A KACZMARZ ALGORITHM FOR SOLVING TREE BASED DISTRIBUTED SYSTEMS OF EQUATIONS

CHINMAY HEGDE, FRITZ KEINERT, AND ERIC S. WEBER

Abstract. The Kaczmarz algorithm is an iterative method for solving systems of linear equations. We introduce a modified Kaczmarz algorithm for solving systems of linear equations in a distributed environment, i.e., the equations within the system are distributed over multiple nodes within a network. The modification we introduce is designed for a network with a tree structure that allows for passage of solution estimates between the nodes in the network. We prove that the modified algorithm converges under no additional assumptions on the equations. We demonstrate that the algorithm converges to the solution, or the solution of minimal norm, when the system is consistent. We also demonstrate that in the case of an inconsistent system of equations, the modified relaxed Kaczmarz algorithm converges to a weighted least squares solution as the relaxation parameter approaches 0.

1. Introduction

The Kaczmarz method ([11], 1937) is an iterative algorithm for solving a system of linear equations $A\vec{x} = \vec{b}$, where $A$ is an $m \times k$ matrix. Written out, the equations are $\vec{a}_i \cdot \vec{x} = b_i$ for $i = 1, \ldots, m$, where $\vec{a}_i^T$ is the $i$th row of the matrix $A$, and we take the dot product to be linear in both variables. Given a solution guess $\vec{x}^{(n)}$ and an equation number $i$, we calculate $r_i = b_i - \vec{a}_i \cdot \vec{x}^{(n)}$ (the residual for equation $i$), and define

$$\vec{x}^{(n+1)} = \vec{x}^{(n)} + \frac{r_i}{\|\vec{a}_i\|^2} \vec{a}_i.$$ 

This makes the residual of $\vec{x}^{(n+1)}$ in equation $i$ equal to 0. Here and elsewhere, $\| \cdot \|$ is the usual Euclidean ($\ell^2$) norm. We iterate repeatedly through all equations (i.e., we consider $\lim_{n \to \infty} \vec{x}^{(n)}$ where $n + 1 \equiv i \mod m$). Kaczmarz proved that if the system of equations has a unique solution, then $\vec{x}^{(n)}$ converges to that solution. Later, it was proved in [23] that if the system is consistent (but the solution is not unique), then the sequence converges to the solution of minimal norm. Likewise, it was proved in [4, 14] that if inconsistent, a relaxed version of the algorithm can provide approximations to a weighted least-squares solution.

Obtaining the $n + 1$ estimate requires knowledge only of the $i$-th equation ($n + 1 \equiv i \mod m$ as above) and the $n$-th estimate. We suppose that the equations are indexed by the nodes of a tree, representing a network in which the equations are distributed over many nodes. In our distributed Kaczmarz algorithm, solution estimates can only be communicated when there exists an edge between the nodes. The estimates for the solution will disperse through the tree, which results in several different estimates of the solution. When these estimates then reach the leaves of the tree, they are pooled together into a single estimate. Using this single estimate as a seed, the process is repeated, with the goal that the sequence...
of single estimates will converge to the true solution. We illustrate the dispersion and pooling processes in Figure 1.

\[ \vec{a}_v \cdot \vec{x} = b_v \]
\[ \vec{a}_{\ell_t} \cdot \vec{x} = b_{\ell_t} \]
\[ \vec{a}_r \cdot \vec{x} = b_r \]

(a) equations indexed by vertices
(b) pooling (illustrated by mirroring) with successive iterations

**Figure 1.** Illustration of equations indexed by nodes of the tree.

1.1. **Notation.** For linear transformations \( T \), we denote by \( \mathcal{N}(T) \) and \( \mathcal{R}(T) \) the kernel (nullspace) and range, respectively.

As mentioned previously, our notation is that the dot product of two vectors \( \vec{x} \cdot \vec{z} = \sum_k x_k z_k \) is linear in both variables. We use \( \langle \cdot, \cdot \rangle \) to denote the inner product on \( \mathbb{C}^d \) which is sesquilinear. In the sequel, we will use the linear transformation notation (rather than dot product notation):

\[
S_{\vec{a}} : \mathbb{C}^d \to \mathbb{C} : \vec{z} \mapsto \vec{a} \cdot \vec{z}.
\]

When the vector \( \vec{a} = \vec{a}_i \) corresponds to a row of the matrix \( A \) indexed by a natural number \( i \), or when \( \vec{a} = \vec{a}_v \) corresponds to a row of the matrix \( A \) indexed by a node \( v \), we will denote the transformation in Equation (2) by \( S_i \) or \( S_v \), respectively. We use \( P_v \) to denote the linear projection onto \( \mathcal{N}(S_v) \):

\[
P_v(\vec{z}) = (I - S_v^* (S_v S_v^*)^{-1} S_v) (\vec{z})
\]

and \( Q_v \) to denote the affine projection onto the linear manifold \( S_v(\vec{z}) = b_v \):

\[
Q_v(\vec{z}) = P_v(\vec{z}) + \vec{h}_v
\]

where \( \vec{h}_v \) is the vector that satisfies \( S_v(\vec{h}_v) = b_v \) and is orthogonal to \( \mathcal{N}(S_v) \).

A tree is a connected graph with no cycles. We denote arbitrary nodes (vertices) of a tree by \( v \), \( u \). Our tree will be rooted; the root of the tree is denoted by \( r \). Following the notation from MATLAB, when \( v \) is on the path from \( r \) to \( u \), we will say that \( v \) is a predecessor of \( u \) and write \( u \prec v \). Conversely, \( u \) is a successor of \( v \). By immediate successor of \( v \) we mean a successor \( u \) such that there is an edge between \( v \) and \( u \) (this is referred to as a child in graph theory parlance \([25]\)). Similarly, \( v \) is an immediate predecessor (i.e. parent). We denote the set of all immediate successors of node \( v \) by \( \mathcal{C}(v) \). A node without a successor is called a leaf; leaves of the tree are denoted by \( \ell \). We will denote the set of all leaves by \( \mathcal{L} \). Often we will have need to enumerate the leaves as \( \ell_1, \ldots, \ell_t \), hence \( t \) denotes the number of leaves.

A weight \( w \) is a nonnegative function on the edges of the tree; we denote this by \( w(u,v) \), where \( u \) and \( v \) are nodes that have an edge between them. We assume \( w(u,v) = w(v,u) \).
though we will typically write $w(u, v)$ when $u \prec v$. When $u \prec v$, but $u$ is not a immediate successor, we write

$$w(u, v) := \prod_{j=1}^{J-1} w(u_{j+1}, u_j)$$

where $u = u_1, \ldots, u_J = v$ is a path from $u$ to $v$.

When the system of equations $A\vec{x} = \vec{b}$ has a unique solution, we will denote this by $\vec{x}^S$. When the system is consistent but the solution is not unique, we denote the solution of minimal norm by $\vec{x}^M$, which is given by

$$\vec{x}^M = \arg\min \{\|\vec{x}\| : A\vec{x} = \vec{b}\}.$$

1.2. The Distributed Kaczmarz Algorithm. The iteration begins with an estimate, say $\vec{x}^{(n)}$ at the root of the tree (we denote this by $\vec{x}^{(n)}_r$). Each node $u$ receives from its immediate predecessor $v$ an input estimate $\vec{x}^{(n)}_v$ and generates a new estimate via the Kaczmarz update:

$$\vec{x}^{(n)}_u = \vec{x}^{(n)}_v + \frac{r_u(\vec{x}^{(n)}_v)}{\|\vec{a}_u\|^2} \vec{a}_u,$$

where the residual is given by

$$r_u(\vec{x}^{(n)}_v) := b_u - S_u \vec{x}^{(n)}_v.$$

Node $u$ then passes this estimate to all of its immediate successors, and the process is repeated recursively. We refer to this as the dispersion stage. Once this process has finished, each leaf $\ell$ of the tree now possesses an estimate: $\vec{x}^{(n)}_\ell$.

