Abstract The peanut rich in oleic acid in seed oil, also known as high oleic peanut, renders its products superior in human healthy diet, long shelf life and high oxidative stability in food and oil processing. High oleic peanut varieties in China are derived from a handful of high oleic donors with limited genetic background. Improvement of high oleic peanut cultivars by integrating key target traits is crucial for both food security and germplasm enhancement. Several superior high oleic peanut lines have been developed by marker assisted backcrossing in our breeding program. The objective of present study is to characterize bacterial wilt disease resistance and yield related traits in these novel peanut lines. The two-year disease nursery survival rates were used as an indicator for bacterial wilt resistance, and the diagnostic markers identified by QTL mapping were used for molecular verification. Genetic background of high oleic peanut lines was estimated by 40 K genotyping by target sequencing (GBTS) SNP panel. Preliminary and regional yield tests were performed for selected breeding lines in 2021. As a result, an elite high oleic peanut accession Yuhua183 was identified, inheriting the superior characteristics of its recurrent parent such as resistance to bacterial wilt, high shelling percentage and early maturity. The development of Yuhua183 broadened the genetic background of high oleic peanut germplasm, providing valuable genetic resources for peanut breeding and further utilization.

Introduction

Peanut (Arachis hypogaea L.) is a valuable source of plant protein and edible oil worldwide. It is grown in more than 100 countries, with India and
China ranking first in acreage and production, respectively (FAOSTAT 2020 https://www.fao.org/faostat/en/#home). Peanut oil is composed of eight fatty acids, namely palmitic acid (C16:0), stearic acid (C18:0), oleic acid (C18:1), linoleic acid (C18:2), behenic acid (C22:0), arachidic acid (C20:0), gadoleic acid (C20:1) and lignoceric acid (C24:0), of which oleic acid and linoleic acid account for approximately 80% of the total fatty acids (Shasidhar el al. 2017). The ratio of oleic acid and linoleic acid determines the quality of peanut oil. As unsaturated fatty acids, both oleic and linoleic acids are capable of lowering cholesterols and the risks of cardiovascular diseases. Linoleic acid encompasses one more reactive double bond than oleic acid, and is hence more prone to oxidation compared to oleic acid. Therefore, high oleic peanut oil is preferred in food industry because of chemical stability and long shelf life (Talcott et al. 2005a, b).

The direct conversion of oleic acid to linoleic acid was catalyzed by omega-6 fatty acid desaturase (namely FAD2) in seed oil of peanut (Ray et al. 1993; Lopez et al. 2001). Typically, the amount of oleic acid in peanut kernels ranges from 48 to 54%. A peanut mutant line F435, with the amount of oleic acid reaching 80%, was reported in 1987 (Norden et al. 1987). Mutations in FAD2, including single nucleotide substitution on chromosome A09 and nucleotide insertion on chromosome B09, result in marked attenuation in FAD2 activity and increased proportion of oleic acid at the expense of linoleic acid in F435 seed oil (Jung et al. 2000a, b). Consequently, a series of high oleic peanut cultivars were developed by using F435 as high oleic donor parent.

In the three decades of high oleic breeding in peanut, desirable traits such as disease resistance have been integrated in high oleic peanuts by marker assisted selection (Holbrook et al. 2017; Deshmukh et al. 2020). To facilitate the broadening of genetic background in high oleic peanut, we developed 34 advanced high oleic breeding lines by FAD2 marker assisted backcrossing (MABC) using high yielding, disease resistant and early matured elite peanut cultivars as recurrent parents (Huang et al. 2019). In the present study, we aim to characterize such elite lines derived from MABC and explore their utilization in high oleic peanut germplasm.

Materials and methods

Plant materials

Thirty-four high oleic peanut breeding lines developed by MABC, were selected to identify bacterial wilt resistance in a disease nursery (Table 1). Their recurrent parent Yuanza9102, is a Spanish-type peanut variety with bacterial wilt disease resistance released by the Institute of Industrial Crops, Henan Academy of Agricultural Sciences in 2001. A high oleic germplasm DF12, was the donor parent for high oleic alleles which were selected by fad2 markers in MABC (Huang et al. 2019).

Phenotyping for bacterial wilt resistance

High oleic breeding lines derived from Yuanza9102 were planted in a randomized complete block design with two replications in a bacterial wilt disease nursery (at Hezhou, Guangxi Province) in autumn 2018 and spring 2019. Twenty seeds of each accession were planted in row of 200 cm long with rows 30 cm apart. The numbers of emerging seedlings were recorded two weeks after sowing. At maturation, the established plants of each accession were counted and survival rates were calculated as an indicator of bacterial wilt resistance. Analysis of Variance (ANOVA) tests for survival rates of thirty-eight varieties were conducted by GenStat software 18th edition (VSN International Ltd.).

