorem in [BK08] deals with point processes corresponding to measures on paths in the Gelfand-Tsetlin graph $\mathcal{G}$ which arise from extreme characters of $U(\infty)$ corresponding to arbitrary parameters $(\alpha_i^\pm, \beta_i^\pm, \gamma^\pm)$.

Given an integer $k$ and a subset $X \subset \mathbb{Z}$, define

$$c_k(X) = \begin{cases} 1 & k \in X \\ 0 & k \notin X \end{cases}.$$  

Given an integer vector $\vec{m} = \{m_1, \ldots, m_r\}$, define

$$c_{\vec{m}}(X) = c_{m_1}(X) \ldots c_{m_r}(X).$$
For a Young diagram $\lambda$, let
\[ c_\vec{m}(\lambda) = c_\vec{m}(\mathcal{P}(\lambda)). \]

In terms of the introduced notation the statement of Theorem 3.2 is equivalent to
\[ \mathbb{E}_{\mathbb{P}_N^{\gamma+,0}} c_{\{x_1, \ldots, x_k\}} = \det[K_{N,\gamma^+}(x_i, x_j)]_{1 \leq i, j \leq k}. \]

Another characterization of the poissonization of the measure $\mathbb{P}_N^n$ is as the Charlier orthogonal polynomial ensemble, which was proven by K. Johansson [Joh01]. Thus, the determinantal process with kernel $K_{N,\gamma^+}$ coincides with the determinantal process with the Christoffel-Darboux kernel of the Charlier ensemble. Since operators given by Christoffel-Darboux kernels are projection operators [Ols08], it follows that the operator given by $K_{N,\gamma^+}$ is also a projection operator. In particular, it follows that
\[ K_{N,\gamma^+}(x, x) = \sum_{y \in \mathbb{Z}} K_{N,\gamma^+}(x, y) K_{N,\gamma^+}(y, x) \]
for all $x$.

3.2.1. The discrete sine-process. Define the discrete sine kernel to be the function
\[ S(l, t) = \begin{cases} \frac{\sin(lt)}{\pi t}, & l \neq 0 \\ \frac{t}{\pi}, & l = 0 \end{cases}. \]
Let $S(t)$ be the measure on the power set of $\mathbb{Z}$ such that for any $m_1, \ldots, m_r \in \mathbb{Z}$, we have
\[ S(t)\{X \subset \mathbb{Z} : m_1, \ldots, m_r \in X\} = \det[S(m_i - m_j, t)]_{1 \leq i, j \leq r}. \]
The existence of such a measure follows from the general theory of determinantal point processes [Sos00]. The measure $S(t)$ is a point process on $\mathbb{Z}$ called the discrete sine-process. The condition (9) can also be written as
\[ \mathbb{E}_{S(t)}(c_{\vec{m}}) = \det[S(m_i - m_j, t)]_{1 \leq i, j \leq r}. \]
The measure $S(t)$ is translation invariant: if for a constant $a$ we denote $a + \vec{m} = (a + m_1, \ldots, a + m_r)$, we have
\[ \mathbb{E}_{S(t)}(c_{a+\vec{m}}) = \mathbb{E}_{S(t)}(c_{\vec{m}}). \]
3.2.2. Limit of $K_{N,\gamma^+}$. We show that the determinantal process given by $K_{N,\gamma^+}$ converges to the discrete sine-process when $N \to \infty$, $\frac{\gamma^+}{N} \to c^2$. Define the function
\[ A_x(z) = c^2 z^{-1} + x c \ln(z) + \ln(1 - z). \]
Differentiating $A$ with respect to $z$ we obtain
\[ z^2(z - 1)A'_x(z) = (1 + cx)z^2 - (c^2 + cx)z + c^2. \]
If $A_x'(z)$ has nonreal roots, let $z_x^+$ be the root of $A_x'(z)$ such that $\Im z_x^+ > 0$:

$$z_x^+ = \frac{c^2 + cx + ic\sqrt{4 - (x - c)^2}}{2(1 + cx)}.$$  

If $A_x'(z)$ has real roots, $z_x^+$ is the larger one. Note that $z_x^+ \neq 0$. Let $z_x^-$ be the other root and denote $\phi_x = \arg(z_x^+)$. Notice that

$$|z_x^\pm|^2 = \frac{c^2}{1 + cx}$$

and

$$\phi_x = \arccos \left( \frac{c + x}{2\sqrt{1 + cx}} \right).$$

**Theorem 3.3.** Let $\vec{x} = (x_1, \ldots, x_k)$ depend on $N$ in such a way that $x_i - x_j$ are constant and $\lim_{N \to \infty} \frac{x_i}{N} = x' > -\frac{1}{c}$ for all $1 \leq i, j \leq k$. If $\lim_{N \to \infty} \frac{\gamma^+}{N} = c^2$, then

$$\lim_{N \to \infty} \det[K_{N, \gamma^+}(x_i, x_j)]_{1 \leq i, j \leq k} = \begin{cases} 
\det[S(x_i - x_j, \phi_{x'})]_{1 \leq i, j \leq k}, & |x' - c| < 2 \\
1, & x' - c \leq -2 \\
0, & \text{otherwise} 
\end{cases}$$

**Note:** This is essentially a special case of Theorem 4.6 in [BK08]. The theorem in [BK08] deals with a broader family of kernels in the limit $\frac{\gamma^+}{N} \to a > 0$ and $\frac{\gamma^-}{N} \to b > 0$. For us $b = 0$. The proof presented is an adaptation of the proof in [BK08] to the case $b = 0$. The main reason for presenting a complete proof here is that we will need not only the result, but parts of the proof as well.

**Proof.** To simplify notation, in this proof we write $A(z)$ for $A_{x'}(z)$, $z^+$ for $z_{x'}^+$ and $\phi$ for $\phi_{x'}$. From (7) we obtain

$$K_{N, \gamma^+}(x'cN, x'cN + l)$$

$$= \frac{1}{(2\pi)^2} \oint_{|u| = r} \oint_{|w - 1| = r} e^{N(c^2w^{-1} + x'c\ln(u) + \ln(1-u) + O(\frac{1}{N}))} \frac{du}{u - w} e^{N(c^2w^{-1} + x'c\ln(w) + \ln(1-w) + O(\frac{1}{N}))}$$

$$= \frac{1}{(2\pi)^2} \oint_{|u| = r} \oint_{|w - 1| = r} e^{N(A(u) - A(z^+)) + O(\frac{1}{N}))} \frac{du}{u - w} e^{N(A(w) - A(z^+)) + O(\frac{1}{N}))}$$

We will use the saddle point method to estimate the contour integrals. For that we need to deform the contours of integration to contours $C_u$ and $C_w$, without crossing 0, and 0 or 1 respectively, in such a way that

$$\Re(A(z) - A(z^+)) \leq 0, \ \forall z \in C_u,$$
Figure 6. Deformation of contours in the bulk. The shaded region corresponds to $\Re(A(z) - A(z^+)) < 0$. The solid red (right) and blue (left) contours are the original contours. The dotted red and blue contours are the deformed contours.

and

$$
\Re(A(z) - A(z^+)) \geq 0, \quad \forall z \in C_w.
$$

When $z^\pm$ are not real, i.e. when $|x' - c| < 2$, the contours are deformed as in Figure 6. During the deformation contours cross each other along an arc from $z^-$ to $z^+$ which crosses the real axis between 0 and 1, thus

$$
K_{N,\gamma^+}(x'cN, x'cN + l) = \frac{1}{(2\pi)^2} \int_{C_u} \int_{C_w} e^{N(A(u) - A(z^+)) + O\left(\frac{1}{N}\right)} \frac{du}{u - w} + \frac{1}{(2\pi i)} \int_{z^-}^{z^+} u^{-l-1} du.
$$

In the limit $N \to \infty$ the first integral goes to 0 since the contribution to the integral from points away from the critical points is exponentially small, while at the critical points the contours $C_u$ and $C_w$ cross transversally. Thus, we obtain

$$
\lim_{N \to \infty} K_{N,\gamma^+}(x'cN, x'cN + l) = \frac{1}{(2\pi i)} \int_{z^-}^{z^+} u^{-l-1} du.
$$

Using (12), write $z^+ = \frac{e}{\sqrt{1+cx}} e^{i\beta}$. Making the change of variable $u = \frac{e}{\sqrt{1+cx}} e^{i\theta}$ and evaluating the remaining integral we obtain

$$
\lim_{N \to \infty} K_{N,\gamma^+}(x'cN, x'cN + l) = \left(\frac{c}{\sqrt{1+cx}}\right)^{-l} \times \begin{cases} \sin(\phi l) \pi l, & l \neq 0 \\ \phi \pi, & l = 0 \end{cases}.
$$

When taking a determinant, the gauge terms $\left(\frac{c}{\sqrt{1+cx}}\right)^{-l}$ cancel, and we obtain (14).

The critical points $z^\pm$ are real when $|x' - c| \geq 2$. If $x' - c > 2$, then during the deformation the contours do not cross. Thus, no residues are picked up
Figure 7. Deformation of contours in frozen regions. In the left figure contours do not cross. In the right figure one contour passes over the other. The shaded region corresponds to $\Re(A(z) - A(z^+)) < 0$. The solid red(right) and blue(left) contours are the original contours. The dotted red and blue contours are the deformed contours.

and

$$\lim_{N \to \infty} K_{N,\gamma^+}(x'cN, x'cN + l) = 0.$$  

If $x' - c < -2$, then during the deformation one contour completely passes over the other as in Figure 7. Hence,

$$K_{N,\gamma^+}(x'cN, x'cN + l) = \frac{1}{(2\pi i)^l} \oint_{\tilde{C}} u^{-1-l} du$$

for some closed contour $\tilde{C}$. When $c < 1$, the contour $\tilde{C}$ winds around 0 once and we have

$$\lim_{N \to \infty} K_{N,\gamma^+}(x'cN, x'cN + l) = \begin{cases} 1, & l = 0 \\ 0, & l \neq 0 \end{cases}.$$  

When $c > 1$, then $\tilde{C}$ winds around 1, whence $K_{N,\gamma^+}(x'cN, x'cN + l) = 0$.

In the case $|x' - c| = 2$, $A(z)$ has double real critical points and the contours should be deformed as shown in Figure 8. This case can be analyzed similarly by noting that the contribution from the neighborhood of the double critical point is negligible if contours are deformed as shown. 

3.3. **Depoissonization and local statistics of Schur–Weyl measures in the bulk.**

3.3.1. **Depoissonization.** A lemma proven by Borodin, Okounkov and Olshanski [BOO00, Lemma 3.1] allows us to pass from asymptotic properties of the poissonized measures to analogous properties of the original measures. We
Figure 8. Deformation of contours at the transition points. In the left figure contours do not cross. In the right figure one contour passes over the other. The shaded region corresponds to $\Re(A(z) - A(z^+)) < 0$. The solid red (right) and blue (left) contours are the original contours. The dotted red and blue contours are the deformed contours and both are linear near the double critical point.

present a modified version of the Depoissonization Lemma, which appeared in [Buf10].

Lemma 3.4 (Corollary 3.3 in [Buf10]). [Depsionization Lemma] Let $0 < \alpha < \frac{1}{4}$ and let $\{f_n\}$ be a sequence of entire functions

$$f_n(z) = e^{-z} \sum_{k=0}^{\infty} f_{nk} \frac{z^k}{k!}, \quad n = 1, 2, \ldots$$

Let $\tilde{C} > 0$, and let $a_n$ be a sequence of positive numbers satisfying $|a_n| \leq \tilde{C}$. If there exist constants $C_1, C_2, g_1, g_2 > 0$ and $f_\infty$ such that

$$\max_{|z|=n} |f_n(z)| \leq C_1 e^{g_1 \sqrt{n}}$$

and

$$\max_{|z-n|<n^{1-\alpha}} \frac{|f_n(z) - f_\infty|}{e^{g_2 |z-n|/\sqrt{n}}} \leq C_2 a_n,$$

then there exists a constant $C$ depending only on $C_1, C_2, g_1, g_2$ and $\tilde{C}$, such that for all $n > 0$ we have

$$|f_{nn} - f_\infty| \leq C a_n.$$

3.3.2. Depoissonization of $\mathbb{P}_N^{+,0}$. For $\varepsilon \geq 0$ denote

$$\mathcal{I}_N(\varepsilon) = \left\{ k \in \mathbb{Z} : \left| \frac{k}{cN} - c \right| \leq 2 - \varepsilon \right\},$$
and for $\delta > 0$ and $K > 0$ denote

$$I^+_N(K, \delta) = \left\{ k \in \mathbb{Z} : \left| \frac{k}{cN} - c \right| \leq 2 + KN^{\delta - 1} \right\}.$$

**Lemma 3.5.** There exist constants $C_1, C_2 > 0$ such that

$$\max_{|\gamma| = c^2 N} |K_{N, \gamma^+}(x, y)| \leq C_1 e^{C_2 N} \left( \frac{3}{2} \right)^{y-x}$$

for all $x$ and $y$ such that $\frac{x}{cN}, \frac{y}{cN} > -\frac{1}{c}$.