The next stage, which we refer to as the pooling stage, proceeds as follows. For each leaf, set $\vec{y}^{(n)}_\ell = \vec{x}^{(n)}_\ell$. Each node $v$ receives as input the several estimates $y^{(n)}_u$ from all immediate successors $u$, and calculates an updated estimate as:

$$\vec{y}^{(n)}_v = \sum_{u \in C(v)} w(u, v) y^{(n)}_u,$$

subject to the constraints that $w(u, v) > 0$ when $u \in C(v)$ and $\sum_{u \in C(v)} w(u, v) = 1$. This process continues until reaching the root of the tree, resulting in the estimate $\vec{y}^{(n)}_r$.

We set $\vec{x}^{(n+1)} = \vec{y}^{(n)}_r$, and repeat the iteration. The updates in the dispersion stage (Equation 7) and pooling stage (Equation 9) are illustrated in Figure 2

1.3. Related Work. The Kaczmarz method was originally introduced in ([11], 1937). It became popular with the introduction of Computer Tomography, under the name of ART (Algebraic Reconstruction Technique). ART added non-negativity and other constraints to the standard algorithm [5]. Other variations on the Kaczmarz method allowed for relaxation parameters [23], re-ordering equations to speed up convergence [6], or considering block versions of the Kaczmarz method with relaxation matrices $\Omega_i$ [4]. Relatively recently, choosing the next equation randomly has been shown to dramatically improve the rate of convergence of the algorithm [22, 17, 18]. Moreover, this randomized version of the Kaczmarz algorithm has been shown to comparable to the gradient descent method [16]. Our version of the Kaczmarz method differs from these in that the next equation cannot be chosen randomly or otherwise, since the ordering of the equations is determined a priori by the network topology.
Our version is motivated by the situation in which the equations (or measurements) are distributed over a network. Distributed estimation problems have a long history in applied mathematics, control theory, and machine learning. At a high level, similar to our approach, they all involve averaging local copies of the unknown parameter vector interleaved with update steps \cite{24, 26, 21, 2, 15, 10, 28, 19, 29, 20}. One common form of the parameter estimation problem involves posing it as a consensus problem, where the goal is for nodes in a given graph to arrive at a common solution, assuming that no exchange of measurements takes place and only estimates are shared across neighbors. Computations are often not synchronized, and network connections may be unstable. Computations done with gossip methods are usually quite simple, such as computing averages, and converge only slowly.

Following \cite{28}, a consensus problem takes the following form. Consider the problem of minimizing:

\[ F(\bar{x}) = \sum_{v=1}^{m} f_v(\bar{x}), \]

where \( f_v \) is a function that is known (and private) to node \( v \) in the graph. Then, one can solve this minimization problem using decentralized gradient descent, where each node updates its estimate of \( \bar{x} \) (say \( \bar{x}_v \)) by combining the average of its neighbors with the negative gradient of its local function \( f_v \):

\[ \bar{x}_v^{(n+1)} = \frac{1}{\deg v} \sum_u m(v, u)\bar{x}_u^{(n)} - \omega \nabla f_v(\bar{x}_u^{(n)}), \]

where \( M = (m(v, u)) \in \{0, 1\}^{m \times m} \) represents the adjacency matrix of the graph. Specializing \( f_v(\bar{x}) = c_v(b_v - \bar{a}_v \cdot \bar{x})^2 \) yields our least-squares estimation problem that we establish in Theorem 14 (where \( c_v \) is a fixed weight for each node).

However, our version of the Kaczmarz method differs from previous work in a few aspects: (i) we assume a specific (tree) topology; (ii) our updates are asynchronous (the update time for each node is a function of its distance from the root); and (iii) as we will emphasize in Theorem 14, we make no strong convexity assumptions.

On the other end of the spectrum are algorithms that distribute a computational task over many processors arranged in a fixed network. These algorithms are usually considered in the context of parallel processing, where the nodes of the graph represent CPUs in a highly
parallelized computer. This setup can handle large computational tasks, but the problem must be amenable to being broken into independent pieces. See [1] for an overview.

The algorithm we are considering does not really fit either of those categories. It requires more structure than the gossip algorithms, but each node depends on results from other nodes, more than the usual distributed algorithms.

This was pointed out in [1]. For iteratively solving a system of linear equations, an SOR variant of the Jacobi method is easy to parallelize; standard SOR, which is a variation on Gauss-Seidel, is not. The authors also consider what they call the Reynolds method, which is similar to a Kaczmarz method with all equations being updated simultaneously. Again, this method is easy to parallelize. A sequential version called RGS (Reynolds Gauss-Seidel) can only be parallelized in certain settings, such as the numerical solution of PDEs.

A distributed version of the Kaczmarz algorithm was introduced in [12]. The main ideas presented there are very similar to ours: updated estimates are obtained from prior estimates using the Kaczmarz update with the equations that are available at the node, and distributed estimates are averaged together at a single node (which the authors refer to as a fusion center, for us it is the root of the tree). In [12], the convergence analysis is limited to the case of consistent systems of equations, and inconsistent systems are handled by Tikhonov regularization [9, 7] rather than by varying the relaxation parameter.

Finally, the Kaczmarz algorithm has been proposed for online processing of data in [8, 3]. In these papers, the processing is online, so neither distributed nor parallel.

2. Analysis of the Kaczmarz Algorithm for Tree Based Distributed Systems of Equations

In this section, we will demonstrate that the Kaczmarz algorithm for tree based equations as defined in Equations (7) and (9) converges. We consider three cases separately: (i) the system is consistent and the solution is unique; (ii) the system is consistent but there are many solutions; and (iii) the system is inconsistent. In subsection 2.1 we prove that for case (i) the algorithm converges to the solution, and in subsection 2.2 we prove that for case (ii) the algorithm converges to the solution of minimal norm. Also in subsection 2.2, we introduce the relaxed version of the update in Equation (7). We prove that for every relaxation parameter \( \omega \in (0, 2) \), the algorithm converges to the solution of minimal norm.

Then in subsection 2.3, we prove that for case (iii) the algorithm converges to a generalized solution \( \tilde{x}(\omega) \) which depends on \( \omega \), and \( \tilde{x}(\omega) \) converges to a weighted least-squares solution as \( \omega \to 0 \).

2.1. Systems with Unique Solutions. For our analysis, we need to trace the estimates through the tree. Suppose that the tree has \( t \) leaves; for each leaf \( \ell \), let \( p_\ell - 1 \) denote the length of the path between the root \( r \) and the leaf \( \ell \). We will denote the vertices on the path from \( r \) to \( \ell \) by \( r = (\ell, 1), (\ell, 2), \ldots, (\ell, p_\ell) = \ell \). During the dispersion stage, we have for \( p = 2, \ldots, p_\ell \):

\[
\tilde{x}_{\ell,p}^{(n)} = \tilde{x}_{\ell,p-1}^{(n)} + \left( \frac{r_{\ell,p}(\tilde{x}_{\ell,p-1}^{(n)})}{\| \tilde{a}_{\ell,p} \|^2} \right) \tilde{a}_{\ell,p}.
\]

Then at the beginning of the pooling stage, we have the estimates \( \tilde{y}_\ell^{(n)} := \tilde{x}_\ell^{(n)} \) (we denote \( \tilde{x}_\ell^{(n)} := \tilde{x}_{\ell,p}^{(n)} \) and \( \tilde{y}_\ell^{(n)} := \tilde{y}_{\ell, p}^{(n)} \)). These estimates then pool back at the root as follows (the proof is a straightforward induction argument):
Lemma 1. The estimate at the root at the end of the pooling stage is given by:
\[
\hat{y}_r^{(n)} = \sum_{\ell \in L} w(\ell, r) y_\ell^{(n)}.
\]

Note that also by induction, we have that
\[
\sum_{\ell \in L} w(\ell, r) = 1.
\]

Theorem 2. Suppose that the equation \( Ax = \vec{b} \) has a unique solution, denoted by \( \vec{x}^S \). There exists a constant \( \alpha < 1 \), such that
\[
\| \vec{x}_S - \hat{x}_S^{(n)} \| \leq \alpha \| \vec{x}_S - \hat{x}_S^{(n)} \|.
\]
Consequently,
\[
\lim_{n \to \infty} \hat{x}_S^{(n)} = \vec{x}_S,
\]
and the convergence is linear in order.

