Abstract

Plants, since ancient times, have been used globally across the civilizations as valuable, safe and natural agents of therapeutic, industrial and environmental utilities. From the inception of civilization, humans have relied on plants for their basic necessities like food, shelter, clothing, fuel and health. All the uses ascribed to the plants, the curative abilities of plants play an inevitable part as plants sometimes comprise sole source for healing ailments for some civilizations. Plants have also been explored for population control (*Annona squamosa*) is reported to possess various medicinal effects like insecticidal, anti-viral and abortifacient. The present study therefore reports the effect of ethanolic effect of leaves, bark and seeds on the fructose level in testes, vas deferens and seminal vesicles, sperm count and sperm motility in rats. A significant decrease (p<0.05) was observed in the level of fructose in testis, vas deferens and seminal vesicle on exposure to the ethanolic extract of leaves, bark and seeds of plant (*Annona squamosa*) and a significant (p<0.05) decrease in sperm count and motility was also observed in the rats exposed to the extracts of plant in comparison to control rats. The decrease in fructose level, sperm count and motility was found to be time and dose dependent. Among the different parts of the plant, leaves, bark and seeds the effects were in the order leaf < bark < seed. The study clearly indicates plant extracts have potential to inhibit male fertility.

Abbreviations: (*Annona squamosa*): Sperm Count; Sperm motility; Fructose level; Testis; Vas deferens; Seminal vesicles

Introduction

For centuries, since the arousal of civilization medicinal plants have been used as valuable medicines to cure various ailments of both human and animals. Our ancient literature of Ayurvedic, Siddha, Unani and Chinese medicine provides us a lot of information about the usage of plants to fight diseases. Eighty percent population in the developing countries relies on traditional medicines that use plants for their primary health care. De Lázlo and Hanshaw initiated the interest of the use of plants to induce infertility by describing plant material used by primitive people to affect fertility [1]. Kirtikar and Basu in 1918 and in 1933 compiled the work done on the Indian medicinal plants. Indian Council of Medical Research, New Delhi in the year 1976 and 1987 published two volumes on medicinal plants [2-4].

The most important concern in India is over population that needs to be addressed and tackled. The solution to this problem is population control. Various methods are being used to control the increase in population. There are a number of methods available that are in use for female contraception while for male contraception only the barrier method and vasectomy are available. Thus, there is a need to develop multiple male contraceptive methods. The risk in the usage of the drugs has triggered the need to develop newer products from medicinal plants. The World Health Organization has set up a task force on plant research for fertility regulation with an objective to find new orally active non-steroidal contraceptive. Since then, several commonly used plants have been reported to adversely affect male reproductive functions in wildlife and humans. Local surveys of medicinal plants in our region lead us to exploration of pharmacological properties of plant (*Annona squamosa*).

(*Annona squamosa*) L. Annonaceae also known as custard apple, is a new world fruit tree that has been naturalized throughout the tropics [5]. It is native of tropical America and West Indies, growing up to 3 to 8 meters tall. The leaves are thin, oblong while the flowers are greenish yellow. The ovoid or conical fruit with a purple knobby skin is very sweet and is eaten fresh or can be used for shakes. The fruit is juicy and creamy white, it may contain up to 40 black seeds. It comprises about 120 genera and more than 2000 species [6]. The phyto-chemistry of the Annonaceae has been reviewed by Leboeuf et al. [7]. The moisture content of *A. squamosa* fruit was reported more than 70%. The approximate nutritional composition of (*A. squamosa*) reported was: total carbohydrate 86.5%, protein 7.05%, lipid 0.99%, ash 2.28% and fiber 10.81% respectively. The carbohydrates 10.56 g, glucose 4.32 g, protein 0.22 g, lipids 1.05 g, fiber 0.09 g, citrate 3.53 g respectively were reported.
in (*A. squamosa*) fruit juices. The pH of the fruit juices was acidic and the epicarp, mesocarp, and juice of fruits contained potassium, sodium, iron, magnesium, calcium, chloride and bicarbonate. Carbonate was only present in the fruit juices. The juices also contained phosphorous, zinc and copper.

This plant has recently come under intense scrutiny as potential source of the potent biologically active annonaceous acetogenins isolated from the seed and the bark [8]. Analysis of (*A. squamosa*) seed also reveals the presence of alkaloids [9], terpenoids [10] and saponins [11]. The leaf contains volatile oils. This plant is reported to possess a lot of pharmacological and biological activities due to the presence of these bioactive agents. Hence this paper attempts to explore the effect of ethanolic extract of leaves, bark and seeds of this plant on the fertility of male rats.

Material and Methods

*Annona squamosa* was collected from the areas around the Department of Zoology, D.D.U. Gorakhpur University Gorakhpur and Uttar Pradesh, India. Seeds of (*Annona squamosa*) were collected from fruits while bark and leaves were collected from tree and dried under shade, pulverized by a mechanical grinder and passed through a 50 mesh and stored in airtight containers. The powdered seeds bark and leaves (50g) were extracted with ethanol for 48 hours. This ethanolic extract was dried at controlled temperature (40-50°C) to yield solid powder that was further used for experiments. Healthy colony bred male albino rat weighting 120-150 grams were used for the experiments. The animals were housed in polypropylene cages and these cages were cleaned regularly to avoid rat smell and to maintain standard hygienic conditions (12h light / 12h dark cycles and 25°C ± 5°C at room temperature).