**Note:** Henceforth, whenever studying the kernel $K_{N, \gamma^+}$ and not the measure $\mathbb{P}^{\gamma^+, 0}_N$, we will allow $\gamma^+$ to be a complex parameter. In particular, this will be the case in depoissonization lemmas.

**Proof.** Let $\tilde{\gamma} = \frac{2}{c^2 N}$ and $l = y - x$. Using the contour–integral estimation result which states that for a continuous function $f$ it holds that

$$\left| \int_C f(z) dz \right| \leq \max_{z \in C} |f(z)| l(C),$$

where $l(C)$ is the length of the contour $C$, we obtain from (7) that

$$|K_{N, \gamma^+}(x, x + l)| \leq r^2 e^{2N \max(\Re(\tilde{\gamma}(u^{-1} - w^{-1})))} \frac{r^x}{(1 + r)^{1+x+l}} \frac{(1 + r)^N}{r^N} \frac{1}{1 - 2r},$$

where the plus sign is chosen when $1 + x + l < 0$. Since $|\tilde{\gamma}| = 1$, $|u| = r$ and $|w| \geq 1 - r$, it follows that

$$|\tilde{\gamma}(u^{-1} - w^{-1})| \leq \frac{1}{r} + \frac{1}{1 - r},$$

whence

$$\max(\Re(\tilde{\gamma}(u^{-1} - w^{-1}))) \leq \frac{1}{r(1 - r)}.$$

Thus,

$$|K_{N, \gamma^+}(x, x + l)| \leq r^2 \frac{(1 - r)^{-1-l}}{1 - 2r} e^{N \left( \frac{1}{c} \ln(r) - \ln(1 \mp r) + \frac{\ln(1 + r) + \ln(1 + r)}{1 - r} \right)}.$$

Since the coefficient of $\frac{\ln}{N}$ is $\ln(r) - \ln(1 \mp r) < 0$ and $\frac{\ln}{N}$ is bounded below, taking $r = \frac{1}{3}$ completes the proof.

**Lemma 3.6.** For any $\delta_0 > \frac{1}{3}$ and any integer $l$ there exist constants $C_1 = C_1(\delta_0, l) > 0$ and $C_2 = C_2(\delta_0, l) > 0$ such that

$$\left| K_{N, \gamma^+}(x, x + l) - \left( \frac{c}{\sqrt{1 + \frac{\phi}{cN}}} \right)^{-l} S(l, \phi \frac{\phi}{cN}) \right| \leq \frac{C_1 e^{C_2 (\gamma^+ - c^2 N)}}{2cN - |x - c^2 N|}.$$
where 0 < \gamma < A_C\) contours
\begin{equation}
(16)
K_{S_1,S_2} = \frac{1}{(2\pi i)^2} \oint_{S_1} \oint_{S_2} e^{N(A(u) - A(z^+))} e^{\gamma u - 1} \frac{1}{u - w}.
\end{equation}

It follows from \([7]\) that
\[K_{N,\gamma}(x, x + l) = K_{[u] = r, [w-1] = r},\]
where 0 < r < \frac{1}{2}. It follows from the proof of Theorem 3.3 that
\[K_{N,\gamma}(x, x + l) - \frac{1}{(2\pi i)} \oint_{z^+} u^{-1-l} du = K_{C_u,C_w}.\]

Let \(e^{\frac{x}{cN}} - c = \pm (2 - pN^{\delta - 1})\) for some \(p > 0\). From (10) and (11) we obtain
\begin{equation}
z^+ = \frac{c}{c \pm 1} + i \frac{c}{2(c \pm 1)^2} + O\left(N^{\delta - 1}\right),
\end{equation}
\begin{equation}
A''(z^+) = \mp i \frac{2(c \pm 1)^3 \sqrt{pN^{\frac{\delta - 1}{2}}}}{c} + O\left(N^{\delta - 1}\right),
\end{equation}
and
\begin{equation}
A'''(z^+) = \mp \frac{6(c \mp 2)(c \pm 1)^4 \sqrt{pN^{\frac{\delta - 1}{2}}}}{c^2} + O\left(N^{\delta - 1}\right).
\end{equation}

Since \(A'(z^+) = 0\), Taylor’s theorem implies
\[A(z^+ + e^{\xi t}) - A(z^+) = \frac{1}{2}(e^{\xi t})^2 A''(z^+) + \frac{(e^{\xi t})^3}{3!} A'''(z^+) + \frac{(e^{\xi t})^4}{4!} R_3(z^+ + e^{\xi t}),\]
where
\[R_3(u) = \frac{1}{2\pi i} \oint_{z^+} \frac{A(z)}{(z - z^+)^4(z - u)} dz,
\]
and the last integration is over a closed contour that contains both \(z^+\) and \(u\).

We can assume that the contours \(C_u\) and \(C_w\) are linear near the critical points \(z^\pm\), i.e. that there exist \(\xi, \psi \in (0, \frac{\pi}{2}) \cup (\frac{\pi}{2}, \pi)\) and \(t_0 > 0\) such that the contours \(C_u\) and \(C_w\) coincide respectively with \(z^\pm + e^{i\xi t}\) and \(z^\pm + e^{i\psi t}\), when \(|t| < t_0, t \in \mathbb{R}\). We have
\[\Re(A(z^+ + e^{i\xi t}) - A(z^+)) < 0 < \Re(A(z^+ + e^{i\psi t}) - A(z^+))\]
for all $0 < |t| < t_0$, $t \in \mathbb{R}$. Let $\beta$ be a constant such that $\frac{1}{3} < \beta < \frac{\delta_0 + 1}{4}$. Since $\Im(z^+) > N^{-\beta}$, we can divide the contour $C_u$ into three sections as follows:

$$C_{u,\pm} = z^\pm + e^{\pm \xi t} \text{ when } |t| < N^{-\beta}$$

and

$$C'_u = C_u \setminus (C_{u,+} \cup C_{u,-}).$$

Similarly, divide $C_w$ into three sections $C_{w,\pm}$ and $C'_w$ (see Figure 9). We estimate the contribution of each section separately. We will present the proofs of the following two estimates:

$$|K_{C'_u,C_w}| < C_1 e^{C_2 |\tilde{\gamma}|}$$

(21)

$$|K_{C_{u,+},C_{w,+}}| < C_1 e^{C_2 |\tilde{\gamma}|}$$

(22)

Estimates for the other sections can be obtained completely similarly.

We start with proving (21). Since the leading term of $A''(z^+)$ is of order $N^{\frac{\delta_0}{2}}$, $\xi \neq \frac{\pi}{2}$ and $R_3(u)$ is bounded in a neighborhood of $z^+$, there exists $D_1 \in (0, t_0)$ such that

$$\Re(A(u) - A(z^+)) \leq \begin{cases} 
-D_2 \sqrt{p} N^{\frac{\delta_0}{2} - 1} t^2, & u = z^\pm + e^{\pm \xi t} \text{ and } |t| \leq D_1 \\
-D_3, & u \in C'_u \cap \{u : |u - z^\pm| > D_1\}
\end{cases}$$

for some positive constants $D_2$ and $D_3$.

Since $|u|$ and $|w|$ are bounded away from zero and are bounded above along the contours $C_u$ and $C_w$, it follows that

$$\left|\frac{1}{u^{d+1} e^{\tilde{\gamma} u^{-1}}} \right| \leq C_1 e^{C_2 \tilde{\gamma}}.$$
Since $|u - w|^{-1} < N^\beta$ along the contours $C'_u$ and $C_w$, and $|e^{N(A(w) - A(z^+))}| > 1$ for all $w \in C_w$, we obtain
\begin{equation}
|K_{C'_u \cap \{u:|u-z^+|>D_1\}, C_w}| \leq C_1 N^\beta e^{C_2N} e^{-N^\beta N}.
\end{equation}
For the remaining part of the contour $C'_u$, we obtain
\begin{equation}
|K_{C'_u \cap \{u:|u-z^+|<D_1\}, C_w}| \leq C_1 e^{C_2N} N^\beta \int_{N^{-\beta}}^{D_1} e^{-D_2 \sqrt{pN}^{\frac{\beta+1}{2}}} t^2 dt.
\end{equation}
Making the change of variable $t' = \sqrt{D_2 \sqrt{pN}^{\frac{\beta+1}{2}}} t$, we obtain
\begin{equation}
\int_{N^{-\beta}}^{D_1} e^{-D_2 \sqrt{pN}^{\frac{\beta+1}{2}}} t^2 dt = \frac{N^\beta}{\sqrt{D_2} \sqrt{pN}^{\frac{\beta+1}{2}}} \int_{\sqrt{D_2} \sqrt{pN}^{\frac{\beta+1}{2}} N^{-\beta}}^{\sqrt{D_2} \sqrt{pN}^{\frac{\beta+1}{2}}} e^{-t^2} dt'
< \frac{1}{D_2 \sqrt{pN}^{\frac{\beta+1}{2} - \beta}} e^{-D_2 \sqrt{pN}^{\frac{\beta+1}{2} - 2\beta}}.
\end{equation}
Since $\beta < \frac{5+1}{4}$, combining (23), (24) and (25) we obtain (21).

We now move on to proving (22). We will consider two cases: when $|\tilde{\gamma}|$ is large and when it is small. Let $\zeta \in (0, \beta)$ and suppose $|\tilde{\gamma}| < N^\zeta$.

Since $A'(z^+) = 0$, we obtain
\begin{equation}
A(z^+ + e^{i\xi} t) - A(z^+) = \frac{1}{2} e^{i2\xi} A''(z^+) t^2 + t^3 \left( \frac{1}{6} e^{i3\xi} A'''(z^+) + O(t) \right).
\end{equation}
Since $\beta > \frac{1}{3}$, it follows that $Nt^3 = o(1)$, whence
\begin{equation}
\frac{e^{N^3 t^3} \left( \frac{1}{6} e^{i3\xi} A'''(z^+) + O(t) \right)}{e^{N^3 t^3} \left( \frac{1}{6} e^{i3\xi} A'''(z^+) + O(s) \right)} = 1 + O(|t|^3 + |s|^3)N.
\end{equation}
Since $|\tilde{\gamma}| < N^{\zeta - \beta}$ and $\zeta - \beta < 0$, we obtain
\begin{equation}
\frac{e^{\gamma(z^++e^{i\xi}t)^{-1}}}{e^{\gamma(z^++e^{i\psi}s)^{-1}}} = \frac{e^{\gamma(z^+-1)+O(|\tilde{\gamma}|)}}{e^{\gamma(z^+-1)+O(|\tilde{\gamma}|)}} = 1 + |\tilde{\gamma}|O(|t| + |s|).
\end{equation}
Define
\[\mathfrak{A}(t, s) = \frac{e^{N^\frac{1}{2} e^{i2\xi} A''(z^+) t^2}}{e^{N^\frac{1}{2} e^{i2\psi} A''(z^+) s^2}}.\]
Since the function
\[\mathfrak{A}(t, s) \frac{1}{t - e^{i(\psi - \xi)} s}\]
is an odd function, it follows that
\begin{equation}
\int_{-N^{-\beta}}^{N^{-\beta}} \int_{-N^{-\beta}}^{N^{-\beta}} \mathfrak{A}(t, s) \frac{dt \, ds}{t - e^{i(\psi - \xi)} s} = 0.
\end{equation}
Using (20), (26), (27), (28) and (29), and noting that
\[
\frac{1}{(z^+ + e^{i\psi} s)^{t+1}} = \frac{1}{(z^+)^{t+1}} + O(s),
\]
rewrite (16) as
\[
K_{C_u,C_w} = \int_{-N^{-\beta}}^{N^{-\beta}} \int_{-N^{-\beta}}^{N^{-\beta}} A(t, s) \times (O(|t^3 + s^3| N + |\gamma| O(|t| + |s|) + O(|s|)) \frac{dt \, ds}{t - e^{i(\psi - \xi)} s}.
\]

Making the change of variable
\[
t' = p^\frac{1}{2} N^{\frac{3}{4} + \frac{1}{4}} t, \quad s' = p^\frac{1}{2} N^{\frac{3}{4} + \frac{1}{4}} s,
\]
and using (18) we obtain
\[
|K_{C_u,C_w}| \leq C_1 e^{C_2 |\gamma|} \int_{-N^{-\beta}}^{N^{-\beta}} \int_{-N^{-\beta}}^{N^{-\beta}} A(t, s) \frac{dt \, ds}{t - e^{i(\psi - \xi)} s},
\]
where \(D_4\) is a positive constant. Since the remaining integral is \(O(N^{-\frac{3}{2} + \frac{1}{2}} + |\gamma|)\), we obtain
\[
|K_{C_u,C_w}| \leq \frac{C_1}{p N^{\delta}} e^{C_1 |\gamma|}.
\]
This completes the proof of (22) when \(|\gamma| < N^\xi\).