Proof. Along any path from the root \( r \) to the leaf \( \ell \), the dispersion stage is identical to the classical Kaczmarz algorithm, and so we can write (see [13]):
\[
\vec{x}_S - \hat{x}_S^{(n)} = P_{\ell, p_\ell}(\vec{x}_S - \hat{x}_S^{(n)}) = P_{\ell, p_\ell} \ldots P_{\ell, 2} P_{\ell, 1}(\vec{x}_S - \hat{x}_S^{(n)}),
\]
from which it follows immediately that
\[
\| \vec{x}_S - \hat{x}_S^{(n)} \| \leq \| \vec{x}_S - \hat{x}_S^{(n)} \|.
\]

We claim that unless \( \vec{x}_S = \hat{x}_S^{(n)} \), we must have a strict inequality for at least one leaf, say \( \ell_0 \). Indeed, suppose to the contrary that for every leaf \( \ell \), we had equality in Equation (11), then by Equation (2.1), we must have for every vertex \( v = (\ell, k) \) in the path from the root \( r \) to the leaf \( \ell \):
\[
P_v(\vec{x}_S - \hat{x}_S^{(n)}) = \vec{x}_S - \hat{x}_S^{(n)}.
\]
Therefore, we obtain
\[
S_v(\vec{x}_S - \hat{x}_S^{(n)}) = 0 \text{ for all vertices } v.
\]
By our assumption that the equation has a unique solution, we obtain that \( \vec{x}_S - \hat{x}_S^{(n)} = 0 \).

By Equations (10) and (11) and our previous claim, we have
\[
\| \vec{x}_S - \hat{x}_S^{(n+1)} \| < \sum_{\ell \in L} w(\ell, r) \| \vec{x}_S - \hat{x}_S^{(n)} \| = \| \vec{x}_S - \hat{x}_S^{(n)} \|.
\]

By continuity and compactness, there is a uniform constant \( \alpha \) less than 1 that satisfies the claim. This completes the proof. \( \square \)

As we shall see in the sequel, we can interpret the above proof in the following way: define the mapping
\[
\mathcal{P} := \sum_{\ell \in L} w(\ell, r) P_{\ell, p_\ell} \ldots P_{\ell, 2} P_{\ell, 1},
\]
then the mapping \( \vec{z} \mapsto \vec{x}_S - \mathcal{P}(\vec{x}_S - \vec{z}) \) is a contraction with unique fixed point \( \vec{x}_S \). Moreover, the iteration of the algorithm can be expressed as:
\[
\hat{x}_S^{(n+1)} = \vec{x}_S - \mathcal{P}(\vec{x}_S - \hat{x}_S^{(n)}).
\]
2.2. Consistent Systems. We shall show in this section that the distributed Kaczmarz algorithm as defined in Equations (7) and (9) will converge to the solution with minimal norm in the case that there exists more than one solution. We first introduce the relaxed version of the algorithm; we will show that for any appropriate relaxation parameter, the relaxed algorithm will converge to the solution of minimal norm.

The relaxed distributed Kaczmarz algorithm for tree based equations is as follows. Choose a relaxation parameter \( \omega > 0 \) (generally, we will require \( \omega \in (0, 2) \), though see Section 3 for further discussion). At each node \( w \) during the dispersion stage of iteration \( n \), the update becomes:

\[
\vec{x}_w^{(n)} = \vec{x}_v^{(n)} + \omega \frac{T_w(\vec{x}_v^{(n)})}{\|\vec{a}_w\|^2} \vec{a}_w.
\]

We suppress the dependence of \( \vec{x}_v^{(n)} \) on \( \omega \), but we will consider the limit

\[
\lim_{n \to \infty} \vec{x}_v^{(n)} := \vec{x}(\omega)
\]

which (in general) depends on \( \omega \). We will prove in Theorem 4 that when the system of equations is consistent, then this limit exists and is in fact independent of \( \omega \). We will prove in Theorem 14 that when the system of equations is inconsistent, then the limit exists, depends on \( \omega \), and \( \vec{x}(\omega) \to \vec{x}^{LS} \) as \( \omega \to 0 \), where \( \vec{x}^{LS} \) is a weighted least-squares solution.

As in Equations (3) and (4), we use \( P_v \) and \( Q_v \) to denote the linear and affine projections, respectively. We will need the fact that \( Q_v \) is Lipschitz with constant 1:

\[
\|Q_v \vec{z}_1 - Q_v \vec{z}_2\| \leq \|\vec{z}_1 - \vec{z}_2\|.
\]

The relaxed Kaczmarz update in Equation (16) can be expressed as:

\[
\vec{x}_w^{(n)} = [(1 - \omega)I + \omega Q_w] \vec{x}_v^{(n)} := Q_w^\omega \vec{x}_v^{(n)}.
\]

Thus, the estimate \( \vec{x}_\ell^{(n)} \) of the solution at leaf \( \ell \), given the solution estimate \( \vec{x}^{(n)} \) as input at the root \( r \), is:

\[
\vec{x}_\ell^{(n)} = Q_{\ell, p_1}^\omega \cdots Q_{\ell, p_2}^\omega Q_{\ell, 1}^\omega \vec{x}^{(n)} := Q_\ell^\omega \vec{x}^{(n)}.
\]

We can now write the full update, with both dispersion and pooling stages, of the relaxed Kaczmarz algorithm as:

\[
\vec{x}^{(n+1)} = \sum_{\ell \in \mathcal{L}} w(\ell, r) Q_\ell^\omega \vec{x}^{(n)} := Q^\omega \vec{x}^{(n)}.
\]

We note that, as above, each \( Q_\ell^\omega \) is a Lipschitz map with constant 1 whenever \( 0 < \omega < 1 \), but in fact, since \( Q_v \vec{z}_1 - Q_v \vec{z}_2 = P_v \vec{z}_1 - P_v \vec{z}_2 \), we have that \( Q_v^\omega \) is Lipschitz with constant 1 whenever \( 0 < \omega < 2 \). Moreover, as \( \sum_{\ell \in \mathcal{L}} w(\ell, r) = 1 \), we obtain:

**Lemma 3.** For \( 0 < \omega < 2 \), \( Q_\ell^\omega \) and \( Q^\omega \) are Lipschitz with constant 1.
We note that the mappings $Q^{(i)}_{Q^{(j)}}$, $Q^{(i)}_{Q^{(j)}}$ are affine transformations; we also have use for the analogous linear transformations. Similar to Equations (18) and (19), we write

\[ P_{\omega} := (1 - \omega)I + \omega P_v; \]
\[ P_{\omega}^\ell := P_{\omega}^{\ell,p} \cdots P_{\omega}^{\ell,2} P_{\omega}^{\ell,1}; \]
\[ P_{\omega} := \sum_{\ell \in \mathcal{L}} w(\ell, r) P_{\omega}^\ell. \]

**Theorem 4.** If the system of equations given by $A\vec{x} = \vec{b}$ is consistent, then for any $0 < \omega < 2$, the sequence of estimates $\vec{x}^{(n)}$ as given in Equation (19) converges to the solution $\vec{x}^M$ of minimal norm as given by (6), provided the initial estimate $\vec{x}^{(0)} \in \mathbb{R}^{(A^*)}$.

We shall prove Theorem 4 using a sequence of lemmas. We follow the argument as presented in Natterer [14], adapting the lemmas as necessary. For completeness, we will state (without proof) the lemmas that we will use unaltered from [14]. (See also Yosida [27].)