DNA extraction and marker genotyping

Genomic DNA was extracted from thin slices of mature seeds using the Plant Genomic DNA Kit (TIANGEN BIOTECH CO., Beijing, China). DNA concentrations were measured using NanoDrop 2000 (Thermo Scientific). The Kompetitive Allele Specific PCR (KASP) reaction mixture entailed 2.5 μL DNA template (10 to 20 ng), 2.43 μL of 2×KASP Master Mix (LGC, Hoddesdon, UK), and 0.07 μL KASP Assay mix. The assay mix contains two allele-specific

forward primers and one reverse primer (Table 2). Five breeding lines derived from Yuanza9102 were genotyped by KASP assay to identify bacterial wilt resistance using \textit{qBWA}12 markers previously developed (Qi et al. 2022). All breeding lines derived from MABC were selected by \textit{fad2} KASP markers previously described (Huang et al. 2019).

Yield and quality traits of eight lines derived from Yuanza9102

Eight breeding lines were included in a preliminary test in the spring of 2021 at Yuanyang, Henan Province and planted in randomized complete block design with two replications. 160 seeds of each breeding line were sowed in plot consisted of four rows 40 cm apart and 600 cm long with plant space of 15 cm. Oleic acid content in the kernels of each breeding line was measured by a DA7250 near infrared analyzer (Perten Instruments, Sweden), as previously described (Huang et al. 2019). Yield traits including hundred-pod weight (HPW), hundred-kernel weight (HKW) and shelling percentage were investigated. One-way Analysis of Variance (ANOVA) tests for yield data of eight breeding lines were conducted by GenStat software 18th edition (VSN International Ltd.).

Phylogenetic analysis of five Yuanza9102 derived lines

Eleven accessions including five Yuanza9102 derived lines were genotyped by 40 K SNP panel developed from genotyping by target sequencing (GBTS). A phylogenetic tree was constructed by

Multi-location test

Among the high oleic lines derived from Yuanza9102, HAAS2BC4-140(N)-11–2–3, also known as Yuhua183, was included in the yield test in Jiangxi Province with Changhua1 (CH1) as the check cultivar. Eight accessions were planted in a randomized complete block design with three replications at five locations in 2021. Each plot was 5 m long and 2 m wide. 300 seeds of each accession were sowed per plot. Ten plants from each plot were collected for phenotyping. Maturity date was recorded for each accession. Yield traits were estimated by HPW, HKW and shelling percentage. The whole plots were harvested for yield evaluation. Analysis of Variance (ANOVA) tests for yield data of eight varieties were conducted by GenStat software 18th edition (VSN International Ltd.).

Results

Bacterial wilt resistance of Yuanza9102 derived lines

In spring 2018 and autumn 2019, 34 breeding lines derived from marker assisted backcrossing were tested in the bacterial wilt disease nursery at Hezhou, Guangxi Province (Table 1). Survival rates of the breeding lines were not different from those of recurrent parent Yuanza9102 and resistant check Zhonghua6. These derived lines were distinct from susceptible check Zhonghua12 and high oleic donor parent DF12 based on survival rates (Supplementary Table S1). However, significant variation of survival rates was observed between the years of 2018 and 2019 (Supplementary Table S2).

Variation of yield and quality traits

Eight superior lines derived from Yuanza9102 were investigated for yield related traits in a preliminary test at Yuanyang, Henan province in 2021 (Table 1). The shelling percentage of these lines were not significantly different from one another (Table 3; Supplementary Table S3). Significant variations of HPW and HKW were observed among eight breeding lines.

Tukey’s test was declared for significance at p value threshold of 0.05
The HPW of HAAS2BC4-140(N)-11–2–3 was significantly larger than that of Yuanza9102. The HKW of two breeding lines were significantly lower than that of their recurrent parent, while the HKW of other six lines were similar to Yuanza9102. The oleic acid content of eight Yuanza9102 derived lines was between 72.52 and 75.23%, significantly higher than that of Yuanza9102.

Genetic characterization of Yuanza9102 derived lines

Five superior lines derived from Yuanza9102 were selected and genotyped by 40 K SNP panel (Table 1). Three lines derived from Yuhua15 were also included. The 40 K SNP data of eleven accessions was filtered by minor allele frequency (MAF) of 0.01, resulting in 11,435 SNPs. Phylogenetic analysis showed that these breeding lines were clearly grouped in association with their respective recurrent parent. HAAS2BC4-140(N)-4–10–3 and Yuanza9102 formed a single clade, indicating their close genetic association with each other, distinct from other Yuanza9102 derived lines. HAAS2BC4-140(N)-11–2–3 and HAAS2BC4-118(N)-2–1–1 were both found on separate branches distinct from Yuanza9102, with HAAS2BC4-140(N)-11–2–3 clustered more closely with Yuanza9102 (Fig. 1).

