LONG-TERM treatment with inhaled corticosteroids has been shown to result in improvement of symptoms and lung function in subjects with asthma. Arachidonic acid (AA) metabolites are thought to play a role in the pathophysiology of asthma. It was assessed whether differences could be found in bronchoalveolar lavage (BAL) AA metabolite levels between subjects with asthma who were treated for 2.5 years with inhaled bronchodilators alone or in combination with inhaled corticosteroids. Prostaglandin (PG)\textsubscript{D2}, PGF\textsubscript{2\alpha}, 6-keto-PGF\textsubscript{1\alpha}, thromboxane B\textsubscript{2}, leukotriene (LT)\textsubscript{C4} and LTB\textsubscript{4} levels and cell numbers were assessed in BAL fluid from 22 non-smoking asthmatic subjects. They were participating in a randomized, double-blind multicentre drug trial over a period of 2.5 years. Results of the group treated with inhaled corticosteroids (CS\textsuperscript{+}: beclomethasone 200 μg four times daily) were compared with the other group (CS\textsuperscript{-}) which was treated with either ipratropium bromide (40 μg four times daily) or placebo. BAL LTC\textsubscript{4} levels of asthmatic subjects were significantly lower after 2.5 years inhaled corticosteroid therapy (CS\textsuperscript{+}, 9(1-17) pg/ml vs. CS\textsuperscript{-}, 16(6-53) pg/ml; \(p<0.01\)). The same trend was observed for the PGD\textsubscript{2} levels. The results suggest that inhaled corticosteroids may exert their beneficial effect on lung function via a mechanism in which inhibition of LTC\textsubscript{4} synthesis in the airways is involved.

Key words: Arachidonic acid metabolites, Asthma, Bronchoalveolar lavage, Corticosteroids, Leukotriene C\textsubscript{4}, Prostaglandin D\textsubscript{2}

Introduction

Recent long-term studies on the prognosis and morbidity of obstructive airways disease have shown that addition of inhaled corticosteroids to maintenance treatment with a \(\beta_2\)-agonist in hyper-responsive patients with obstructive airways disease leads to a significant reduction of respiratory symptoms, exacerbation rates, airway obstruction and airway hyper-responsiveness.\textsuperscript{1-2} These findings are thought to be a consequence of suppression of inflammatory processes in the airways.

No single cell type or mediator in the inflammatory processes in the airways is responsible for the clinical events in asthma. Nevertheless, there is now substantial evidence that arachidonic acid (AA) metabolites play an important role in the pathophysiology of the disease. They are potent airway constrictors, increase mucus secretion, play a role in chemotaxis and may enhance airway responsiveness, one of the characteristics of the disease.\textsuperscript{3} A role for AA metabolites in the modulation of severity of asthma is suggested by the presence of higher levels in BAL fluid as compared to those in healthy subjects, increasing even more after allergen provocation.\textsuperscript{4-5}

One potential mode of action of inhaled corticosteroids involves the modulation of arachidonic acid (AA) metabolite levels in the airways.\textsuperscript{6} They may decrease AA metabolite synthesis by their inhibitory effect on phospholipase A\textsubscript{2} or by inhibition of synthesis of cytokines that stimulate AA metabolite release. In order to assess the role of AA metabolites in the effects of long-term treatment of asthmatic subjects with corticosteroids, AA metabolite levels in bronchoalveolar lavage (BAL) fluid were assessed in a subgroup of non-smoking asthmatic patients who participated in a randomized, double-blind multicentre drug trial for 2.5 years.

Lower leukotriene C\textsubscript{4} levels in bronchoalveolar lavage fluid of asthmatic subjects after 2.5 years of inhaled corticosteroid therapy

**Materials and Methods**

**Patient selection:** Before entering the multicentre drug intervention trial, patients were selected based on: (1) Baseline FEV$_1$ larger than 1.21 (ranging between 4.5 and 1.6 residual standard deviations below the predicted value), or an FEV$_1$/inspiratory vital capacity (IVC) ratio lower than 1.64 RSD below the predicted value, provided that total lung capacity was higher than 1.64 RSD below the predicted level; (2) airway hyper-responsiveness to histamine, defined as the provocative concentration of histamine that caused 20% decrease in FEV$_1$ (PC$_{20}$) ≤ 8 mg/ml; and (3) exclusion of pregnant women, patients who used oral corticosteroids, β-blockers, nitrates, or anticoagulants, and patients who continuously used antibiotics.

At enrolment, the subjects were assigned to one of three double-blind regimens using identical metered dose inhalers: all patients received an inhaled β$_2$-agonist (terbutaline 500 µg) combined with either an inhaled corticosteroid (beclomethasone dipropionate 200 µg), an inhaled anticholinergic (ipratropium bromide 40 µg) or an inhaled placebo. All medication was taken four times daily.