**Lemma 5.** [14, Lemma V.3.1]. Let $T$ be a linear map on a Hilbert space $H$ with $\|T\| \leq 1$. Then,

\[ H = \mathcal{N}(I - T) \oplus \mathcal{R}(I - T). \]

**Lemma 6.** [14, Lemma V.3.2]. Suppose $\{\vec{z}^k\}$ is a sequence in $\mathbb{C}^d$ such that for any leaf $\ell \in \mathcal{L}$,

\[ \|\vec{z}^k\| \leq 1 \text{ and } \lim_{k \to \infty} \|P_{\omega}^\ell \vec{z}^k\| = 1. \]

Then for $0 < \omega < 2$, we have

\[ \lim_{k \to \infty} (I - P_{\omega}^\ell) \vec{z}^k = 0. \]

**Lemma 7.** Suppose $\{\vec{z}^k\}$ is a sequence in $\mathbb{C}^d$ such that

\[ \|\vec{z}^k\| \leq 1 \text{ and } \lim_{k \to \infty} \|P_{\omega} \vec{z}^k\| = 1, \]

then for $0 < \omega < 2$, we have

\[ \lim_{k \to \infty} (I - P_{\omega}) \vec{z}^k = 0. \]

**Proof.** Note that

\[ (I - P_{\omega}) \vec{z}^k = \sum_{\ell \in \mathcal{L}} w(\ell, r) (I - P_{\omega}^\ell) \vec{z}^k, \]

so it is sufficient to show that the hypotheses of Lemma 6 are satisfied. Since $\|P_{\omega}^\ell \vec{z}^k\| \leq 1$ and $\sum_{\ell} w(\ell, r) = 1$, we have

\[ 1 = \lim_{k \to \infty} \|P_{\omega} \vec{z}^k\| \leq \lim_{k \to \infty} \sum_{\ell \in \mathcal{L}} w(\ell, r) \|P_{\omega}^\ell \vec{z}^k\| \leq 1. \]

Thus, we must have $\lim_{k \to \infty} \|P_{\omega}^\ell \vec{z}^k\| = 1$ for every $\ell \in \mathcal{L}$. \qed

**Lemma 8.** For $0 < \omega < 2$, we have

\[ \mathcal{N}(I - P_{\omega}) = \bigcap_{v \text{ node}} \mathcal{N}(I - P_v). \]
Proof. Suppose \( P_v \vec{z} = \vec{z} \) for every node \( v \). Then
\[
\mathcal{P}^\omega \vec{z} = \sum_{\ell \in \mathcal{L}} w(\ell, r) P_{\ell, p_{\ell}}^\omega \ldots P_{\ell, 1}^\omega \vec{z} = \sum_{\ell \in \mathcal{L}} w(\ell, r) \vec{z} = \vec{z}
\]
thus the left containment follows.

Conversely, suppose that \( \mathcal{P}^\omega \vec{z} = \vec{z} \). Again, we obtain
\[
\|\vec{z}\| = \|\mathcal{P}^\omega \vec{z}\| \leq \sum_{\ell \in \mathcal{L}} w(\ell, r) \|P_{\ell, p_{\ell}}^\omega \ldots P_{\ell, 1}^\omega \vec{z}\| \leq \|\vec{z}\|
\]
which implies that
\[
P_{\ell, p_{\ell}}^\omega \ldots P_{\ell, 1}^\omega \vec{z} = \vec{z}
\]
for every leaf \( \ell \). Hence, for every \( \ell \), and every \( j = 1, \ldots, p_\ell \), \( P_{\ell, j}^\omega \vec{z} = \vec{z} \). \( \square \)

Lemma 9 ([14], Lemma V.3.5). For \( 0 < \omega < 2 \), \((\mathcal{P}^\omega)^k\) converges strongly, as \( k \to \infty \), to the orthogonal projection onto
\[
\bigcap_{v \text{ node}} \mathcal{N}(I - P_v) = \mathcal{N}(A).
\]
The proof is identical to that in [14], using Lemmas 5, 7, and 8.

Proof of Theorem 4. Let \( \vec{y} \) be any solution to the system of equations. We claim that for any \( \vec{z} \),
\[
(21) \quad \mathcal{Q}^\omega \vec{z} = \mathcal{P}^\omega (\vec{z} - \vec{y}) + \vec{y}
\]
Indeed, for any nodes \( v \) and \( w \), and consequently for any leaf \( \ell \), we have
\[
\mathcal{Q}^\omega_v \vec{z} = \vec{y} + \mathcal{P}^\omega_v (\vec{z} - \vec{y}) \\
\Rightarrow \mathcal{Q}^\omega_w \mathcal{Q}^\omega_v \vec{z} = \vec{y} + \mathcal{P}^\omega_w \mathcal{P}^\omega_v (\vec{z} - \vec{y}) \\
\Rightarrow \mathcal{Q}^\omega_\ell \vec{z} = \vec{y} + \mathcal{P}^\omega_\ell (\vec{z} - \vec{y}) \\
\Rightarrow \sum_{\ell \in \mathcal{L}} w(\ell, r) \mathcal{Q}^\omega_\ell \vec{z} = \sum_{\ell \in \mathcal{L}} w(\ell, r) (\vec{y} + \mathcal{P}^\omega_\ell (\vec{z} - \vec{y})),
\]
which demonstrates Equation (21).

Therefore, by Lemma 9, we have that for any \( \vec{z} \),
\[
(\mathcal{Q}^\omega)^k \vec{z} \to \vec{y} + Pr(\vec{z} - \vec{y}),
\]
as \( k \to \infty \), where \( Pr \) is the projection onto \( \mathcal{N}(A) \). If \( \vec{z} \in \mathcal{R}(A^*) \), we have that \( \vec{y} + Pr(\vec{z} - \vec{y}) \) is the unique solution to the system of equations that is in \( \mathcal{R}(A^*) \), and hence is the solution of minimal norm. \( \square \)

We can see that for \( \vec{z} \in \mathcal{R}(A^*) \), the convergence rate of \( (\mathcal{Q}^\omega)^k \vec{z} \to \vec{x}^M \) is linear, but we will formalize this in the next subsection (Corollary 12).
2.3. Inconsistent Equations. We now consider the case of inconsistent systems of equations. For this purpose, we must consider the relaxed version of the algorithm, as in the previous subsection. Again, we assume $0 < \omega < 2$ and consider the limit
\[
\lim_{n \to \infty} \vec{x}^{(n)} = \vec{x}(\omega).
\]
We will prove in Theorem 11 and Corollary 12 that the limit exists, but unlike in the case of consistent systems, the limit will depend on $\omega$. Moreover, we will prove in Theorem 14 that
\[
\lim_{\omega \to 0} \vec{x}(\omega) = \vec{x}^{LS}
\]
exists, and $\vec{x}^{LS}$ is a generalized solution which minimizes a weighted least-squares norm.

We follow the presentation of the analogous results for the classical Kaczmarz algorithm as presented in [14]. Indeed, we will proceed by analyzing the distributed Kaczmarz algorithm using the ideas from Successive Over-Relaxation (SOR). We need to follow the updates as they disperse through the tree, and also how the updates are pooled back at the root, and so we define the following quantities.

We begin with reindexing the equations, which are currently indexed by the nodes as $S_v(\vec{x}) = b_v$. As before, for each leaf $\ell$, we consider the path from the root $r$ to the leaf $\ell$, and index the corresponding equations as:
\[
S_{\ell,1}(\vec{x}) = b_{\ell,1}, \ldots, S_{\ell,p_{\ell}}(\vec{x}) = b_{\ell,p_{\ell}}.
\]

For each leaf $\ell$, we can define:
\[
\begin{align*}
S_\ell &= \begin{pmatrix}
S_{\ell,1} \\
S_{\ell,2} \\
\vdots \\
S_{\ell,p_{\ell}}
\end{pmatrix}, & \vec{b}_\ell &= \begin{pmatrix}
b_{\ell,1} \\
b_{\ell,2} \\
\vdots \\
b_{\ell,p_{\ell}}
\end{pmatrix}, & D_\ell &= \begin{pmatrix}
S_{\ell,1}^* & 0 & \cdots & 0 \\
0 & S_{\ell,2}^* & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & S_{\ell,p_{\ell}}^*
\end{pmatrix} \\
L_\ell &= \begin{pmatrix}
0 & 0 & \cdots & 0 & 0 \\
S_{\ell,2}^* S_{\ell,1} & 0 & \cdots & 0 & 0 \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
S_{\ell,p_{\ell}}^* S_{\ell,1} & S_{\ell,p_{\ell}}^* S_{\ell,2} & \cdots & S_{\ell,p_{\ell}}^* S_{\ell,p_{\ell}} & 0
\end{pmatrix}
\end{align*}
\]