The case \(|\gamma| > N^\xi\) is much simpler. From (16) it follows that
\[
|K_{C_u,C_w}| \leq C_1 e^{C_2 |\gamma|} \int_{-N^{-\beta}}^{N^{-\beta}} \int_{-N^{-\beta}}^{N^{-\beta}} |A(t, s)| \frac{dt \, ds}{|t - e^{i(\psi - \xi)} s|}.
\]

Making the change of variable (30) it is easy to see that the remaining integral is \(O(1)\). Since \(|\gamma| > N^\xi\), (22) follows from (31).

\[\square\]

**Proposition 3.7** (Local statistics of \(P_{N}^{\eta}\) in the bulk). For any \(\varepsilon > 0\) and any integer \(L > 0\), there exists a positive constant \(C = C(\varepsilon, L)\) such that for all \(x \in I_N^\varepsilon\), all integer vectors \(l\) satisfying \(|l| \leq L\), all \(N \in \mathbb{N}\) and \(n = \lfloor c^2 N^2 \rfloor\), we have
\[
\left| \mathbb{E}_{P_N}^{\eta}(c_{x+l}) - \mathbb{E}_{S(x)}^{\eta}(c_l) \right| \leq \frac{C(\varepsilon, L)}{N}.
\]
Proof. This follows by applying the depoissonization Lemma 3.4 to Theorem 3.3. Lemmas 3.5 and 3.6 show that the necessary conditions for Lemma 3.4 to apply are satisfied.

3.4. Statistics near edges. We now prove that the probability of Young diagrams which extend beyond the limit shape at either edge by a distance more than $N^\delta$ with $\delta > \frac{1}{3}$ are exponentially small. We will need the following lemma, which gives an estimate for $K_{N,\gamma^+}(x,x)$ near the edges.

Lemma 3.8. For any $\delta_0 > \frac{1}{3}$ there exist constants $C_1, C_2, C_3 > 0$ such that for all $\delta \in [\delta_0, 1)$, for all $\gamma^+$, for all $N \in \mathbb{N}$, and $x \notin \mathbb{T}_N^+(1,\delta)$, $x > -N$, we have

\begin{equation}
|1 - K_{N,\gamma^+}(x,x)| \leq C_1 e^{-C_2 N^{\frac{3\delta}{2}} - \frac{1}{2} e^{C_3|\gamma^+-c^2N|}}, \text{ if } 0 < c < 1 \text{ and } x < 0,
\end{equation}

and

\begin{equation}
|K_{N,\gamma^+}(x,x)| \leq C_1 e^{-C_2 N^{\frac{3\delta}{2}} - \frac{1}{2} e^{C_3|\gamma^+-c^2N|}}, \text{ if } 1 < c \text{ or } x > 0.
\end{equation}

Proof. As before, we let $\tilde{\gamma} = \gamma^+ - c^2 N$ and drop the indices for $A$, $z^\pm$ and $\phi$ to simplify notation. The indices in this proof are $\frac{x}{cN}$.

Suppose $0 < c < 1$ and $x < 0$. Let $x = (c-2)cN - pcN^\delta$, $p > 0$. It follows from (10) that $A(z)$ has two distinct real critical points. Let $z^-$ be the smaller critical point. Similarly to (17) we obtain

$$z^- = \frac{c}{c-1} - \frac{c\sqrt{p}}{(1-c)^2} N^{\delta-1} + O(N^{\delta-1}).$$

If we deform the contours of integration of $K_{N,\gamma^+}(x,x)$ according to the saddle point method, one contour completely moves over the other. Thus, the residues we pick up total to 1 and we have

$$K_{N,\gamma^+}(x,x) - 1 = \left| \frac{1}{2\pi i} \oint_{C_u} \oint_{C_w} e^{\frac{N(A(u)-A(z^-))}{w}} e^{\frac{5\gamma u-1}{w}} \frac{1}{u-w} \right|,$$

where the contours $C_u$ and $C_w$ are as in the left part of Figure 10. Without changing the integral, the contour $C_w$ can be further deformed into two closed contours $C^o_w$ and $C^i_w$ as in the right part of Figure 10. The outer contour $C^o_w$ can be moved so that there exists a constant $C_2 > 0$ such that $\Re(A(w) - A(z^-)) > C_2$ for all $w$ along this contour. Since $u$ and $w$ are bounded away from 0 and 1, we obtain

$$\left| \frac{1}{2\pi i} \oint_{C_u} \oint_{C^o_w} e^{\frac{N(A(u)-A(z^-))}{w}} e^{\frac{5\gamma u-1}{w}} \frac{1}{u-w} \right| \leq C_1 e^{-C_2 N e^{C_3|\tilde{\gamma}|}},$$

for some constants $C_1, C_3 > 0$. 

Figure 10. Deformation of contours near the left edge when $0 < c < 1$. $A(z)$ has two distinct real critical points. The shaded region corresponds to $\Re(A(z) - A(z^-)) < 0$. The solid red(right) and blue(left) contours are the original contours. The dotted red and blue contours are the deformed contours. The shaded region is bounded and the dotted red contour loops around it (not visible from the figures).

Since $z^-$ is a critical point of $A(z)$, it follows from Taylor’s theorem that

$$A(z^- + t) - A(z^-) = \frac{1}{2} t^2 A''(z^-) + \frac{1}{6} t^3 A'''(z^-) + O(t^4).$$

Similarly to (18) and (19) we obtain

$$A''(z^-) = -\frac{2(c - 1)^3}{c} \sqrt{p} N^{\frac{\delta - 1}{2}} + O(N^{\delta - 1}) > 0$$

and

$$A'''(z^-) = 2\left(\frac{c - 1)^5}{c^2} + \frac{6(c + 2)(c - 1)^4}{c^2}\right) \sqrt{p} N^{\frac{\delta - 1}{2}} + O(N^{\delta - 1}),$$

which imply that there exist constants $D_1, D_2 > 0$, depending only on $c$ and $p$, such that for $t_0 = D_1 N^{\frac{\delta - 1}{2}}$ we have

$$A(z^- + t_0) - A(z^-) = D_2 t_0^2 N^{\frac{\delta - 1}{2}} + O(N^{\delta - 1})$$

and

$$A(z^- + t) - A(z^-) > 0 \quad \text{for all } t \in (0, t_0].$$

Thus, the inner contour $C^i_w$ can be chosen so that

$$\Re(A(w) - A(z^-)) = D_2 t_0^2 N^{\frac{\delta - 1}{2}} \quad \text{for all } w \in C^i_w,$$
and \(|u - w| \geq D_3 t_0 \) for some constant \(D_3\) and all \(u \in C_u, w \in C_w\). Hence, there are constants \(C_1, C_2, C'_2, C_3 > 0\) such that
\[
\left| \frac{1}{(2\pi i)^2} \int_{C_u} \int_{C_w} \frac{e^{N(A(u) - A(z^{-1}))}}{e^{N(A(w) - A(z^{-1}))}} e^{\xi w^{-1}} \frac{1}{w - w} \right| 
\leq C_1 e^{-N \left( C_2 t_0^2 N^{-\frac{3}{2}} \right)} e^{C_3 |\xi|} \leq C_1 e^{-C_2 N^{\frac{3}{2}} - \frac{1}{2} e^{C_3 |\xi|}}.
\]
This completes the proof of (32). The argument for (33) is similar. 

\[\square\]

**Proposition 3.9.** Let \(l(\lambda)\) denote the length of \(\lambda\), i.e. the number of nonzero entries in \(\lambda\), or equivalently the number of rows in its diagram. For any \(\delta_0 > \frac{1}{3}\) there exist constants \(C_1, C_2 > 0\) such that for all \(\delta \in [\delta_0, 1]\), for all \(N \in \mathbb{N}\) and for \(n = \lfloor c^2 N^2 \rfloor\) we have
\[
\mathbb{P}_N^n \left( \{ \lambda : l(\lambda) > (2 - c)cn + N^{\delta} \} \right) \leq C_1 e^{-C_2 N^{\frac{3}{2}} - \frac{1}{2}}, \quad \text{if } 0 < c < 1,
\]
\[
\mathbb{P}_N^n \left( \{ \lambda : \lambda_N < N + (c - 2)cn - N^{\delta} \} \right) \leq C_1 e^{-C_2 N^{\frac{3}{2}} - \frac{1}{2}}, \quad \text{if } 1 < c,
\]
and
\[
\mathbb{P}_N^n \left( \{ \lambda : \lambda_1 > (2 + c)cn + N^{\delta} \} \right) \leq C_1 e^{-C_2 N^{\frac{3}{2}} - \frac{1}{2}}, \quad \text{if } 0 < c.
\]

**Proof.** Throughout the proof \(C_1\) and \(C_2\) denote arbitrary constants that depend only on \(\delta_0\). Since \(l(\lambda) > (2 - c)cn + N^{\delta}\) implies that there exists \(x \in [-N, (c - 2)cn - N^{\delta}]\) such that \(c_x(\lambda) = 0\), we obtain
\[
\mathbb{P}_N^n \left( \{ \lambda : l(\lambda) > (2 - c)cn + N^{\delta} \} \right) \leq \sum_{x \in [-N, (c - 2)cn - N^{\delta}]} \left( 1 - \mathbb{E}_{\mathbb{P}_N^n}(c_x) \right).
\]
When \(0 < c < 1\) and \(x \in [-N, (c - 2)cn - N^{\delta}]\), by Lemma 3.8 we obtain
\[
|1 - \mathbb{E}_{\mathbb{P}_N^n}(c_x)| = |1 - K_{N, \gamma^+}(x, x)| \leq C_1 e^{-C_2 N^{\frac{3}{2}} - \frac{1}{2} e^{C_3 \gamma^+ - c^2 N}}.
\]
Depoissonizing by Lemma 3.4 we obtain
\[
|1 - \mathbb{E}_{\mathbb{P}_N^n}(c_x)| \leq C_1 e^{-C_2 N^{\frac{3}{2}} - \frac{1}{2}}.
\]
This implies the first statement of the proposition since the index set in the sum in (34) is of order \(N\).

To prove the second statement, notice that
\[
\mathbb{P}_N^n \left( \{ \lambda : \lambda_N < N + (c - 2)cn - N^{\delta} \} \right) \leq \sum_{x \in [-N, (c - 2)cn - N^{\delta}]} \mathbb{E}_{\mathbb{P}_N^n}(c_x)
\]
and proceed as above.

The last statement of the proposition can be proven in a similar way.
Note: The last statement of Proposition 3.9 also follows immediately from Theorem 1.7 in [Joh01], where it is proven that after appropriate scaling the local fluctuations of the longest row are characterized by the Tracy-Widom distribution.