**Study design:** AA metabolites and cell numbers were analysed in BAL fluid obtained from outpatients from two university pulmonary departments (Groningen and Rotterdam), 2.5 years after participation in the above-indicated randomized, double-blind multicentre drug intervention trial. At the time of selection of patients for this study and bronchoscopy the patients were still receiving their trial medication. Therefore, the investigators were blind to the treatment that had been received in the preceding 30 months. Analysis was performed only in BAL fluid obtained from 22 non-smoking patients with asthma, diagnosed by criteria from a standardized history of respiratory symptoms and with a reversibility of airways obstruction ≥ 9% of FEV$_1$ % predicted at entry.

In accordance with findings in all participants of the trial, no significant differences in FEV$_1$ values, reversibility of airway obstruction and airway responsiveness to histamine obtained at the last visit preceding the bronchoscopy procedure were found between asthmatic patients assigned to the placebo and anticholinergic groups. Therefore, differences in BAL parameters in this study were investigated between the groups without (i.e. placebo + anticholinergic therapy) and with inhaled corticosteroid therapy.

Correlations between BAL data and lung function parameters obtained 1 week preceding the bronchoscopy procedure were investigated. The study protocol was approved by the medical ethics committees of the participating hospitals. All patients gave written informed consent.

**Pulmonary function and inhalation provocation tests:** FEV$_1$ was performed on water-sealed spirometers according to standardized guidelines, before and 20 min after four single inhalations of 250 µg of terbutaline administered through a 750-ml spacer device (Nebuhaler). Histamine provocation tests were performed using a 2 min tidal breathing method, as described previously. Measurements were made only during clinical stable periods, and not within 4 weeks after the termination of a course of prednisolone. All pulmonary medications were discontinued 8 h before each test.

**Bronchoalveolar lavage:** Fibre optic bronchoscopy (Olympus B1 TT10, Tokyo, Japan) was undertaken according to the guidelines of the American Thoracic Society. Premedication consisted of intramuscular injection of 0.5 mg atropine and inhalation of 500 µg terbutaline 30 min before the procedure. Lidocaine 4% was administered into the upper airways and bronchial tree. Bronchoalveolar lavage was performed with 1 × 30 ml (pool 1) and 4 × 50 ml (pool 2) sterile phosphate-buffered saline (PBS) at 37°C with the bronchoscope wedged in the lateral segment of the right middle lobe. After recovery by gentle suction (−40 cm H$_2$O), the BAL fluid was collected in a siliconized specimen trap placed on melting ice.

Immediately after collection of the BAL fluid the laboratory procedures were carried out. The BAL fluid was centrifuged at 400 × g at 4°C for 5 min. BAL supernatant was separated from the cell pellet. The cell pellets were washed in PBS supplemented with 0.5% heat-inactivated bovine serum albumin (BSA). Total leukocyte numbers in BAL cell suspensions were counted in a Coulter Counter and viability was assessed by cellular exclusion of trypan blue. Cell differentials were done on May–Grunwald–Giemsa stained cytocentrifuge preparations. At least 500 cells were counted.

**AA metabolite determination:** Immediately after the BAL procedure, 20 ml of BAL supernatant from pool 2 was processed on C18 SepPak cartridges (Millipore, Bedford, USA) as described previously, eluted with 2.5 ml methanol and stored at −80°C until analysis. Samples of 200 µl BAL eluted fluid were pipetted into polypropylene tubes and dried with a Savant sample con-

Results

Subjects: Patient characteristics and lung function parameters at entry in the study in the groups with (CS+, n = 9) and without (CS−, n = 13) corticosteroid treatment are listed in Table 1. Comparing group data at entry in the trial retrospectively, no significant differences in patient characteristics and lung function parameters were found between the groups. In contrast, after 2.5 years of double-blind, randomized treatment, a significant improvement in FEV1, reduction in reversibility of airway obstruction and reduction in airway responsiveness to PC_{20} histamine were found in the CS+ as compared to the CS− group (Table 2).

BAL cell numbers and levels of AA metabolites:
The percentage recovery of BAL fluid was significantly higher in the CS+ than in the CS− group (p = 0.01). There were no significant differences in median total or differential cell numbers/ml BAL fluid between the groups (Table 3). The median LTC4 level in the CS+ group was significantly lower than the level in the CS− group (p = 0.01), while the median PGD2 level showed the same trend (Table 4). The levels of other investigated AA metabolites were not significantly different between the CS+ and CS− groups.
**Table 3.** Effect of inhaled corticosteroids on BAL fluid volume and cell numbers (pool 2)

| Parameter          | CS^-  | CS^+  | \( p \) |
|--------------------|-------|-------|---------|
| Recovery %         | 56 (10-68) | 63 (33-72) | 0.01    |
| Total leukocytes \( \times 10^3/\text{ml} \) | 86 (14-212) | 123 (26-431) | N.S.    |
| Alveolar macrophages | 79 (9-180) | 98 (21-348) | N.S.    |
| Lymphocytes        | 3 (0-16) | 7 (0-72) | N.S.    |
| Neutrophils         | 1 (0-19) | 2 (0-7) | N.S.    |
| Eosinophils         | 1 (0-9) | 2 (0-4) | N.S.    |

Medians with range. CS^- and CS^+ = asthma groups treated without and with inhaled corticosteroids, respectively.