Then from input $\vec{x}^{(n)}$ at the root of the tree, the approximation at leaf $\ell$ after the dispersion stage in iteration $n$ is given by:
\[
\vec{x}_\ell^{(n)} = \mathcal{Q}_\ell \vec{x}^{(n)} = \vec{x}^{(n)} + \sum_{j=1}^{p_\ell} S_{\ell,j}^* u_j = \vec{x}^{(n)} + S_\ell^* \vec{u},
\]
where
\[
\vec{u} := (u_1 \ldots u_{p_\ell})^T = \omega (D_\ell + \omega L_\ell)^{-1} \left( \vec{b}_\ell - S_\ell \vec{x}^{(n)} \right).
\]

Therefore, we can write
\[
\vec{x}_\ell^{(n)} = \vec{x}^{(n)} + \omega S_\ell^* (D_\ell + \omega L_\ell)^{-1} \left( \vec{b}_\ell - S_\ell \vec{x}^{(n)} \right) = (I - \omega S_\ell^* (D_\ell + \omega L_\ell)^{-1} S_\ell) \vec{x}^{(n)} + \omega S_\ell^* (D_\ell + \omega L_\ell)^{-1} \vec{b}_\ell.
\]
Combining these approximations back at the root yields:

\[ \vec{x}^{(n+1)} = \sum_{\ell \in \mathcal{L}} w(\ell, r) \vec{x}_\ell^{(n)} \]

\[ = \sum_{\ell \in \mathcal{L}} w(\ell, r) \left( I - \omega S^*_\ell (D_\ell + \omega L_\ell)^{-1} S_\ell \right) \vec{x}^{(n)} + \omega \sum_{\ell \in \mathcal{L}} w(\ell, r) S^*_\ell (D_\ell + \omega L_\ell)^{-1} \vec{b}_\ell \]

\[ = \left( I - \omega \sum_{\ell \in \mathcal{L}} w(\ell, r) S^*_\ell (D_\ell + \omega L_\ell)^{-1} S_\ell \right) \vec{x}^{(n)} + \omega \sum_{\ell \in \mathcal{L}} w(\ell, r) S^*_\ell (D_\ell + \omega L_\ell)^{-1} \vec{b}_\ell. \]  

(22)

We write

\[ \vec{x}^{(n+1)} = \sum_{\ell \in \mathcal{L}} w(\ell, r) B^\omega_\ell \vec{x}^{(n)} + \sum_{\ell \in \mathcal{L}} w(\ell, r) \vec{b}^\omega_\ell \]

where

\[ B^\omega_\ell := I - \omega S^*_\ell (D_\ell + \omega L_\ell)^{-1} S_\ell; \quad \vec{b}^\omega_\ell := \omega S^*_\ell (D_\ell + \omega L_\ell)^{-1} \vec{b}_\ell. \]

Written in this form, for each leaf \( \ell \), the input at the root undergoes the linearly ordered Kaczmarz algorithm. So, if the input at the root is \( \vec{x}^{(n)} \), then the estimate at leaf \( \ell \) is:

\[ \vec{x}^{(n)} = Q^\omega_\ell \vec{x}^{(n)} = B^\omega_\ell \vec{x}^{(n)} + \vec{b}^\omega_\ell. \]

As we shall see, for each leaf \( \ell \) and \( \omega \in (0, 2) \), \( B^\omega_\ell \) has operator norm bounded by 1, and the eigenvalues are either 1 or strictly less than 1 in magnitude. We state these formally in Lemma 10.

We enumerate the leaves of the tree as \( \ell_1, \ldots, \ell_t \), and write:

\[ S = \begin{pmatrix} S_{\ell_1} & \cdots & S_{\ell_t} \end{pmatrix} \quad \vec{b} = \begin{pmatrix} \vec{b}_{\ell_1} \\ \vdots \\ \vec{b}_{\ell_t} \end{pmatrix} \]

The system of equations \( A \vec{x} = \vec{b} \) becomes:

(24)  

\[ S \vec{x} = \vec{b} \]

where many of the equations are now repeated in Equation (24). However, we have \( \mathcal{N}(S) = \mathcal{N}(A) \) and \( \mathcal{R}(S^*) = \mathcal{R}(A^*) \).

We also write

\[ D := \begin{pmatrix} D_{\ell_1} & 0 & \cdots & 0 \\ 0 & D_{\ell_2} & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & D_{\ell_t} \end{pmatrix} \quad L := \begin{pmatrix} L_{\ell_1} & 0 & \cdots & 0 \\ 0 & L_{\ell_2} & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & L_{\ell_t} \end{pmatrix} \]

so

(25)  

\[ (D + \omega L)^{-1} = \begin{pmatrix} (D_{\ell_1} + \omega L_{\ell_1})^{-1} & 0 & \cdots & 0 \\ 0 & (D_{\ell_2} + \omega L_{\ell_2})^{-1} & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & (D_{\ell_t} + \omega L_{\ell_t})^{-1} \end{pmatrix} \]
We also define

\begin{equation}
W = \begin{pmatrix}
    w(\ell_1, r)I_{p_{\ell_1}} & 0 & \ldots & 0 \\
    0 & w(\ell_2, r)I_{p_{\ell_2}} & \ldots & 0 \\
    \vdots & \vdots & \ddots & \vdots \\
    0 & 0 & \ldots & w(\ell_t, r)I_{p_{\ell_t}}
\end{pmatrix}
\end{equation}

Note that since $D + \omega L$ and $W$ are block matrices with blocks of the same size, and in $W$ the blocks are scalar multiples of the identity, we have that the two matrices commute:

\begin{equation}
(D + \omega L)^{-1} W = W (D + \omega L)^{-1} = W^{1/2} (D + \omega L)^{-1} W^{1/2}.
\end{equation}

We can therefore write Equation (22) as

\begin{equation}
\vec{x}^{(n+1)} = (I - \omega S^* (D + \omega L)^{-1} WS) \vec{x}^{(n)} + \omega S^* (D + \omega L)^{-1} W \vec{b}.
\end{equation}

Note that $R(S^*)$ is an invariant subspace for $B^\omega$, and that $\vec{b}^\omega \in R(S^*)$. We let $\vec{b}^\omega$ denote the restriction of $B^\omega$ to the subspace $R(S^*)$. As we shall see, provided the input $\vec{x}^0 \in R(S^*)$, the sequence $\vec{x}^k$ converges. In fact, we will show that the transformation $\vec{b}^\omega$ is a contraction, and since $\vec{b}^\omega \in R(S^*)$, then the mapping

$$\vec{z} \mapsto \vec{b}^\omega \vec{z} + \vec{b}^\omega$$

has a unique fixed point within $R(S^*)$. We shall do so via a series of lemmas.

**Lemma 10.** For each leaf $\ell$ and for $\omega \in (0, 2)$, $B^\omega_\ell$ is Lipschitz continuous with constant at most 1 (i.e. it has operator norm at most 1). Consequently, $\vec{b}^\omega$ is also Lipschitz continuous with constant at most 1.

Moreover, for each leaf $\ell$ and $\omega \in (0, 2)$, if $\lambda$ is an eigenvalue of $B^\omega_\ell$ with $|\lambda| = 1$, then $\lambda = 1$. Consequently, any eigenvalue $\lambda \neq 1$ has the property $|\lambda| < 1$.

**Proof.** For input $\vec{z}_i$, we have that

$$Q^\omega_\ell \vec{z}_i = B^\omega_\ell \vec{z}_i + \vec{b}^\omega_\ell,$$

hence

$$\|B^\omega_\ell \vec{z}_1 - B^\omega_\ell \vec{z}_2\| = \|Q^\omega_\ell \vec{z}_1 - Q^\omega_\ell \vec{z}_2\| \leq \|\vec{z}_1 - \vec{z}_2\|$$

by Lemma 3. Since $B^\omega_\ell$ is a convex combination of the $B^\omega_0$, it also has Lipschitz constant at most 1. The last conclusion follows from [14, Lemma V.3.9].