Let $L_\lambda(x)$ be the boundary of the rotated Young diagram $\lambda$ when it is scaled so that the cells have diagonal 2. We have $L_\lambda(x) = \sqrt{n}L_\lambda\left(\frac{x}{\sqrt{n}}\right)$. For $\delta > 0$ and $K > 0$ denote

$$\mathbb{Y}^n_N(K,\delta) = \{\lambda \in \mathbb{Y}^n_N : \text{supp}\ |L_\lambda(x) - |x|| \subset \mathcal{I}^+_N(K,\delta)\}.$$ 

Figure 11 illustrates the restrictions put on the Young diagrams in the set $\mathbb{Y}^n_N(K,\delta)$.

**Corollary 3.10.** For any $\delta_0 > \frac{1}{3}$ there exist constants $C_1, C_2 > 0$ such that for all $\delta \in [\delta_0, 1)$, for all $N \in \mathbb{N}$ and for $n = \lfloor c^2N^2 \rfloor$ we have

$$\mathbb{P}^n_N(\mathbb{Y}^n_N \setminus \mathbb{Y}^n_N(K,\delta)) \leq C_1e^{-C_2N^{\frac{2c^2-1}{2}}}, \text{ if } 0 < c < 1,$$

**Proof.** This is essentially a reformulation of Proposition 3.9. \hfill \Box
4. Estimates of the Correlation Kernel

We need to estimate the decay of correlations. For this purpose a different representation of the correlation kernel is useful. In this section we obtain this representation and use it to obtain various estimates for the correlation kernel.

Define the functions

\[ K^+_{x,N}(\gamma) = \frac{1}{2\pi i} \oint e^{\gamma + u^{-1}} (1 - u)^N u^x \, du \]

where integration is over any closed counter-clockwise contour winding once around 0, and

\[ K^-_{y,N}(\gamma) = \frac{1}{2\pi i} \oint e^{-\gamma + w^{-1}} (1 - w)^{-N} w^{-y} \, dw \]

where integration is over any closed counter-clockwise contour winding once around 1 and not containing 0.

**Lemma 4.1.** If \( x \neq y \), then

\[ K_{N,\gamma+}(x,y) = \frac{N K^+_{x,N-1}(\gamma) K^+_{y+1,N+1}(\gamma) - \gamma + K^+_{x-1,N}(\gamma) K^-_{y+2,N}(\gamma)}{x - y} \]

**Proof.** The main idea of the proof is to integrate formula (7) by parts (the idea was used by A. Okounkov to obtain a similar formula for the Bessel kernel [Oko02]).

In general, for functions \( f(u,w) \) and \( g(u,w) \) which are differentiable on simple closed contours \( C_u \) and \( C_w \) integration by parts gives

\[
\oint_{C_u} \oint_{C_w} f \left( u \frac{\partial}{\partial u} + w \frac{\partial}{\partial w} \right) g \, dw \, du
\]

\[
= \oint_{C_u} \oint_{C_w} f u \frac{\partial}{\partial u} g \, dw \, du + \oint_{C_u} \oint_{C_w} f w \frac{\partial}{\partial w} g \, dw \, du
\]

\[
= - \oint_{C_u} \oint_{C_w} g \left( u \frac{\partial}{\partial u} + 1 \right) f \, dw \, du - \oint_{C_u} \oint_{C_w} g \left( w \frac{\partial}{\partial w} + 1 \right) f \, dw \, du
\]

\[
= - \oint_{C_u} \oint_{C_w} g \left( u \frac{\partial}{\partial u} + w \frac{\partial}{\partial w} + 2 \right) f \, dw \, du.
\]

Since

\[ u^x w^{-y-1} = \left( u \frac{\partial}{\partial u} + w \frac{\partial}{\partial w} + 1 \right) \frac{u^x w^{-y-1}}{x - y}, \]
applying the integration by parts calculation above to (7) we obtain

\[ K_{N,\gamma} (x, y) = -\frac{1}{(2\pi i)^2} \int_{C_u} \int_{C_w} \frac{u^x w^{-y-1}}{x-y} \times \left( u \frac{\partial}{\partial u} + w \frac{\partial}{\partial w} + 1 \right) e^{\gamma^+ (u^{-1}w^{-1}) \frac{(1-u)^N}{(1-w)^N}} \ du \ dw. \]

It follows from

\[ \left( u \frac{\partial}{\partial u} + w \frac{\partial}{\partial w} + 1 \right) e^{\gamma^+ (u^{-1}w^{-1}) \frac{(1-u)^N}{(1-w)^N}} = e^{\gamma^+ (u^{-1}w^{-1}) \frac{(1-u)^N}{(1-w)^N}} \left( \frac{\gamma^+}{uw} - \frac{N}{(1-u)(1-w)} \right) \]

that the integrals with respect to \( u \) and \( w \) can be separated. Carrying this out we obtain (35).

4.1. Estimates of \( K_{x,N}^{\pm}(\gamma^+) \) for various values of \( x \).

**Lemma 4.2.** For any \( \delta_0 > \frac{1}{3} \) there exist constants \( C_1 = C_1(\delta_0) > 0 \) and \( C_2 = C_2(\delta_0) > 0 \) such that

\[ |K_{x,N}^{\pm}(\gamma^+)| \leq C_1 e^{\pm N\Re A_{\pm N}(z^+) \frac{\gamma^+ - c^2 N}{N^{\frac{1}{4}}}} \]

for all \( \delta \in [\delta_0, 1) \), all \( x \in \mathcal{I}_N(1, \delta) \), all \( \gamma^+ \) and all \( N \in \mathbb{N} \).

**Proof.** We present the proof of the result for \( K_{x,N}^{+}(\gamma^+) \). The proof for \( K_{x,N}^{-}(\gamma^+) \) is completely identical.

Throughout the proof \( C_1 \) and \( C_2 \) will denote arbitrary constants that depend only on \( \delta_0 \). We will use the same notation as in the proof of Lemma 3.6. In particular \( \tilde{\gamma} = \gamma^+ - c^2 N \), \( A(u) = A_{\pm N}(u) \), \( z^\pm = z^\pm_{\pm N} \), the contour of integration is deformed so that it goes through \( z^\pm \) and has the property that for all \( u \) on the deformed contour \( \Re (A(u) - A(z^+)) \leq 0 \) and the deformed contour \( C_u \) is divided into three parts as in (20). Consider

\[ K_{x,N}^{+}(\gamma^+) e^{-NA(z^+)} = \frac{1}{2\pi i} \int_{C_u} e^{N(A(u) - A(z^+))} e^{\tilde{\gamma} u^{-1}} \ du. \]

Let \( \frac{x}{N} - c = \pm (2 - pN^{\delta-1}) \) for some \( p > 0 \). Arguments similar to those in the proof of Lemma 3.6 show that the contribution of the large contour \( C_u' \) is
obtain which completes the proof when \( x > \delta \) for all \( x \).

For any Lemma 4.3. Of course, the contribution from \( K \) for some positive constant \( D \). Making the change of variable \( t' = N^{\frac{d+1}{4}} t \) we obtain

\[
\left| \frac{1}{2\pi i} \oint_{C_{u,+}} e^{N(A(u)-A(z^{\pm}))} e^{\gamma u^{-1}} \, du \right| \leq C_1 e^{C_2[5]} \int_{-N^{-\beta}}^{N^{-\beta}} e^{N R(A(z^{\pm}+\xi t)-A(z^{\pm}))} \, dt \\
\leq C_1 e^{C_2[5]} \int_{-N^{-\beta}}^{N^{-\beta}} e^{-D\sqrt{\pi}N^{\frac{d+1}{4}} \xi^2} \, dt
\]

for some positive constant \( D \). Making the change of variable \( t' = N^{\frac{d+1}{4}} t \) we obtain

\[
\left| \frac{1}{2\pi i} \oint_{C_{u,+}} e^{N(A(u)-A(z^{\pm}))} e^{\gamma u^{-1}} \, du \right| \leq C_1 \frac{e^{C_2[5]} N^{\frac{d+1}{4} - \beta}}{\sqrt{\pi}} \int_{-N^{-\frac{d+1}{4} - \beta}}^{N^{-\frac{d+1}{4} - \beta}} e^{-D\sqrt{\pi}N^{\frac{d+1}{4}} \xi^2} \, dt' \leq C_1 \frac{e^{C_2[5]} N^{\frac{d+1}{4}}}{\sqrt{\pi}}.
\]

Of course, the contribution from \( C_{u,-} \) is of the same order. \( \square \)

**Lemma 4.3.** For any \( \delta_0 > \frac{1}{3} \) there exist constants \( C_1 = C_1(\delta_0) > 0 \) and \( C_2 = C_2(\delta_0) > 0 \) such that

\[
\left| K_{x+1,N}^\pm(\gamma^+) - \operatorname{sign}(x)cK_{x,N+1}^\pm(\gamma^+) \right| \leq C_1 e^{\pm N \frac{R A \frac{e^{C_2[1]}(z^{\pm})}{c^{\frac{1}{N}}} e^{C_2[1]c^{\gamma^+ - \epsilon^2 N}}}{N^{\frac{2}{3} - \delta}}
\]

for all \( \delta \in [\delta_0, 1) \), all \( x \in \mathcal{I}_N(1, \delta) \), all \( \gamma^+ \) and all \( N \in \mathbb{N} \).

**Proof.** We present the proof of the result for \( K_{x,N}^+(\gamma^+) \). The proof for \( K_{x,N}^-(\gamma^+) \) is completely identical.

In this proof the indices of \( A(u) \) and \( z^+ \) are \( \frac{x}{c^N} \). The proof is similar to the proof of Lemma 4.2. Suppose \( \frac{x}{c^N} - c = (2 - pN^{d-1}) > 0 \). We have

\[
(K_{x+1,N}^+(\gamma^+) - cK_{x,N+1}^+(\gamma^+)) e^{-NA(z^+)}
\]

\[
= \frac{1}{2\pi i} \oint_C e^{N(A(u)-A(z^+))} e^{\gamma u^{-1}} (u - c(1-u)) \, du.
\]

The main contribution comes from the sections of the contour near \( z^\pm \). If \( u = z^+ + e^{i\xi} t \), then from (17) we obtain

\[
|u - c(1-u)| = (c+1) \left| z^+ + e^{i\xi} t - \frac{c}{c+1} \right| \leq D_1 N^{\frac{d-1}{4}} + D_2 t
\]

for some positive constants \( D_1, D_2 \). Proceeding as in Lemma 4.2 we obtain

\[
\left| K_{x+1,N}^+(\gamma^+) - cK_{x,N+1}^+(\gamma^+) \right|
\]

\[
\leq C_1 e^{N \frac{R A \frac{e^{C_2[1]}(z^{\pm})}{c^{\frac{1}{N}}} e^{C_2[1]c^{\gamma^+ - \epsilon^2 N}}}{N^{\frac{2}{3} - \delta} + \frac{D_1 N^{\frac{d-1}{4}}}{c^{\frac{1}{N}}} + \frac{D_2}{N^{\frac{d-1}{4}}}}},
\]

which completes the proof when \( x > 0 \).
When \( x < 0 \), instead of \( u - c(1 - u) \) we have
\[
|u + c(1 - u)| = |c - 1| \left| z^+ + e^{i\xi}t - \frac{c}{c - 1} \right|,
\]
and the rest follows as above, since in this case it follows from (17) that the leading term of \( z^+ \) is \( \frac{c}{c - 1} \).

\[\square\]

**Lemma 4.4.** There exist constants \( C_1 > 0 \) and \( C_2 > 0 \) such that
\[
\left| K_{x,N}^\pm(\gamma^+) \right| \leq C_1 e^{\pm N \text{Re} \left( \frac{1}{cN} \right)} (z^+) e^{C_2 |\gamma^+ - c^2 N|} \frac{1}{N^{\frac{1}{2}}}
\]
for all \( x \), all \( \gamma^+ \) and all \( N \in \mathbb{N} \).

**Proof.** We present the proof of the result for \( K_{x,N}^+(\gamma^+) \). As before, we drop the indices of \( A(z) \) and \( z^+ \), which are \( \frac{x}{cN} \) in this proof, and let \( \tilde{\gamma} = \gamma^+ - c^2 N \).

Let \( \left| \frac{x}{cN} - c \right| = 2 - pN^{\delta - 1}, \delta \geq 0 \).