The five lines derived from Yuanza9102 were examined by SNP markers closely linked to bacterial wilt resistance. Their genotypes were the same as the genotype of bacterial wilt resistant parent Yuanza9102 based on KASP results at five SNP loci (Table 4). The five SNPs of high oleic donor parent DF12 were different from those of bacterial wilt resistant accessions, indicating that alleles from...
recurrent parent Yuanza9102 contributed to bacterial wilt resistance in these derived lines.

Yield related traits of Yuhua183 in multi-location test

Yuhua183, namely the breeding line HAAS2BC4-140(N)-11–2–3, matured 4 days earlier than the check cultivar CH1 in the multi-location test in Jiangxi province in 2021 (Table 5). The average shelling percentage of Yuhua183 reached 71.35%, which was the highest among eight varieties (Supplementary Tables S4 and S5). The pod yield and kernel yield (kg/ha) of Yuhua183 were not significantly different from those of the check cultivar at five locations.

Discussion

A spontaneous peanut mutant F435 with elevated oleic acid content was discovered in the U.S. breeding program (Norden et al. 1987). Since then, F435 and its derived lines had been used as the high oleic donor lines in the U.S., leading to the release of several high oleic peanut varieties including ‘SunOleic 95R’, ‘Tamrun OL01’, ‘Tamrun OL02’, ‘Tamrun OL12’ and ‘Florida-07’ (Burow et al. 2014; Gorbet and Knauf 1997; Gorbet and Tillman 2009; Simpson et al. 2003, 2006). The early-maturing variety “Tamrun OL12”, was derived from a single cross between a high oleic runner-type breeding line and an early maturing Spanish-type landrace. In more recent breeding schemes for high oleic peanuts, high oleic trait was pyramided with disease resistance or high oil content by marker assisted selection and marker assisted backcrossing (Chu et al. 2011; Janila et al. 2016; Holbrook et al. 2017; Huang et al. 2019).

Runner-type high oleic peanut accessions released in the U.S. are usually with long growth duration and spreading growth habit. The two-crop rotation cultivation in China is not suitable for planting runner-type peanuts. Cultivars released in China required shorter growth duration and are usually with erect or bunch growth habit. The goal of peanut breeding in China is high yield with growth duration around 120 days adapted to the two-crop rotation system. When the U.S. high oleic peanut germplasm were crossed with Chinese peanut cultivars, the progenies would show wide segregation of yield related traits.

such as growth habit, growth duration, and seed size. Based on a survey of nine released high oleic varieties in the first decades (from year of 2007 to 2017) since introduction of high oleic peanut germplasm, the growth duration of five varieties were longer than 125 days, while the HKW of six varieties were less than 80 g (Wang et al. 2021). Moreover, it is imperative to pyramid disease resistance with high oleic trait to adapt to field conditions with disease and pests. Marker assisted backcrossing is an effective approach to increase oleic acid content in locally adapted cultivars. In the backcross breeding program, our goal is to increase oleic acid content of popular peanut varieties in China. The recurrent parents are usually with erect branching habit and matured earlier than the high oleic donor parents.

To develop high oleic peanut varieties with bacterial wilt resistance, Yuanza9102 was chosen as the recurrent parent in our marker assisted backcross breeding project. Among the advanced lines derived from Yuanza9102, Yuhua183 was selected due to its high oleic acid content and early maturity. Yuhua183 and its recurrent parent Yuanza9102 share competitive characteristics including high shelling percentage. In the multi-location test, the pod yield and kernel yield of Yuhua183 were not significantly different from those of the check cultivar. Genotyping results of 40 K SNP panel and bacterial wilt diagnostic KASP markers indicated that Yuhua183 is a high oleic peanut accession genetically similar to Yuanza9102 and is identified as resistant to bacterial wilt disease.

Conclusion

An elite high oleic peanut cultivar, Yuhua183, was developed by FAD2 marker assisted backcrossing using popular cultivar Yuanza9102 as recurrent parent. The bacterial wilt resistance was evaluated in disease nursery for two seasons, which was validated by qBWA12 diagnostic SNP markers. Phenotypic data at five locations indicated that Yuhua183 matures early with stable yield and high shelling percentage. Yuhua183 is an elite peanut cultivar which expands the genetic background of high oleic peanuts, and is a valuable germplasm resource for further utilization in peanut breeding.

Author contributions XZ and BH were responsible for the research design and supervising. YF drafted the manuscript and analyzed the data. Field work were conducted by HL, QC, HL, FQ, ZZ, BH, LW, WD. Lab work was conducted by XW, MT, FQ, DL, ZS. All authors approved the final manuscript.