**Theorem 11.** The spectral radius of $\vec{b}^\omega$ is strictly less than 1.

**Proof.** For each leaf $\ell$, Lemma 10 implies that

\begin{equation}
\|B^\omega_\ell\| \leq 1, \quad |\langle B^\omega_\ell \vec{v}, \vec{v}\rangle| \leq \|\vec{v}\|^2.
\end{equation}

Let $\lambda$ be an eigenvalue for $\vec{b}^\omega$. We must have $\lambda \neq 1$; if it were not so, then there exists a nonzero $\vec{v} \in R(S^*)$ with $\vec{b}^\omega \vec{v} = \vec{v}$. However, by Lemma 8 we must have $\vec{z} \in N(A) = N(S)$ which is a contradiction. Let $\vec{v}$ be a unit norm eigenvector for $\lambda$. We have

$$|\lambda| = |\langle \vec{b}^\omega \vec{v}, \vec{v}\rangle| \leq \sum_{\ell \in L} w(\ell, r)|\langle B^\omega_\ell \vec{v}, \vec{v}\rangle| \leq 1.$$
Now suppose that $|\lambda| = 1$, then we similarly obtain

\begin{equation}
\lambda = \sum_{\ell \in L} \langle B_\ell^\omega \vec{v}, \vec{v} \rangle
\end{equation}

from which we deduce that the argument of the complex number $\langle B_\ell^\omega \vec{v}, \vec{v} \rangle$ is independent of the leaf $\ell$. Therefore, we must have for every leaf $\ell$

\begin{equation}
\langle B_\ell^\omega \vec{v}, \vec{v} \rangle = \lambda.
\end{equation}

However, we know by the Cauchy-Schwarz inequality that equality in Equation (31) can only occur when $(\vec{v}, \lambda)$ is an eigenvector/eigenvalue pair for $B_\ell^\omega$. However, Lemma 10 implies that none of the leaves $\ell$ have the property that $\lambda$ is an eigenvalue, so we have arrived at a contradiction. □

**Corollary 12.** For $\omega \in (0, 2)$ and for any initial input $\vec{x}(0) \in \mathcal{R}(S^*)$, we have that the sequence given by

\begin{equation}
\vec{x}(n+1) = \tilde{B}^\omega \vec{x}(n) + \vec{b}^\omega
\end{equation}

converges to a unique point in $\mathcal{R}(S^*)$, independent of $\vec{x}(0)$, and the convergence rate is linear.

The following can be found in [14, Theorem IV.1.1]:

**Lemma 13.** For each $\omega \in (0, 2)$, let

\begin{equation}
\vec{x}(\omega) = \lim_{n \to \infty} \vec{x}(n)
\end{equation}

where $\vec{x}(n)$ are as in Equation (32). Then, $\vec{x}(\omega)$ is the unique vector that satisfies the conditions

\begin{equation}
S^* (D + \omega L)^{-1} \mathcal{W} \left( \vec{b} - S \vec{z} \right) = 0; \quad \vec{z} \in \mathcal{R}(S^*).
\end{equation}

**Theorem 14.** For each $\omega \in (0, 2)$, let

\begin{equation}
\vec{x}(\omega) = \lim_{n \to \infty} \vec{x}(n)
\end{equation}

as in Equation (33). Then,

\begin{equation}
\lim_{\omega \to 0} \vec{x}(\omega) = \vec{x}^{LS}
\end{equation}

where $\vec{x}^{LS}$ minimizes the functional

\begin{equation}
\vec{z} \mapsto \langle D^{-1} \mathcal{W} (\vec{b} - S \vec{z}), (\vec{b} - S \vec{z}) \rangle.
\end{equation}

**Proof.** Let $\vec{x}^{LS}$ be the unique vector that satisfies the conditions

\begin{equation}
S^* D^{-1} \mathcal{W} \left( \vec{b} - S \vec{x}^{LS} \right) = 0; \quad \vec{x}^{LS} \in \mathcal{R}(S^*).
\end{equation}

We have that $\vec{x}(\omega)$, as the unique solution of Equation (33) and $\vec{x}^{LS}$, as the unique solution of Equation (35), satisfy

\[
\vec{x}(\omega) = \vec{x}^{LS} + 0(\omega).
\]

Indeed, this follows from the fact that $(D + \omega L)^{-1} \to D^{-1}$ as $\omega \to 0$, together with the fact that $\vec{x}(\omega), \vec{x}^{LS} \in \mathcal{R}(S^*)$. □
We can re-write Equation (34) in the following way:
\[(36) \quad \vec{z} \mapsto \langle D^{-1}V(\vec{b} - A\vec{z}), (\vec{b} - A\vec{z}) \rangle \]
where \(D\) is the diagonal matrix with entries given by \(\|\vec{a}_v\|^2\), and \(V\) is the diagonal matrix whose entry for node \(v\) is given by:
\[V_{vv} = \sum_{\ell \in \mathcal{L} \mid \ell < v} w(\ell, r).\]

Remark 1. As we mentioned in our discussion of related work, we can view the Kaczmarz algorithm that we have defined for tree-based data as a distributed optimization problem. In this view, the objective function is given by Equation (36). We emphasize here that, unlike existing distributed gradient descent algorithms [15, 28], we are able to establish convergence without the strong convexity assumption. Indeed, in the case of real data, the Hessian of our objective function is \(A^* D^{-1} VA\), which is nonnegative but need not be strictly positive. Moreover, our convergence guarantee is valid in the complex case.

2.4. Distributed Solutions. For each node \(v\) in the tree, the sequence of approximations \(\vec{x}_v^{(n)}\) and \(\vec{y}_v^{(n)}\) will have a limit, i.e. the following limits exist:
\[(37) \quad \lim_{n \to \infty} \vec{x}_v^{(n)} = \vec{x}_v; \quad \lim_{n \to \infty} \vec{y}_v^{(n)} = \vec{y}_v.\]
In the relaxed case, these limits may depend on the relaxation parameter \(\omega\); if so we will denote this dependence by \(\vec{x}_v(\omega)\) and \(\vec{y}_v(\omega)\).

Corollary 15. If the system of equations \(A\vec{x} = \vec{b}\) is consistent, then for every node \(v\) and every \(\omega \in (0, 2)\), the limits \(\vec{x}_v\) and \(\vec{y}_v\) as in Equation (37) equal \(\vec{x}^M\), the solution of minimal norm.

Proof. We have by Theorem 4 that \(\vec{x}(\omega) = \vec{x}^M\) for every \(\omega \in (0, 2)\). For a node \(v\), let the path from the root \(r\) to \(v\) be denoted by \(r = (v, 1), \ldots, (v, p_v) = v\), where \(p_v - 1\) is the length of the path. Then, we have that
\[\lim_{n \to \infty} \vec{x}_v^{(n)} = \lim_{n \to \infty} Q_{v,p_v}^\omega \cdots Q_{v,1}^\omega \vec{x}^{(n)} = Q_{v,p_v}^\omega \cdots Q_{v,1}^\omega \vec{x}(\omega) = \vec{x}^M.\]
This holds as a consequence of the fact that any solution to the system of equations is fixed by \(Q_v^\omega\).

Since we have that \(\vec{y}_v^{(n)}\) is a convex combination of the vectors \(\vec{x}_v^{(n)}\), which all converge to \(\vec{x}(\omega)\), we have that \(\vec{y}_v = \vec{x}^M\) also. \(\square\)

Corollary 16. If the system of equations \(A\vec{x} = \vec{b}\) is inconsistent, then for every node \(v\) and every \(\omega \in (0, 2)\), the limits \(\vec{x}_v\) and \(\vec{y}_v\) as in Equation (37) exist and depend on \(\omega\). Moreover, we have
\[\lim_{\omega \to 0} \vec{x}_v(\omega) = \vec{x}^{LS}; \quad \lim_{\omega \to 0} \vec{y}_v(\omega) = \vec{x}^{LS},\]
where \(\vec{x}^{LS}\) is the vector as in Theorem 14.