Suppose \( p > 0 \). In this case \( A(z) \) has complex conjugate critical points. We deform the integration contour as contour \( C_u \) in Lemma [3.6], however with one difference: near the critical points we deform the contour to be piecewise linear with different slopes on each side of the critical points. More precisely, let \( \xi_{1,2} \in (0, \pi) \) and deform the integration contour so that it is given by \( z^\pm + e^{i\xi_1}t, t > 0 \) and \( z^\pm - e^{i\xi_2}t, t > 0 \) near the critical points \( z^\pm \). Choose \( \xi_{1,2} \) so that both \( \Re(e^{2i\xi}A'(z^+)) < 0 \) and \( \Re(e^{3i\xi}A''(z^+)) < 0 \). For example, when \( \frac{x}{cN} - c = 2 - pN^{\delta - 1} \), it follows from (18) and (19) that \( \frac{\pi}{2} < \xi_{1,2} < \frac{5\pi}{6} \).

We divide the contour into five sections: one away from the critical points and two linear sections near each critical point. That the contribution of the contour away from the critical points is exponentially small, can be seen as in Lemma [3.6]. The contribution of the linear sections near the critical points is of order
\[
B(N) = \int_0^\varepsilon e^{-N(D_1t^2 + D_2t^3)} e^{\tilde{\gamma} \Re \left( (z^\pm + e^{i\xi_{1,2}}t)^{-1} \right)} dt
\]
for some positive constants \( D_1 \) and \( D_2 \). We estimate \( B(N) \) as follows:
\[
B(N) \leq e^{C_2 \varepsilon} \int_0^\varepsilon e^{-D_2Nt^3} dt = e^{C_2 \varepsilon} \frac{N^{\frac{1}{2}}}{N^{\frac{3}{2}}} \int_0^\varepsilon e^{-D_2s^3} ds \leq C_1 e^{C_2 \varepsilon} \frac{N^{\frac{1}{2}}}{N^{\frac{3}{2}}}
\]

When \( p < 0 \), \( A(z) \) has two real critical points. We deform the integration contour as in Lemma [3.8] and proceed as above.

\[\square\]
Lemma 4.5. For any $\delta > \frac{1}{3}$ there exist constants $C_1 > 0$, $C_2 > 0$ and $C_3 > 0$ such that

$$\left| K_{x,N}^{\pm}(\gamma^+) \right| \leq C_1 e^{\pm N R^A \frac{a}{z^A}(z^+)} e^{-C_3 N \frac{\delta_0}{2} \frac{1}{2} e^{C_2 |\gamma^+ - c^2 N|}}$$

for all $x \notin I_N^+(1, \delta)$, $x > -N$, all $\gamma^+$ and all $N \in \mathbb{N}$.

**Proof.** For $K_{x,N}^-(\gamma^+)$ deform the integration contour as contour $C_w$ in Lemma 3.8 and estimate the contour integral as in Lemma 3.8. The only difference in obtaining the estimate for $K_{x,N}^+(\gamma^+)$ is that the contour should be deformed to pass through the larger of the two real critical points of $A_{\frac{x}{z^A}}(z)$. \qed

4.2. Several estimates of the correlation kernel. In this section we use the estimates of the functions $K_{x,N}^{\pm}$ obtained in the previous section to obtain estimates for the correlation kernel.

Lemma 4.6. For any $\varepsilon > 0$ there exist constants $C_1$ and $C_2$ such that

$$|K_{N,\gamma^+}(x,y)| \leq C_1 e^{C_2 |\gamma^+ - c^2 N|} e^{N R^A \frac{a}{z^A}(z^+)} e^{-A_{\frac{x}{z^A}}(z^+)}$$

for all $x, y \in I_N(\varepsilon)$, all $\gamma^+$ and all $N \in \mathbb{N}$.

**Proof.** When $x \neq y$ this follows from Lemmas 4.1 and 4.2. When $x = y$ the result follows from Lemma 3.6. \qed

Lemma 4.7. Let $K_1$ and $K_2$ be arbitrary positive constants, let $\frac{1}{3} < \delta_0 \leq \delta_1, \delta_2 \leq 1$, and let $x \in I_N^-(K_1, \delta_1)$, $y \in I_N^-(K_2, \delta_2)$. There exist constants $C_1, C_2 > 0$, which depend only on $K_1, K_2$ and $\delta_0$, such that for all $\gamma^+$ and for all $N \in \mathbb{N}$ the following hold. If $x$ and $y$ have the same sign, then

$$|K_{N,\gamma^+}(x,y)K_{N,\gamma^+}(y,x)| \leq C_1 e^{C_2 |\gamma^+ - c^2 N|} \frac{N^{\frac{|\delta_1 - \delta_2|}{2}}}{(1 + |x - y|)^2}.$$  

If $x$ and $y$ have opposite signs, then

$$|K_{N,\gamma^+}(x,y)K_{N,\gamma^+}(y,x)| \leq C_1 e^{C_2 |\gamma^+ - c^2 N|} \frac{N^{1 - \frac{\delta_1 + \delta_2}{2}}}{(1 + |x - y|)^2}.$$
Proof. If $x = y$, the result follows immediately from Lemma 3.6. If $x \neq y$ and they have the same sign, from Lemma 4.1 we obtain

\[
K_{N,\gamma^+}(x, y) = \frac{1}{x - y} \left( NK_{x,N-1}^+(\gamma^+) \left( K_{y+1,N-1}^+(\gamma^+) - \text{sign}(y) cK_{y+2,N}^-(\gamma^+) \right) + \text{sign}(y) N c \left( K_{x,N-1}^+(\gamma^+) - \text{sign}(x) cK_{x-1,N}^+(\gamma^+) \right) K_{y+2,N}^-(\gamma^+) \right).
\]

If $|\gamma^+ - c^2 N| < N^\frac{1}{2}$, applying Lemmas 4.2 and 4.3 we obtain (36). If $|\gamma^+ - c^2 N| > N^\frac{1}{2}$, applying the same lemmas we obtain

\[
|K_{N,\gamma^+}(x, y)K_{N,\gamma^+}(y, x)| \leq C_1 e^{C_2|\gamma^+ - c^2 N|} |\gamma^+ - c^2 N|^2 N^{\frac{5-2\delta_1-\delta_2}{2}} (1 + |x - y|)^2,
\]

which implies (36) with a larger $C_2$.

When $x$ and $y$ have opposite signs, (37) follows from Lemmas 4.1 and 4.2.

Remark 4.8. Notice that one of the sets $\mathcal{I}_N^-(K_1, \delta_1), \mathcal{I}_N^-(K_2, \delta_2)$ is contained in the other. If, for example, $\mathcal{I}_N^-(K_1, \delta_1) \subset \mathcal{I}_N^-(K_2, \delta_2)$, then both $x$ and $y$ are in $\mathcal{I}_N^-(K_2, \delta_2)$, whence (36) implies the better estimate

\[
|K_{N,\gamma^+}(x, y)K_{N,\gamma^+}(y, x)| \leq C_1 e^{C_2|\gamma^+ - c^2 N|} (1 + |x - y|)^2.
\]

Lemma 4.9. Let $K > 0$ and $\frac{1}{2} < \delta_0 \leq \delta_1 < 1$. There exist constants $C_1, C_2 > 0$, which depend only on $K$ and $\delta_0$, such that for all $\gamma^+$, for all $x \in \mathcal{I}_N^-(K_1, \delta_1)$, for all $y$ and for all $N \in \mathbb{N}$ we have

\[
|K_{N,\gamma^+}(x, y)K_{N,\gamma^+}(y, x)| \leq C_1 e^{C_2|\gamma^+ - c^2 N|} \frac{N^\frac{5-2\delta_1-\delta_0}{6}}{(1 + |x - y|)^2}.
\]

Proof. The lemma follows immediately from Lemmas 4.1, 4.2 and 4.4.

Lemma 4.10. Let $K_1$ and $K_2$ be arbitrary positive constants, let $\frac{1}{3} < \delta_0 \leq \delta_1 < 1$, $\frac{1}{3} \leq \delta_2$, and let $x \in \mathcal{I}_N^-(K_1, \delta_1), y \notin \mathcal{I}_N^+(K_2, \delta_2), y > -N$. There exist constants $C_1, C_2, C_3 > 0$, which depend only on $K_1, K_2$ and $\delta_0$, such that for all $\gamma^+$ and for all $N \in \mathbb{N}$ we have

\[
|K_{N,\gamma^+}(x, y)K_{N,\gamma^+}(y, x)| \leq C_1 e^{C_2|\gamma^+ - c^2 N|} \frac{e^{-C_3 N^{\frac{3\delta_0}{2} - \frac{1}{2}}}}{(1 + |x - y|)^2}.
\]
Proof. Lemmas \[4.4\] and \[4.5\] imply
\[
|K_{N,\gamma^+}(x, y)| \leq C_1 \frac{e^{C_2|\gamma^+ - c^2N|} e^{-C_3N \frac{\gamma^+}{x}}}{1 + |x - y|} e^{N \Re (A \frac{z^+}{xN} - A \frac{z^+}{yN})}
\]
while Lemmas \[4.4\] and \[4.5\] imply
\[
|K_{N,\gamma^+}(y, x)| \leq C_1 \frac{e^{C_2|\gamma^+ - c^2N|} e^{-C_3N \frac{\gamma^+}{x}}}{1 + |x - y|} e^{N \Re (A \frac{z^+}{yN} - A \frac{z^+}{xN})}
\]
Combining the two estimates completes the proof.

\[\square\]

4.3. Decay of correlations in the bulk. In this section we use the estimates of the correlation kernel obtained in the previous section to estimate the decay of correlations in the bulk.

Proposition 4.11. For any \(\varepsilon > 0\) and any integer \(L > 0\) there exist positive constants \(C_1 = C_1(\varepsilon, L)\) and \(C_2 = C_2(\varepsilon, L)\) such that
\[
\text{Cov}_{F_N^{\gamma^+}}(x, \tilde{l}; y, \tilde{m}) := \left|\mathbb{E}_{F_N^{\gamma^+}}(c_{x+\tilde{l}} c_{y+\tilde{m}}) - \mathbb{E}_{F_N^{\gamma^+}}(c_{x+i}) \mathbb{E}_{F_N^{\gamma^+}}(c_{y+i})\right| \\
\leq C_1 e^{C_2|\gamma^+ - c^2N|} \left(\frac{1}{1 + |x - y|}\right)^2
\]
for all \(x, y \in \mathcal{I}_N(\varepsilon)\), all integer vectors \(\tilde{l}\) and \(\tilde{m}\) satisfying \(|\tilde{l}|, |\tilde{m}| \leq L\), all \(\gamma^+\) and all \(N \in \mathbb{N}\).

Proof. It follows from Theorem 3.2 that \(\mathbb{E}_{F_N^{\gamma^+}}(c_{x+i} c_{y+i})\) is a determinant of the form
\[
\mathbb{E}_{F_N^{\gamma^+}}(c_{x+i} c_{y+i}) = \det A = \det \begin{pmatrix} B & C \\ D & E \end{pmatrix},
\]
where \(\mathbb{E}_{F_N^{\gamma^+}}(c_{x+i}) = \det B\) and \(\mathbb{E}_{F_N^{\gamma^+}}(c_{y+i}) = \det E\).

Thus, it follows that \(\text{Cov}_{F_N^{\gamma^+}}(x, \tilde{l}; y, \tilde{m})\) consists of terms in \(\det A\) which have at least one factor from each of \(C\) and \(D\). Since the terms in \(C\) and \(D\) are of the form \(K_{N,\gamma^+}(x + l_i, y + m_j)\), the proposition follows from Lemma 4.6

Note that the factors
\[
e^{N \Re (A \frac{z^+}{xN} - A \frac{z^+}{yN})}
\]
cancel out, since we are taking a determinant.

\[\square\]
Proposition 4.12. For any $\varepsilon > 0$ and any integer $L > 0$ there exists a positive constant $C = C(\varepsilon, L)$ such that

$$\left| \mathbb{E}_{P_N^\varepsilon}^\alpha(c_{x+\vec{l}} \cdot c_{y+\vec{m}}) - \mathbb{E}_{P_N^\varepsilon}^\alpha(c_{x+\vec{l}}) \mathbb{E}_{P_N^\varepsilon}^\alpha(c_{y+\vec{m}}) \right| \leq \frac{C}{\min\{N, (1 + |x-y|^2)\}}$$

for all $x, y \in I_N(\varepsilon)$, all integer vectors $\vec{l}$ and $\vec{m}$ satisfying $|\vec{l}|, |\vec{m}| \leq L$, all $N \in \mathbb{N}$ and $n = \lfloor c^2 N^2 \rfloor$.