**Table 4.** BAL AA metabolite levels (pg/ml)

| Metabolite | CS^-  | CS^+  | \( p \) |
|------------|-------|-------|---------|
| PGD_2      | 77 (16-200) | 28 (17-138) | 0.12    |
| PGE_2      | 19 (6-26) | 15 (5-36) | N.S.    |
| TXB_2      | 16 (8-30) | 13 (7-24) | N.S.    |
| LTC_4      | 16 (6-53) | 9 (1-17) | 0.01    |
| LTD_4      | 75 (15-138) | 96 (23-279) | N.S.    |

Medians with range. CS^- and CS^+ = asthma groups treated without and with inhaled corticosteroids, respectively.

**Correlation with lung function:** LTC_4 levels correlated significantly with FEV_1 % pred. (\( \rho = -0.46, p = 0.03 \)) (Fig. 1). PGD_2 levels correlated significantly with FEV_1 % pred. (\( \rho = -0.62, p = 0.002 \)), as did PC_{20} histamine (\( \rho = -0.50, p = 0.02 \)) and the reversibility of airways obstruction (\( \rho = -0.52, p = 0.01 \)).

**Discussion**

This study started from the hypothesis that suppression of inflammatory processes in the airways underlies the improvement in lung function observed after long-term treatment with inhaled corticosteroids. AA metabolite levels are considered as biochemical markers of on-going chronic airway inflammation in the airways of asthmatic subjects. Therefore, we investigated whether differences in BAL AA metabolite levels could be detected between subjects treated with \( \beta_2 \)-agonists and inhaled corticosteroids for 2.5 years and those treated with inhaled \( \beta_2 \)-agonists alone. Results from this study show that the BAL LTC_4 levels are significantly lower in asthmatic patients treated with inhaled corticosteroids. The same trend is observed for PGD_2 levels. The median BAL AA metabolite values of the corticosteroid treated group were within the same level as those from a control group of eight non-smoking, non-atopic healthy subjects who were concurrently analysed during the same procedure.

This is the first study in which AA metabolite levels were measured after long-term treatment with inhaled corticosteroids. In contrast to our results, short-term treatment with prednisolone 60 mg/day has been reported to have no significant effect on BAL fluid AA metabolite levels in asthmatic subjects, although the *in vitro* synthesis of AA metabolites by BAL cells was decreased. A lower production of LTC_4 by BAL cells was also found in asthmatic subjects who had been treated for more than 2 years with 5-15 mg prednisone, which is in line with our results. A role for cysteinyl leukotrienes in the pathophysiology of asthma is suggested by findings that leukotrienes induce airway obstruction,
increase airway hyper-responsiveness and increase mucous secretion. After oral treatment with a leukotriene D<sub>4</sub> receptor antagonist a significant reduction in asthma symptoms and improvement of lung function has been reported in asthmatic subjects. In the light of current knowledge, several mechanisms can be postulated to explain the reduced LTC<sub>4</sub> levels in the CS-treated group. First, corticosteroids exert a decreased cellular AA metabolism synthesis by inhibiting phospholipase A<sub>2</sub> activation through the generation of lipocortin. Results from this study suggest that cells that predominantly release LTC<sub>4</sub> (eosinophils, alveolar macrophages, mast cells) are more sensitive to corticosteroid treatment. Secondly, corticosteroids may selectively inhibit the transcription of cytokines from airway cells that may regulate LTC<sub>4</sub> release. IL-3, IL-5 and GM-CSF have been shown to prime human basophils, eosinophils and neutrophils for augmented release of LTC<sub>4</sub> after stimulation by a second agonist.

Results of this study suggest an effect of long-term corticosteroid treatment on BAL PGD<sub>2</sub> levels as well. PGD<sub>2</sub> is a potent airway constrictor and is implicated in the increase in airway responsiveness. PGD<sub>2</sub> is synthesized by a variety of airway cells. It has been observed that the in vitro PGD<sub>2</sub> synthesis by human lung mast cells was not affected by glucocorticoids. The PGD<sub>2</sub> synthesis by human alveolar macrophages upon stimulation by calcium ionophore A23187 was, however, significantly inhibited by methyl prednisolone. If in vitro results can be extrapolated to the in vivo situation, the results favour a role for PGD<sub>2</sub> release by alveolar macrophages in the chronic inflammatory process in asthma.

We did not find a difference in total or differential cell numbers between the groups. Previous findings in studies on the effect of short-term corticosteroid treatment (6 weeks to 4 months) on BAL cell numbers are not consistent, although in the majority a reduction of BAL eosinophil numbers was found. It cannot be excluded that we did not find differences as a consequence of group sizes that were too small. Inflammatory processes in the airways are, however, probably better reflected by cell activation than increased cell numbers in the BAL fluid, as has been found in this study.

In conclusion, this study shows that BAL LTC<sub>4</sub> levels of asthmatic subjects were significantly lower after 2.5 years inhaled corticosteroid therapy. The results suggest that corticosteroids may exert their beneficial effect on lung function via a mechanism in which inhibition of LTC<sub>4</sub> synthesis in the airways is involved.