Proof. We apply the SOR analysis of \(\vec{x}_v^{(n)} = Q_{(v,p_v)}^\omega \cdots Q_{(v,1)}^\omega \vec{x}^{(n)}\) with input \(\vec{x}^{(n)}\) to obtain
\[\vec{x}_v^{(n)} = B_v^\omega \vec{x}^{(n)} + \vec{b}_v^\omega\]
where $\mathcal{B}_v^\omega$ and $\mathcal{b}_v^\omega$ are analogous to those in Equation (23). Taking limits on $n$, we obtain

$$\bar{x}_v(\omega) = \mathcal{B}_v^\omega \bar{x}(\omega) + \mathcal{b}_v^\omega.$$ 

Since, as $\omega \to 0$, we have that $\mathcal{B}_v^\omega \to I$, $\mathcal{b}_v^\omega \to 0$, and $\bar{x}(\omega) \to \bar{x}^{LS}$, we obtain

$$\lim_{\omega \to 0} \bar{x}_v(\omega) = \bar{x}^{LS}.$$ 

As previously, $\bar{y}_v(\omega)$ is a convex combination of $\bar{x}_v(\omega)$, so $\bar{y}_v(\omega) \to \bar{x}^{LS}$ as $\omega \to 0$.

2.5. Error Analysis. We consider the question of how errors propagate through the iterations of the dispersion and pooling stages. We model errors as additive; the sources of errors could be machine errors, transmission errors, errors from compression to reduce communications of the dispersion and pooling stages. We model errors as additive; the sources of errors

$$\bar{x}_v(\omega) = \mathcal{B}_v^\omega \bar{x}(\omega) + \mathcal{b}_v^\omega.$$ 

Here, $\bar{x}_v(\omega)$ and $\bar{y}_v(\omega)$ are the error-ridden estimates which are passed to the successor (or predecessor) nodes in the dispersion (or pooling) stage, respectively, with additive errors $\bar{e}_v$ and $\bar{d}_v$. We trace the errors during the dispersion stage as follows: for vertex $v$ on a path between the root $r$ and leaf $\ell$, and the path parameterized by $r = (\ell, 1), \ldots, (\ell, p_\ell) = \ell$, suppose that $v = (\ell, k)$. Then, the error introduced at vertex $v$ (with errors introduced at no other vertex) results in the estimate

$$\bar{x}_v(\omega) = Q_\ell^\omega \cdots Q_{\ell,k+1}^\omega \left( \bar{x}_v(\omega) + e_v(\omega) \right)$$

$$\bar{x}_v(\omega) = Q_\ell^\omega \cdots Q_{\ell,k+1}^\omega \left( \bar{x}_v(\omega) + e_v(\omega) \right)$$

Equation (39) follows for some $e_v(\omega)$ since the $Q_\ell^\omega$ are affine transformations. We have that

$$\|e_v(\omega)\| = \|Q_\ell^\omega \cdots Q_{\ell,k+1}^\omega \left( \bar{x}_v(\omega) + e_v(\omega) \right) - Q_\ell^\omega \cdots Q_{\ell,k+1}^\omega \left( \bar{x}_v(\omega) \right)\| \leq \|e_v(\omega)\|$$

since the $Q_\ell^\omega$ have Lipschitz constant 1. The additive errors $\delta_v(\omega)$ simply sum in the pooling stage, and thus we calculate the total errors from iteration $n$ to iteration $n + 1$.

Lemma 17. Suppose we have additive errors as in Equation (38) introduced in iteration $n$. Suppose no errors were introduced in previous iterations. Then the estimate after iteration $n$ is:

$$\bar{x}_{e+1} = \bar{x}_{e+1} + \sum_v \sum_{\ell \in \mathcal{L}} w(\ell, r) \bar{e}_v(\omega) + \sum_v w(\ell, r) \delta_{v,e}(\omega).$$

The magnitude of the error is bounded by:

$$\|\bar{x}_{e+1} - \bar{x}_{e+1}\| \leq K \max \{\|\bar{e}_v(\omega)\|, \|\delta_{v,e}(\omega)\|\}$$

where $K$ is 2 times the depth of the tree.

We write

$$E^{(n)} = \sum_v \sum_{\ell \in \mathcal{L}} w(\ell, r) \bar{e}_v(\omega) + \sum_v w(\ell, r) \delta_{v,e}(\omega).$$
Theorem 18. If the additive errors in Equation (38) are uniformly bounded by $M$, and the system of equations $A\tilde{x} = \tilde{b}$ has a unique solution. Then the sequence of approximations $\{\tilde{x}^{(n)}_e\}$ has the property that

\[
\limsup_{n \to \infty} \|\tilde{x}(\omega) - \tilde{x}^{(n)}_e\| \leq \frac{2KM}{1 - \rho(B^{\omega})}
\]

where $K$ is the depth of the tree.

Proof. We have

\[
\tilde{x}^{(n)}_e = \tilde{x}^{(n)} + \sum_{k=1}^{n} (B^{\omega})^{n-k} E^{(k)}.
\]

As noted previously, $\|E^{(k)}\| \leq 2KM$, and if $A\tilde{x} = \tilde{b}$ has a unique solution, then $\rho(B^{\omega}) < 1$ (see proof of Theorem 2).

Thus, for any matrix norm $\|\cdot\|$ with $\rho(B^{\omega}) < \|B^{\omega}\|$,

\[
\|\tilde{x}^{(n)} - \tilde{x}^{(n)}_e\| \leq \sum_{k=0}^{n-1} 2KM\|B^{\omega}\|^k
\]

from which Equation (43) follows. \qed

If the system of equations does not have a unique solution, then the mapping $B^{\omega}$ has 1 as an eigenvalue, and so the parts of the errors that lie in that eigenspace accumulate. Hence, no stability result is possible in this case.

2.6. Extensions. We present several possible extensions and variations that require only minor modifications to the proofs of Theorems 2, 4, and 14.

The first variation is when the nodes of the tree contain more than one equation from $A\tilde{x} = \tilde{b}$. This can be easily modeled under the assumption that each node proceeds through its equations in some a priori fixed linear ordering, and subsequently in the tree replacing each node with a path. Again, the SOR analysis passes through unaltered. Alternatives to fixed linear orderings in this situation will not be considered here.

The second variation is when the data for each node consists of linear transformations $T_v : H \to H_v$ rather than linear functionals $S_v : H \to \mathbb{C}$. If we assume that at each node, $T_v$ is onto [14], then again the SOR analysis passes through unaltered, and so we will not consider this variation further here.

The third variation is to perform the Kaczmarz update during the pooling stage of the iteration. This variation, however, requires more than minor modifications to the proofs, and will thus be considered elsewhere.

3. Implementation and Examples

For the standard Kaczmarz algorithm, it is well known that the method converges if and only if the relaxation parameter $\omega$ is in the interval $(0, 2)$. For our distributed Kaczmarz, the situation is not nearly as clear. The proofs of Theorems 3 and 14 require that $\omega \in (0, 2)$, but in numerical experiments, convergence occurred for $\omega \in (0, \Omega)$ for some $\Omega \geq 2$. The largest $\Omega$ observed was around 3.8. The precise upper limit depends on the equations themselves. In this section, we perform a preliminary analysis of the computation of $\Omega$ and the optimal $\omega_{opt}$ for a very simple setup, and give numerical results for several examples.
3.1. Examples.

Example 1. We consider the matrix
\[ A = \begin{pmatrix} -\sin \alpha & \cos \alpha \\ 0 & 1 \end{pmatrix}. \]

In geometric terms, the Kaczmarz method for this example corresponds to projection onto the x-axis and onto a line forming an angle \( \alpha \) with the x-axis.

For standard Kaczmarz, the iteration matrix is
\[ B_\omega = I - \omega A^* (D + \omega L)^{-1} A = \begin{pmatrix} 1 - \omega \sin^2 \alpha & \omega \sin \alpha \cos \alpha \\ \omega (1 - \omega) \sin \alpha \cos \alpha & (1 - \omega)(1 - \omega \cos^2 \alpha) \end{pmatrix}. \]

The eigenvalues are
\[ \lambda = \left[ \frac{\omega^2 \cos^2 \alpha}{2} + (1 - \omega) \right] \pm \omega \cos \alpha \sqrt{(\omega - 2)^2 - \omega^2 \sin^2 \alpha}. \]

For small \( \omega \), the eigenvalues are real and decreasing as a function of \( \omega \). They become complex at
\[ \omega_{\text{opt}} = \frac{2}{1 + \sin \alpha}, \]
which is between 1 and 2. After that point, both eigenvalues have magnitude \( \omega - 1 \), and the spectral radius increases in a straight line. The dependence of \( \rho \) on \( \omega \) is illustrated below in the left half of fig. 4. Here \( \alpha = \pi/3 \), \( \omega_{\text{opt}} \approx 0.10718 \), \( \rho_{\text{opt}} \approx 0.0718. \)

As pointed out in [14], there is a strong connection between the classical Kaczmarz method and Successive Over-Relaxation (SOR). In SOR the relationship between \( \omega \) and \( \rho \) shows the same type of behavior.