The rats were acclimatized to laboratory conditions for 10 days and fed with standard diet and water was provided ad libitum. The protocol for these experiments was approved by the Departmental Ethical Committee of D.D.U. Gorakhpur University, Gorakhpur, Uttar Pradesh, India, 273009. The animals were divided into three groups, containing 16 animals in each group. A group of rats was administered 200mg/kg body weight /rat/day of the ethanolic extract of seed, bark and leaves of (*Annona squamosa*) and another group was administered 300mg/kg bodyweight/rat/day every morning for 28 days. The remaining third group was fed with vehicle of similar dilution without test material and kept as control group. After every 7th, 14th, 21st and 28th days both control and treated groups four animals from each group were autopsied under light chloroform anesthesia.

Estimation of fructose

Fructose was determined by colorimetric method using resorcinol [12,13].

Sperm count and sperm motility

After anaesthetizing the rats, the caudal epididymis was then dissected. An incision (about 1 mm) was made in the caudal epididymis and drops of sperm fluid were squeezed onto the microscope slide and 2 drops of normal saline were added to mobilize the sperm cells. Epididymal sperm motility was then assessed by calculating motile spermatozoa per unit area. Morphology (abnormality) was evaluated on sperm from the caudal epididymis. The total morphological abnormalities were observed as described by Linde et al. [14]. The left and the right cauda epididymis were incised and the sperm were allowed to swim for 15 min. Solution of 1: 10 dilution is made by adding 90 ml of water to 10 ml of sperm suspension. Sperm counts were done by using haemocytometer.

Calculations of sperm count and sperm motility

\[\text{Sperm count} = (\text{dilution}) \times (\text{count in 5 squares}) \times 0.05 \times 10^6\]

\[\text{Sperm motility} = (\text{Motile sperm}) / (\text{Total sperm}) \times 100\]

Total sperm= Motile sperm + Non-motile sperm

Result and Discussion

A significant decrease (p<0.05) was observed in the level of fructose in testis (Table 1) vas deferens (Table 2) and seminal vesicle (Table 3) on exposure to the ethanolic extract of leaves, bark and seeds of plant (*Annona squamosa*). Two-way ANOVA test indicates that variation in the strength of dose and exposure time significantly influenced the level of fructose in the organs studied. Among the different parts of the plant, leaves, bark and seeds the effects were in the order leaf < bark< seed. This was probably due to the presence of greater number active compounds responsible for the effects or more concentration of the compounds in seed than in bark or leaf. A significant (p<0.05) decrease in sperm count and motility (Table 4) was observed in the rats exposed to the extracts of plant in comparison to control rats. Two-way ANOVA test indicates that variation in the strength of dose and exposure time, significantly (p<0.01) influence the sperm count and motility of male rats on exposure to the extracts (Table 4).

Fructose is formed almost entirely in the seminal vesicles and is the most important energy source for sperm [15]. The determination of fructose concentration of seminal vesicle provides clues to secretory function of seminal vesicle which are under testosterone control [16]. The seminal fructose has been suggested to arise from glucose via glucogen phosphohexose pathway in the presence of phosphohexoisomerase and alkaline phosphatase. The process of fructose formation in seminal vesicles is initiated and controlled by the testicular androgens [17,18]. A decrease in the fructose level on exposure to leaf, bark and seed extract of the plant affects sperm motility and viability since fructose serves as energy source for the sperm. Fructose is androgen dependent and its decrease indicates reduction in the circulating androgens. Absence of fructose is an indication of obstruction either in vas deferens or the epididymis [19-21].

It is reported by Ahmad et al [22] that percentage of abnormal sperms increases with decrease in the fructose level in epididymis, seminal vesicles and vas deferens. This was evident in the present study also. Depletion of sperm count and sperm motility in the extract treated rats suggests alteration in sperm production in the testes and maturation in the epididymis. The reduction in sperm count and motility in cauda epididymis is important with regard to fertilization [23,24]. Decrease in sperm motility is associated with an increase in the percentage of dead and morphologically abnormal spermatozoa. The decrease in the caudal Epididymal sperm counts when compared to control rats indicates that, the
 extracts of leaves, bark and seeds of *Annona squamosa* can affect one or more aspects of spermatogenesis. It affects the hormonal mechanisms concerned with the regulation of spermatogenesis. The decreased sperm motility observed in the study may be an effect of altered function of the accessory organs [25]. Mishra and Singh [26] also reported decreased sperm count in male albino rats after treatment with aqueous leaf extract of (*Azadirachta indica*). During the present study depletion of sperm count observed in animals after exposure to plant extracts and decreased number of sperms suggests alteration in the sperm production in testes probably due to disturbances in the process of spermatogenesis as observed by various other researchers while working with different plant products. Changes in both sperm count and motility results in partial infertility within twenty eight days. An abnormal sperm function ultimately gives rise to male sterility. Moreover, in our study, a low fructose concentration with different doses of plant extracts could be another cause of reduction in sperm motility since motile sperm consumes fructose after ejaculation [27-29].

Among the plant based contraceptives, inhibition of male fertility after administration of natural substances has been related to decreased spermatozoa density [30]. For male contraception, it is not necessary to stop spermatogenesis, but it is enough to eliminate the fertilizing ability of the spermatozoa by causing changes in the morphology or in the function of sperm [31].