Proof. If $x \in I_N(\varepsilon)$, then $2cN - |x - c^2 N|$ is of order $N$. Using Lemma 3.6 and Proposition 4.11, and noting that the terms $\left( \frac{c}{\sqrt{1+\frac{x}{n}}} \right)^{-l}$ in Lemma 3.6 cancel since we are taking determinants, we obtain

$$\left| \mathbb{E}_{P_N^\varepsilon}^\alpha(c_{x+\vec{l}} \cdot c_{y+\vec{m}}) - \mathbb{E}_{S(\frac{x}{N})}^\alpha(c_{x+\vec{l}}) \mathbb{E}_{S(\frac{y}{N})}^\alpha(c_{y+\vec{m}}) \right| \leq \frac{C_1 e^{C_2 |\gamma - c^2 N|}}{\min\{N, (1 + |x-y|^2)\}}.$$ 

Depoissonizing by Lemma 3.4 we obtain

$$\left| \mathbb{E}_{P_N}^\alpha(c_{x+\vec{l}} \cdot c_{y+\vec{m}}) - \mathbb{E}_{S(\frac{x}{N})}^\alpha(c_{x+\vec{l}}) \mathbb{E}_{S(\frac{y}{N})}^\alpha(c_{y+\vec{m}}) \right| \leq \frac{C}{\min\{N, (1 + |x-y|^2)\}}.$$ 

Applying Proposition 3.7 to this expression completes the proof.

5. Proof of Theorem 1.1

In this section we present the proof of the main theorem. We evaluate the limit of the terms in (2) separately.

Lemma 5.1. For any $\varepsilon > 0$ we have

$$\lim_{N \to \infty} \lim_{n \to \infty} \mathbb{P}_{N}^n \{ \lambda : |\hat{\rho}(\lambda)| < \varepsilon \} = 1,$$

where $\hat{\rho}(\lambda)$ is as in Proposition 2.2.

Proof. Let $c_k(\lambda)$ be the number of cells in $\lambda$ with content $k$. Notice that if $\lambda \in Y_N$, then $c_{k-N}(\lambda) \leq \min\{k, N\}$. Hence,

$$\hat{\rho}(\lambda) = \sum_{k=1}^\infty \frac{c_{k-N}(\lambda)}{2\sqrt{n}} m(k) \leq \frac{1}{2\sqrt{n}} \sum_{k=1}^N m(k) k + \frac{N}{2\sqrt{n}} \sum_{k=N+1}^\infty m(k).$$

Differentiating $m(x)$ three times, we obtain

$$m''(x) = \sum_{k=1}^\infty \frac{4}{x^{2k+3}} = \frac{4}{x^3(x^2-1)}.$$
whence there exists a constant $c > 0$ such that

$$
\hat{\rho}(\lambda) \leq \frac{c \ln N}{2\sqrt{n}} + \frac{c}{2\sqrt{n}}.
$$

\[ \square \]

**Lemma 5.2.** For any continuous bounded function $f : \mathbb{R} \to \mathbb{C}$, any integer vector $\vec{m}$, and any $\varepsilon > 0$, we have the following convergence in measure:

$$
\lim_{N \to \infty} \mathbb{P}_n^{(c^2 N^2)} \left\{ \lambda : \left| \frac{1}{cN} \sum_{k=0}^{\infty} f \left( \frac{k}{cN} \right) c_{k+\vec{m}}(\lambda) \right. \right.
$$

$$
\left. - \left( \int_{-\varepsilon}^{c+2} f(a) \mathbb{E}_{\phi(a)} c_{\vec{m}} \, da + \delta_{c<1} \int_{-\frac{1}{c}}^{c-2} f(a) \, da \right) \left| < \varepsilon \right. \right\} = 1.
$$

**Proof.** Let $\varepsilon_0 > 0$ and $1 > \delta > \frac{1}{3}$ be fixed. Throughout the proof, $C$ will denote an arbitrary constant that depends only on $\varepsilon_0$ and $f$. It follows from Propositions 4.12 and 3.7 that

$$
\left| f \left( \frac{k}{cN} \right) f \left( \frac{l}{cN} \right) \mathbb{E}_n^{(c^2 N^2)} \left( \left( c_{k+\vec{m}} - \mathbb{E}_{\phi(a)} c_{\vec{m}} \right) \cdot \left( c_{l+\vec{m}} - \mathbb{E}_{\phi(a)} c_{\vec{m}} \right) \right) \right|
$$

$$
\leq \frac{C}{\min\{N, (1+|k-l|)^2\}} \leq \frac{C}{1+|k-l|}
$$

for all $k, l \in \mathcal{I}_N(\varepsilon_0)$. Summing up over all such $k$ and $l$, we obtain

$$
\mathbb{E}_n^{(c^2 N^2)} \left| \frac{1}{cN} \sum_{k \in \mathcal{I}_N(\varepsilon_0)} f \left( \frac{k}{cN} \right) c_{k+\vec{m}} - \frac{1}{cN} \sum_{k \in \mathcal{I}_N(\varepsilon_0)} f \left( \frac{k}{cN} \right) \mathbb{E}_{\phi(a)} c_{\vec{m}} \right|^2
$$

$$
\leq \frac{C N \ln(N)}{N^2}.
$$

Replacing the Riemann sum by the appropriate integral we obtain

(38)

$$
\lim_{n \to \infty} \mathbb{P}_n^{(c^2 N^2)} \left| \frac{1}{cN} \sum_{k \in \mathcal{I}_N(\varepsilon_0)} f \left( \frac{k}{cN} \right) c_{k+\vec{m}} - \int_{-\varepsilon}^{c+2-\varepsilon_0} f(a) \mathbb{E}_{\phi(a)} c_{\vec{m}} \, da \right|^2 = 0.
$$

It follows from Proposition 3.9 that

$$
\lim_{N \to \infty} \mathbb{P}_n^{(c^2 N^2)} \left| \frac{1}{cN} \sum_{k \notin \mathcal{I}_N(1,\delta)} f \left( \frac{k}{cN} \right) c_{k+\vec{m}}(\lambda) - \delta_{c<1} \frac{1}{cN} \sum_{k \notin \mathcal{I}_N(1,\delta)} \sum_{k \geq -N} f \left( \frac{k}{cN} \right) \right| = 0.
$$
which, since $f$ is bounded, implies

$$
(39) \lim_{N \to \infty} \frac{1}{cN} \sum_{k \in \mathbb{Z}/N(0)} \sum_{k \geq -N} f \left( \frac{k}{cN} \right) c_{k+m}(\lambda) - \delta_{c<1} \int_{-\frac{1}{c}}^{c} f(a) \, da = 0.
$$

Combining (38) and (39), and taking the limit $\varepsilon_0 \to 0$ completes the proof.

**Corollary 5.3.** For any $\varepsilon > 0$ we have

$$
\lim_{N \to \infty} \mathbb{P}_N \left\{ \lambda : \left| \hat{\theta}(\lambda) - \sum_{k=1}^{\infty} \left( m(k) \int_{c-2}^{c+2} \mathbb{E}_{\mathcal{S}(\phi_a)c_{\{0\}}} - \mathbb{E}_{\mathcal{S}(\phi_a)c_{\{0,k\}}} \right) da \right| < \varepsilon \right\} = 1,
$$

where $\hat{\theta}(\lambda)$ and $m(k)$ are as in Proposition 2.2.

**Proof.** Given a Young diagram $\lambda$ and a positive integer $k$, let $h_k(\lambda)$ be the number of cells in $\lambda$ with hook length $k$. Since $h_k(\lambda)$ is equal to the number of pairs $(i, i-k)$ such that $c_i(\lambda) = 1$ and $c_{i-k}(\lambda) = 0$, we have

$$
h_k(\lambda) = \sum_{i=-\infty}^{\infty} (c_i(\lambda) - c_i(\lambda)c_{i-k}(\lambda)).
$$

Applying Lemma 5.2 for any $k \in \mathbb{N}$ and any $\varepsilon > 0$ we obtain

$$
(40) \lim_{N \to \infty} \mathbb{P}_N \left\{ \lambda : \left| \frac{h_k(\lambda)}{cN} - \int_{c-2}^{c+2} \mathbb{E}_{\mathcal{S}(\phi_a)c_{\{0\}}} - \mathbb{E}_{\mathcal{S}(\phi_a)c_{\{0,k\}}} \right| < \varepsilon \right\} = 1.
$$

Notice that

$$
\hat{\theta}(\lambda) = \sum_{k=1}^{\infty} \frac{h_k(\lambda)}{\sqrt{n}} m(k).
$$

Since each row of $\lambda$ can have at most one cell with hook length $k$ we have $h_k(\lambda) < N$, whence the expression

$$
\left| \frac{h_k(\lambda)}{cN} - \int_{c-2}^{c+2} \left( \mathbb{E}_{\mathcal{S}(\phi_a)c_{\{0\}}} - \mathbb{E}_{\mathcal{S}(\phi_a)c_{\{0,k\}}} \right) da \right|
$$

is bounded. Since the series $\sum_{k=1}^{\infty} m(k)$ is convergent, summing (40) in $k$ we obtain the statement of the corollary.

□
Define
\[ F_\lambda(x) = \sqrt{n} f_\lambda \left( \frac{x}{\sqrt{n}} \right) = \mathcal{L}_\lambda(x) - \sqrt{n} \Omega_c \left( \frac{x}{\sqrt{n}} \right). \]

We have
\[ \frac{\sqrt{n}}{8} \| f_\lambda \|_2^2 = \frac{1}{4 \sqrt{n}} \int_0^\infty \int_{-\infty}^\infty \left( \frac{F_\lambda(t + h) - F_\lambda(t)}{h} \right)^2 dt \, dh. \]

**Corollary 5.4.** For any \( h_0 > 0 \) and for any \( \varepsilon > 0 \) we have
\[
\lim_{N \to \infty} \lim_{n \to [\epsilon^4 N^2]} \mathbb{P}_n \left\{ \lambda : \left| \frac{1}{4 \sqrt{n}} \int_0^{h_0} \int_{-\infty}^\infty \left( \frac{F_\lambda(t + h) - F_\lambda(t)}{h} \right)^2 dt \, dh - \tilde{H}_c(h_0) \right| < \varepsilon \right\} = 1,
\]

where
\[
\tilde{H}_c(h_0) = \frac{1}{4} \int_{c-2}^{c+2} \int_0^1 \int_0^{h_0} \mathbb{E}_{\phi_a} \left( \frac{\mathcal{L}_\lambda(s + h) - \mathcal{L}_\lambda(s)}{h} - \frac{2}{\pi} \arcsin \left( \frac{c + a}{2 \sqrt{1 + ac}} \right) \right)^2 dh \, ds \, da.
\]

**Proof.** For any \( t \) and any \( h \) such that \( 0 < h \leq h_0 \), we have
\[
\left| \frac{cN}{h} \left( \Omega_c \left( \frac{t + h}{cN} \right) - \Omega_c \left( \frac{t}{cN} \right) \right) - \Omega'_c \left( \frac{t}{cN} \right) \right| \leq \frac{C(h_0)}{cN}.
\]

From (1) it follows that the integral in (41) is equal to the expression
\[
\frac{1}{4cN} \int_0^1 \int_0^{h_0} \sum_{k=-N}^{\infty} \left( \frac{\mathcal{L}_\lambda(s + k + h) - \mathcal{L}_\lambda(s + k)}{h} - \frac{\Omega'_c(s + k)}{cN} \right)^2 dh \, ds
\]
up to \( o(1) \). From the definition of \( c_k(\lambda) \) (see Section 3.2) it follows that we can write
\[
\frac{\mathcal{L}_\lambda(s + k + h) - \mathcal{L}_\lambda(s + k)}{h} = 1 - 2 \frac{(1 - s)}{h} c_k(\lambda) - \sum_{i=1}^{h-1} \frac{2}{h} c_{k+i}(\lambda) - 2 \frac{s}{h} c_{k+h}(\lambda),
\]
which implies that the expression in (42) can be written in the form
\[
\frac{1}{cN} \sum_{\tilde{m} \in I_{h_0}} \sum_k f \left( \frac{k}{cN} \right) c_{k+\tilde{m}}
\]
for some finite set \( I_{h_0} \). Thus, we can apply Lemma 5.2 to (42), and obtain the corollary (it is easy to check that the contributions coming from the term \( \delta_{c<1} \int f(a) \, da \) in Lemma 5.2 cancel out).
Lemma 5.5 (The tail estimate). For any $\varepsilon > 0$ there exists $h_0 > 0$ such that

$$
\lim_{N \to \infty} \mathbb{P}_N \left\{ \lambda : \frac{1}{4\sqrt{n}} \int_{h_0}^{\infty} \int_{-\infty}^{\infty} \left( \frac{F_{\lambda}(t+h) - F_{\lambda}(t)}{h} \right)^2 \, dt \, dh < \varepsilon \right\} = 1.
$$

The proof of Lemma 5.5 is given in Section 6. We now prove Theorem 1.1.