The example with two equations is too small to implement as distributed Kaczmarz, but we consider something similar. We project the same \( \vec{x}^{(n)} \) onto each line, and average the result to get \( \vec{x}^{(n+1)} \). We will refer to this as the averaged Kaczmarz method.

The iteration matrix is
\[ B_\omega = \begin{pmatrix} 1 - \frac{\omega}{2} \sin^2 \alpha & \frac{\omega}{2} \sin \alpha \cos \alpha \\ \frac{\omega}{2} \sin \alpha \cos \alpha & \frac{\omega}{2} \sin^2 \alpha - \omega + 1 \end{pmatrix}. \]

The eigenvalues here are always real and vary linearly with \( \omega \), namely
\[ \lambda_{1,2} = 1 + \frac{\omega}{2} (\pm \cos \alpha - 1). \]

They both have the value 1 at \( \omega = 0 \), and are both decreasing with increasing \( \omega \). The first one reaches \((-1)\) at
\[ \Omega = \frac{4}{1 + \cos \alpha}. \]

Thus, the upper limit \( \Omega \) is somewhere between 2 and 4, depending on \( \alpha \). In numerical experiments with the distributed Kaczmarz method for larger matrices, we have observed \( \Omega \) near 4, but never above 4. We conjecture that \( \Omega \) can never be larger than 4.

The minimum spectral radius occurs at \( \omega_{\text{opt}} = 2 \), independent of \( \alpha \), with \( \rho_{\text{opt}} = \cos \alpha \). The dependence of \( \rho \) on \( \omega \) is illustrated below in the left half of fig. 4. In this example, the graph for the averaged Kaczmarz method consists of two line segments, with \( \omega_{\text{opt}} = 2, \rho_{\text{opt}} = 0.5 \).

Figure 3 illustrates the optimal \( \omega \) for \( \alpha = \pi/2 \). The optimal \( \omega \) for standard Kaczmarz is \( \omega = 1 \), with \( \rho = 0 \). Convergence occurs in a single step. For the averaged method, the
optimal $\omega$ is 2, where again convergence occurs in a single step. The averaged method would still converge for a range of $\omega > 2$.

**Figure 3.** Example 1 with $\alpha = \pi/2$. The pictures show one step of standard Kaczmarz with $\omega = 1$, and one step of averaged Kaczmarz for $\omega = 1$ and $\omega = 2$. This illustrates the need for a larger $\omega$ in the averaged Kaczmarz method.

Numerical experiments with larger sets of equations indicate that the optimal $\omega$ for classical Kaczmarz is usually larger than 1, but of course cannot exceed 2. The optimal $\omega$ for distributed Kaczmarz is usually larger than 2, sometimes even approaching 4.

**Example 2.** We used a random matrix of size $8 \times 8$, with entries generated using a standard normal distribution. For the distributed Kaczmarz method, we used the 8-node graph as shown on the right in Figure 5.

For the standard Kaczmarz method, the optimal relaxation parameter was $\omega_{opt} \approx 1.7354$, with spectral radius $\rho_{opt} \approx 0.93147$. For the distributed Kaczmarz method, the results were $\omega_{opt} \approx 3.7888$, with spectral radius $\rho_{opt} \approx 0.99087$. This is illustrated in on the right in figure 4.

**Figure 4.** Dependence of the spectral radius $\rho$ of the iteration matrix on the relaxation parameter $\omega$. The left graph shows example 1 with $\alpha = \pi/3$. The right graph shows example 2.
3.2. **Implementation.** The implementation of the distributed Kaczmarz algorithm is based on the Matlab Graph Theory toolbox. This toolbox provides support for standard graphs and directed graphs (digraphs), weighted or unweighted. We are using a weighted digraph. The graph is defined by specifying the edges, which automatically also defines the nodes. Specifying nodes is only necessary if there are additional isolated nodes. Both nodes and edges can have additional properties attached to them. We take advantage of that by storing the equations and right-hand sides, as well as the current approximate solution, in the nodes. The weights are stored in the edges. We are currently only considering tree-structured graphs. One node is the root. Each node other than the root has one incoming edge, coming from the predecessor, and zero or more outgoing edges leading to the successors. A node without a successor is called a *leaf*.

The basic Kaczmarz step has the form \( x_{\text{new}} = \text{update node}(\text{node}, \omega, x) \). The graph itself is a global data structure, accessible to all subroutines; it would be very inefficient to pass it as an argument every time.

The \texttt{update node} routine does the following:

- Use the equation(s) in the node to update \( x \)
- Execute the \texttt{update node} routine for each successor node
- Combine the results into a new \( x \), using the weights stored in the outgoing edges
- Return \( x_{\text{new}} \)

This routine needs to be called only once per iteration, for the root. It will traverse the entire tree recursively.

3.3. **Numerical Experiments.** We illustrate the methods with some simple numerical experiments. All experiments were run with three different nonsingular matrices each, of sizes \( 3 \times 3 \) and \( 8 \times 8 \). All matrices were randomly generated once, and then stored. The right-hand size vectors are also random, and scaled so that the true solution has \( L^2 \)-norm 1. The test matrices are

- An almost orthogonal matrix, generated from a random orthogonal matrix by truncating to one decimal of accuracy
- A random matrix, based on a standard normal distribution
- A random matrix, based on a uniform distribution in \([-1, 1]\]

In each case, we used the optimal \( \omega \), based on minimizing the spectral radius of the iteration matrix numerically. The distributed Kaczmarz method used the graphs shown in Figure 1.

Results are shown in Tables 1 and 2. In all cases, we start with \( x_0 = 0 \), so the initial \( L^2 \)-error is \( e_0 = 1 \). \( e_{10} \) refers to the error after 10 iteration steps. For an orthogonal matrix, the standard Kaczmarz method converges in a single step. It is not surprising that it performs extremely well for the almost orthogonal matrices.

|                  | Standard Kaczmarz | Distributed Kaczmarz |
|------------------|-------------------|----------------------|
|                  | \( \omega_{\text{opt}} \) | \( \rho_{\text{opt}} \) | \( e_{10} \) | \( \omega_{\text{opt}} \) | \( \rho_{\text{opt}} \) | \( e_{10} \) |
| orthogonal       | 1.00030           | 0.00294              | 0          | 1.33833           | 0.33753              | 1.5974 \cdot 10^{-5} |
| normal           | 1.07213           | 0.20188              | 1.2793 \cdot 10^{-6} | 1.82299           | 0.29611              | 7.2461 \cdot 10^{-6} |
| uniform          | 1.18634           | 0.37073              | 9.0922 \cdot 10^{-4} | 1.92714           | 0.82562              | 1.49608 \cdot 10^{-1} |

**Table 1.** Numerical results for a \( 3 \times 3 \) system of equations.
Figure 5. The two graphs used in numerical experiments with the distributed Kaczmarz method.

|                      | Standard Kaczmarz | Distributed Kaczmarz |
|----------------------|-------------------|----------------------|
|                      | $\omega_{opt}$    | $\rho_{opt}$        | $\epsilon_{10}$    |
| orthogonal           | 1.01585           | 0.04931             | $1.53 \cdot 10^{-13}$ |
| normal               | 1.73543           | 0.93147             | $8.5663 \cdot 10^{-1}$ |
| uniform              | 1.88188           | 0.92070             | $7.1463 \cdot 10^{-1}$ |

Table 2. Numerical results for an $8 \times 8$ system of equations.