Proof. [of Theorem 1.1] It follows from Corollary 3.10 that

$$
\lim_{n \to \infty} \mathbb{P}_N \left\{ \lambda : \left| \frac{\sqrt{n}}{2} \int_{|x-c| > 2} G_c(x) f_{\lambda}(x) \, dx \right| < \varepsilon \right\} = 1
$$

for any $\varepsilon > 0$. The theorem follows immediately from Proposition 2.2,Corollaries 5.3 and 5.4 and Lemmas 5.1 and 5.5. For the constant $H_c$ we obtain the following formula:

$$
H_c = \sum_{k=1}^{\infty} \left( m(k) \int_{c-2}^{c+2} \mathbb{E}_{\xi}\mathbb{E}_{\phi_a} c_{\{0\}} - \mathbb{E}_{\xi}\mathbb{E}_{\phi_a} c_{\{0,k\}} \, da \right)
+ \frac{1}{4} \int_{c-2}^{c+2} \int_{0}^{1} \int_{0}^{\infty} \mathbb{E}_{\xi}\mathbb{E}_{\phi_a} \left( \frac{F_{\lambda}(s+h) - F_{\lambda}(s)}{h} - \frac{2}{\pi} \arcsin \left( \frac{c + a}{2\sqrt{1 + ac}} \right) \right)^2 \, dh \, ds \, da.
$$

The tail estimate

The goal of this section is to prove Lemma 5.5. To simplify notation, in this section we set $n = c^2 N^2$.

For $\delta > 0$ and $K > 0$ denote

$$
F_{\lambda}^{K,\delta}(k) = \begin{cases} F_{\lambda}(k), & k \in I_N^+(K, \delta) \\ 0, & \text{otherwise} \end{cases}
$$

and

$$
F_{\lambda}(k, l) = \left( \frac{F_{\lambda}(k + l) - F_{\lambda}(k)}{l} \right)^2.
$$

Notice that $F_{\lambda}(x)$ is a Lipschitz function with Lipschitz constant 2. It was proven in [Buf10] that for a Lipschitz function with Lipschitz constant 2 the truncated integral in the $\frac{1}{2}$-Sobolev norm can be approximated by a sum of the integrand. More precisely, Lemma 6.1 in [Buf10] implies:
Lemma 6.1. For any $\delta \in (0, \frac{1}{2})$, any $K > 0$, $L > 0$ and any $\varepsilon > 0$, there exists a number $h_0 > 1$ depending only on $\delta, K, L, \varepsilon$ and such that for all $h > h_0$, all $N \in \mathbb{N}$, $n = c^2 N^2$, and all $\lambda \in \mathbb{Y}_n^*(K, \delta)$ we have the inequality

$$\frac{1}{4\sqrt{n}} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \left( \frac{F_\lambda(t + h) - F_\lambda(t)}{h} \right)^2 \, dt \, dh \leq \frac{1}{\sqrt{n}} \sum_{l=h}^{\infty} \sum_{k=-\infty}^{\infty} \left( \frac{F(L, \delta)^\lambda_k(k + l) - F(L, \delta)^\lambda_k(k)}{l} \right)^2 + \varepsilon.$$ 

We now prove Lemma 5.5.

Proof. [of Lemma 5.5] Fix $L > 0$ and $\delta \in (\frac{1}{3}, \frac{1}{2})$. It follows from Corollary 3.10 that we can restrict to the Young diagrams in the set $\mathbb{Y}_n^*(L, \delta)$. Separating the terms where $F(L, \delta)^\lambda_k(k + l) = 0$ or $F(L, \delta)^\lambda_k(k) = 0$, we obtain

$$\frac{1}{cN} \sum_{l=h}^{\infty} \sum_{k=-\infty}^{\infty} \left( \frac{F(L, \delta)^\lambda_k(k + l) - F(L, \delta)^\lambda_k(k)}{l} \right)^2 \leq \frac{1}{cN} \sum_{k,k+l \in \mathcal{I}_N(L, \delta)} F_\lambda(k, l) + \frac{2}{cN} \sum_{k \in \mathcal{I}_N(L, \delta)} \frac{F_\lambda(k)^2}{\text{dist}(k, \mathbb{Z} \setminus \mathcal{I}_N(L, \delta))}.$$ 

It is easy to see that if $k \in \mathcal{I}_N(L, \delta)$, then

$$F(L, \delta)^\lambda_k(k + 1) - F(L, \delta)^\lambda_k(k) = 1 - 2c_k(\lambda) - cN \left( \Omega_c \left( \frac{k + 1}{cN} \right) - \Omega_c \left( \frac{k}{cN} \right) \right).$$

Using Theorem 3.2 and (13) we obtain

$$F(L, \delta)^\lambda_k(k + 1) - F(L, \delta)^\lambda_k(k) = 2 \left( E_{p_N^\gamma + c} - c_k(\lambda) \right) + 2 \left( \frac{\phi_k}{\pi} - K_{N, \gamma}(k, k) \right) + \left( \frac{2}{\pi} \arcsin \left( \frac{c + \frac{k}{cN}}{2\sqrt{1 + \frac{k}{cN}}} \right) - cN \left( \Omega_c \left( \frac{k + 1}{cN} \right) - \Omega_c \left( \frac{k}{cN} \right) \right) \right).$$

Since $\Omega_c'(x)$ is given by (1) and

$$\Omega_c''(x) = \frac{2 - c^2 + cx}{2(1 + cx)\sqrt{4 - (x - c)^2}},$$
from the second degree Taylor polynomial approximation of $\Omega_c$ it follows that there exists a constant $C > 0$ such that

\[
\left| \frac{2}{\pi} \arcsin \left( \frac{c + \frac{k}{cN}}{2\sqrt{1 + \frac{k}{N}}} \right) - cN \left( \Omega_c \left( \frac{k+1}{cN} \right) - \Omega_c \left( \frac{k}{cN} \right) \right) \right| \leq \frac{C}{\sqrt{4c^2N^2 - (k - c^2N)^2}}
\]

for all $k \in \mathcal{I}_N^{-}(L, \delta)$.

It follows from Lemma 3.6 that there exist constants $C_1, C_2 > 0$ such that for all $k \in \mathcal{I}_N^{-}(L, \delta)$ and for all $\gamma^+$ we have

\[
\left| \frac{\Phi_k}{\pi} - K_{N, \gamma^+}(k, k) \right| \leq \frac{C_1 e^{C_2 |\gamma^+-cN|}}{2cN - |k - c^2N|}.
\]

Since $\mathbb{E}_{F_N^{\gamma^+,0}}(c_k) = K_{N, \gamma^+}(k, k)$, combining (45), (46) and (47) we obtain

\[
F_\lambda(k, l) \leq 2 \frac{1}{l^2} \text{Var}_{F_N^{\gamma^+,0}}(c_k + \cdots + c_{k+l-1}) + \frac{1}{l^2} \sum_{j=k}^{k+l-1} \frac{C_1 e^{C_2 |\gamma^+-cN|}}{2cN - \lfloor j - c^2N \rfloor},
\]

for some constants $C_1, C_2 > 0$ and for all $k$ and $l$ such that $k, k+l \in \mathcal{I}_N^{-}(L, \delta)$.

Summing the second term on the left–hand side of (48) we obtain

\[
\text{Var}_{F_N^{\gamma^+,0}}(c_k + \cdots + c_{k+l-1}) \leq \frac{1}{cN} \sum_{l=h}^{4cN} \frac{1}{l^2} \left( \frac{\ln(l + 1)}{l^2} - \frac{\ln(l)}{l^2} \right)^2 \leq \frac{8}{cN} \sum_{l=h}^{4cN} \frac{\ln(l)}{l^2} \leq 8 \frac{\ln(N)}{h}.
\]

Combining this with the estimate of the variance given in Lemma 6.2 below, we obtain

\[
\frac{1}{cN} \sum_{l=h}^{4cN} \sum_{k, k+l \in \mathcal{I}_N^{-}(L, \delta)} F_\lambda(k, l) \leq C_1 e^{C_2 |\gamma^+-cN|} \frac{\ln(N)}{h}.
\]

We now turn to estimating the second sum on the right–hand side of (44). We will estimate the sum when $k$ is in the left half of the interval $\mathcal{I}_N^{-}(L, \delta)$, i.e. when $k$ is larger than $c^2N$. The sum when $k < c^2N$ can be estimated completely similarly. Denote

\[
M_N(L, \delta) = \max\{M : M \in \mathcal{I}_N^{-}(L, \delta)\}.
\]
We have
\[ M_N(L, \delta) = 2cN - LcN^\delta + c^2N \]
and
\[ \text{dist}(k, \mathbb{Z}\setminus \mathcal{I}_N(L, \delta)) = M_N(L, \delta) - k. \]

Notice that
\[ (50) \quad F_\lambda(k)^2 \leq 2(F_\lambda(k) - F_\lambda(M_N(L, \delta)))^2 + 2F_\lambda(M_N(L, \delta))^2. \]

Since \( F_\lambda \) is Lipschitz with constant 2 and \( \lambda \in \mathcal{Y}_N^\delta(L, \delta) \), we have
\[ |F_\lambda(M_N(L, \delta))| \leq 4LN^\delta, \]
which implies
\[ (51) \quad \frac{2}{cN} \sum_{k \in \mathcal{I}_N(L, \delta)} F_\lambda(M_N(L, \delta))^2 \leq \frac{32L^2N^{2\delta} \ln(4cN)}{cN}. \]

Since
\[ \frac{2}{cN} \sum_{k \in \mathcal{I}_N(L, \delta), k > c^2N} \left( \sum_{j=k}^{M_N(L, \delta)} \frac{1}{2cN-j-c^2N} \right)^2 \leq \frac{2}{cN} \sum_{k \in \mathcal{I}_N(L, \delta), k > c^2N} \frac{(\ln(M_N(L, \delta) - k))^2}{M_N(L, \delta) - k} \leq \frac{2(\ln(4cN))^3}{cN}, \]
ite follows from (48), (50) and (51) that
\[ \frac{2}{cN} \sum_{k \in \mathcal{I}_N(L, \delta), k > c^2N} \frac{F_\lambda(k)^2}{M_N(L, \delta) - k} \leq \frac{4}{cN} \sum_{k \in \mathcal{I}_N(L, \delta), k > c^2N} \text{Var}_{\mathcal{F}_N^\delta} \left( c_k + \cdots + c_{M_N(L, \delta)} \right) \frac{M_N(L, \delta) - k}{M_N(L, \delta) - k} + \frac{C_1e^{C_2|\gamma-c^2N|} \ln(4cN)}{N^{1-2\delta}}. \]

Using the estimate of the variance given in Lemma 6.3 below, we obtain
\[ \frac{2}{cN} \sum_{k \in \mathcal{I}_N(L, \delta), k > c^2N} \frac{F_\lambda(k)^2}{M_N(L, \delta) - k} \leq \frac{C_1e^{C_2|\gamma-c^2N|}}{N^{1+\tau}}. \]
Combining this with (49) we obtain
\[
\mathbb{E}_{\mathbb{P}_N^{\gamma^+,0}} \left( \frac{1}{\sqrt{n}} \sum_{l=h}^{\infty} \sum_{k=-\infty}^{\infty} \left( \frac{F_{\lambda,L}(k+l) - F_{\lambda,L}(k)}{l} \right)^2 \right)
\leq C_1 e^{C_2 |\gamma^+ - c^2 N|} \left( \frac{1}{N^\delta} + \frac{(\ln h)^2}{h} \right),
\]
which implies the Lemma after depoisonization. \qed

**Lemma 6.2.** Let
\[
V_{\lambda,N}^{L,\delta}(h) = \frac{1}{N} \sum_{k,k+l \in \mathcal{I}^{-}_N(L,\delta)} \frac{1}{l^2} \text{Var}_{\mathbb{P}_N^{\gamma^+,0}} (c_k + \ldots + c_{k+l-1}).
\]
For any \( \delta > \frac{1}{3} \) and \( L > 0 \) there exist constants \( C_1 > 0 \) and \( C_2 > 0 \) such that for any \( h > 0 \) there exists \( N_0 \) such that for all \( N > N_0 \) and all \( \gamma^+ \) we have
\[
V_{\lambda,N}^{L,\delta}(h) \leq C_1 e^{C_2 |\gamma^+ - c^2 N|} \frac{\ln h}{h}.
\]

**Proof.** We can assume \( h < N^\delta \). Throughout the proof, \( C_1 \) and \( C_2 \) will denote arbitrary constants that depend only on \( L \) and \( \delta \). It is immediate from (8) that
\[
\text{Var}_{\mathbb{P}_N^{\gamma^+,0}} (c_k + \ldots + c_{k+l-1}) = \sum_{x \in \mathcal{I}^{-}_N(L,\delta)} \sum_{y \in \mathbb{Z}} K_{N,\gamma^+}(x,y)K_{N,\gamma^+}(y,x).
\]
Summing over \( k, k+l \in \mathcal{I}^{-}_N(L,\delta), l \geq h \), we obtain
\[
V_{\lambda,N}^{L,\delta}(h) = \frac{1}{N} \sum_{k,k+l \in \mathcal{I}^{-}_N(L,\delta)} \sum_{l \geq h} \sum_{x \in [k,k+l-1]} \sum_{y \notin [k,k+l-1]} \frac{K_{N,\gamma^+}(x,y)K_{N,\gamma^+}(y,x)}{l^2}.
\]

Let \( P^h_N(x,y) \) be the coefficient of \( K_{N,\gamma^+}(x,y)K_{N,\gamma^+}(y,x) \) in the above sum and let
\[
Q^h_{N,\gamma^+}(x,y) = P^h_N(x,y)K_{N,\gamma^+}(x,y)K_{N,\gamma^+}(y,x).
\]
We have
\[
V_{\lambda,N}^{L,\delta}(h) = \frac{1}{N} \sum_{x \in \mathcal{I}^{-}_N(L,\delta)} Q^h_{N,\gamma^+}(x,y).
When \( x \in \mathcal{I}_N^{-}(L, \delta) \) and \( y \in \mathcal{I}_N^{+}(L, \delta) \), estimating from above the number of intervals of length \( l \geq h \) that contain \( x \) but not \( y \), we obtain
\[
P_N^h(x, y) \leq 2 \sum_{l=h}^{\infty} \min\{|x-y|, l\} \leq \psi(h, |x-y|),
\]
where
\[
\psi(h, l) = \begin{cases} 
\frac{2l}{h-1}, & l \leq h \\
4\ln l, & l > h.
\end{cases}
\]

Since for a fixed \( l \) the number of pairs \( x, y \in \mathcal{I}_N^{-}(L, \delta) \) such that \( |x-y| = l \) is less than \( 4cN \), it follows from Remark 4.8 that
\[
\frac{1}{N} \sum_{x \in \mathcal{I}_N^{-}(L, \delta)} \sum_{y \in \mathcal{I}_N^{+}(\frac{L}{2}, \delta) \setminus \mathcal{I}_N(\varepsilon)} |Q_N^{h}(x, y)| \leq C_1 e^{C_2|\gamma^+-c^2|N} \frac{\ln h}{h}.
\]

Similarly, it follows from Lemma 4.7 with \( \delta_1 = \delta_2 = 1 \) that for any \( \varepsilon > 0 \),
\[
\frac{1}{N} \sum_{x, y \in \mathcal{I}_N(\varepsilon)} |Q_N^{h}(x, y)| \leq C_1 e^{C_2|\gamma^+-c^2|N} \frac{\ln h}{h}.
\]

If \( x \in \mathcal{I}_N^{-}(L, \delta) \), \( y \in \mathcal{I}_N^{-}(\frac{L}{2}, \delta) \setminus \mathcal{I}_N(\varepsilon) \), and \( x \) and \( y \) have opposite signs, then
\[
\frac{2cN}{3} \leq |x-y| \leq 4cN,
\]
whence Lemma 4.7 implies
\[
|Q_N^{h}(x, y)| \leq C_1 e^{C_2|\gamma^+-c^2|N} \frac{N^{1-\delta} \ln N}{N^2}.
\]

Since the cardinality of the set \( \mathcal{I}_N^{-}(L, \delta) \times (\mathcal{I}_N^{-}(\frac{L}{2}, \delta) \setminus \mathcal{I}_N(\varepsilon)) \) is less than \( 16c^2N^2 \), we obtain
\[
\frac{1}{N} \sum_{x \in \mathcal{I}_N^{-}(L, \delta)} \sum_{y \in \mathcal{I}_N^{+}(\frac{L}{2}, \delta) \setminus \mathcal{I}_N(\varepsilon)} |Q_N^{h}(x, y)| \leq C_1 e^{C_2|\gamma^+-c^2|N} \frac{\ln N}{N^3}.
\]

If \( x \in \mathcal{I}_N^{-}(L, \delta) \) and \( y \in \mathcal{I}_N^{+}(\frac{L}{2}, \delta) \setminus \mathcal{I}_N^{-}(\frac{L}{2}, \delta) \), then \( \frac{1}{2}cLN^\delta < |x-y| < 5cN \), whence Lemma 4.9 implies
\[
|Q_N^{h}(x, y)| \leq C_1 e^{C_2|\gamma^+-c^2|N} \frac{N^{5-3\delta} \ln N}{(1 + |x-y|)^2}.
\]

Since the cardinality of \( \mathcal{I}_N^{+}(\frac{L}{2}, \delta) \setminus \mathcal{I}_N^{-}(\frac{L}{2}, \delta) \) is less than \( LcN^\delta \) and for a fixed
\[
y \in \mathcal{I}_N^{+}(\frac{L}{2}, \delta) \setminus \mathcal{I}_N^{-}(\frac{L}{2}, \delta)
\]
we have
\[ \sum_{x \in \mathcal{I}_N^{-}(L, \delta)} \frac{1}{(1 + |x-y|)^2} \leq \frac{2}{LcN^\delta}, \]
we obtain
\[ (56) \quad \frac{1}{N} \sum_{\substack{x \in \mathcal{I}_N^{-}(L, \delta) \backslash \mathcal{I}_N^{+}(L, \frac{L}{2}, \delta) \setminus \mathcal{I}_N(L, \delta) \setminus \mathcal{I}_N^{-}(\frac{L}{2}, \delta) \setminus \mathcal{I}_N^+ \setminus \mathcal{I}_N}} |Q^{h}_{N, \gamma^+}(x,y)| \leq C_1 e^{C_2 |\gamma^+ - \gamma|^2} e^{-C_3 N^{\frac{3}{2}} - \frac{1}{2}} \frac{\ln N}{N^{\frac{1}{2} + \frac{1}{2}}}. \]

When \( x \in \mathcal{I}_N^{-}(L, \delta) \) and \( y \notin \mathcal{I}_N^+(L, \delta) \), summing over all subintervals of \( \mathcal{I}_N^{-}(L, \delta) \) of length at least \( h \), we obtain
\[ P^h_N(x,y) \leq \sum_{l=0}^{\mathcal{I}_N^{-}(L, \delta)} \frac{|\mathcal{I}_N^{-}(L, \delta) - l|}{l^2} \leq \frac{N}{h-1}. \]
Using Lemma 4.10 to estimate \( |K_{N, \gamma^+}(x,y)K_{N, \gamma^+}(y,x)| \), we obtain
\[ (57) \quad \frac{1}{N} \sum_{\substack{x \in \mathcal{I}_N^{-}(L, \delta) \backslash \mathcal{I}_N^{+}(L, \delta) \setminus \mathcal{I}_N}} |Q^{h}_{N, \gamma^+}(x,y)| \leq C_1 e^{C_2 |\gamma^+ - \gamma|^2} e^{-C_3 N^{\frac{3}{2}} - \frac{1}{2}} \frac{\ln N}{N^{\frac{1}{2} + \frac{1}{2}}}. \]
Combining the estimates (53), (54), (55), (56) and (57) completes the proof.

**Lemma 6.3.** For any \( \delta > \frac{1}{3} \) and \( L > 0 \) there exist constants \( C_1 > 0 \) and \( C_2 > 0 \) such that for any \( h > 0 \) there exists \( N_0 \) such that for all \( N > N_0 \) and all \( \gamma^+ \) we have
\[ \frac{2}{cN} \sum_{\substack{k \in \mathcal{I}_N^{-}(L, \delta) \backslash \mathcal{I}_N^{+}(L, \delta) \setminus \mathcal{I}_N}} \frac{\text{Var}_{\mathbb{P}_{N}^{\gamma^+,0}}(ck + \cdots + c_{M_N(L, \delta)})}{M_N(L, \delta) - k} \leq C_1 e^{C_2 |\gamma^+ - \gamma|^2} \frac{\ln N}{N^{\frac{1}{2} + \frac{1}{2}}}. \]

**Proof.** Using (52) we can write the sum of the variance in the form
\[ \frac{2}{cN} \sum_{\substack{k \in \mathcal{I}_N^{-}(L, \delta) \backslash \mathcal{I}_N^{+}(L, \delta) \setminus \mathcal{I}_N}} \frac{\text{Var}_{\mathbb{P}_{N}^{\gamma^+,0}}(ck + \cdots + c_{M_N(L, \delta)})}{M_N(L, \delta) - k} = \frac{2}{cN} \sum_{\substack{x \in \mathcal{I}_N^{-}(L, \delta) \backslash \mathcal{I}_N^{+}(L, \delta) \setminus \mathcal{I}_N}} S^h_{N, \gamma^+}(x,y), \]
where
\[ S^h_{N, \gamma^+}(x,y) = R^h_N(x,y)K_{N, \gamma^+}(x,y)K_{N, \gamma^+}(y,x). \]
and

\[ R_N^h(x, y) = \begin{cases} 
  \sum_{k=y}^{x-1} \frac{1}{M_N(L, \delta) - k}, & y \in (c^2N, x) \\
  \sum_{k=c^2N}^{x-1} \frac{1}{M_N(L, \delta) - k}, & y < c^2N \text{ or } y > M_N(L, \delta)
\end{cases} \]

Since

\[ R_N^h(x, y) \leq \frac{|x - y|}{M_N(L, \delta) - x} \text{ if } y \in \mathcal{I}_N^+(L, \delta), \]

it follows from Lemma 4.9 that

\[ \frac{2}{cN} \sum_{x \in \mathcal{I}_N^-(L, \delta)} S_{N, \gamma +}^h(x, y) \leq C_1 e^{C_2|\gamma^+ - c^2N|} \left( \frac{\ln M_N(L, \delta)}{N^{\frac{1}{2}}} \right)^2 \leq \frac{C_1 e^{C_2|\gamma^+ - c^2N|}}{N^{\frac{1}{2}}} \]

Since

\[ R_N^h(x, y) \leq \frac{4cN}{M_N(L, \delta) - x} \text{ if } y \notin \mathcal{I}_N^+(L, \delta), \]

it follows from Lemma 4.10 that

\[ \frac{2}{cN} \sum_{x \in \mathcal{I}_N^-(L, \delta)} S_{N, \gamma +}^h(x, y) \leq C_1 e^{C_2|\gamma^+ - c^2N|} e^{-C_3N^{\frac{1}{N}} - \frac{1}{2}} \]

Combining the estimates (58) and (59) completes the proof.

\[ \square \]
