(Dated: October 22, 2020)

The static and dynamic electric-dipole polarizabilities and tune-out wavelengths for the ground state of Cs atoms are calculated by using a semiempirical relativistic configuration interaction plus core polarization approach. By considering the hyperfine splittings, the static and dynamic polarizabilities, hyperfine Stark shifts, and tune-out wavelengths of the hyperfine components of the ground level of $^{133}$Cs atoms are determined. It is found that the hyperfine shifts of the first primary tune-out wavelengths are about $-0.0135$ nm and $0.0106$ nm, which are very close to the hyperfine interaction energies. Additionally, the contribution of the tensor polarizability to the tune-out wavelengths is determined to be about $10^{-5} - 10^{-6}$ nm.

I. INTRODUCTION

With the rapid development of laser cooling and trapping technologies, high-precision measurements of atomic spectra were remarkably developed in the past two decades. In an optical lattice, atoms could be trapped by a dipole force proportional to the dynamic polarizability $\beta$. At certain laser wavelengths, however, the dynamic polarizability becomes null and, accordingly, the dipole force between atoms and laser field vanishes as well. These laser wavelengths are termed as “tune-out wavelengths” by LeBlanc and Thywissen [2]. The tune-out wavelengths are very useful for sympathetic cooling in two-species mixtures of alkali-metal atoms such as Li-Cs [2, 4], K-Rb [2, 5], Rb-Cs [2], K-Cs [2] and $^{39}$K-$^{40}$K [2] mixtures.

High-precision measurements of tune-out wavelengths can be used to determine atomic parameters such as the ratios of line strengths or oscillator strengths [6–8]. For example, the longest tune-out wavelength of the ground state of K was measured with an uncertainty of 1.5 pm [9], and the ratio of the $4s \to 4p_j$ line strengths was obtained with an accuracy of 0.0005. The longest tune-out wavelength of the $5s_{1/2}, F = 2$ state of $^{87}$Rb was measured with an accuracy of about 30 fm [10, 11], and the ratio of the $5s_{1/2} - 5p_j$ line strengths was determined with an accuracy of 0.007. The longest tune-out wavelength of the metastable state of He has been measured with an uncertainty of 1.8 pm [12]. This tune-out wavelength has been recommended to test the quantum electrodynamics (QED) effect [12, 13]. Additionally, a tune-out wavelength of $^7$Li was measured with an uncertainty of 2.2 fm [14].

Cs atoms are used in a wide range of applications including atomic clocks, quantum information, and quantum communication [15–17]. These applications require an accurate understanding of atomic properties of Cs atoms, in particular, electric-dipole (E1) matrix elements and polarizabilities. In order to obtain highly accurate E1 transition matrix elements of Cs atoms, high-precision measurements and calculations of its tune-out wavelengths are required. Arora et al. [15] calculated the tune-out wavelengths of the $6s_{1/2}$ state of Cs atoms by using a relativistic all-order method. However, the effect of the hyperfine interactions on the tune-out wavelength was not considered. In order to obtain high-precision tune-out wavelengths, the contribution of the hyperfine interactions should be taken into account. To the best of our knowledge, the tune-out wavelengths of Cs atoms are not experimentally measured yet.

In this paper, the static and dynamic polarizabilities as well as three tune-out wavelengths are calculated by using a semi-empirical method—the so-called relativistic configuration interaction plus core polarization (RCICP) method, which was developed based on a nonrelativistic configuration interaction method plus a core polarization model [19]. By considering the hyperfine splittings, the E1 matrix elements between the hyperfine states, the static and dynamic polarizabilities and the tune-out wavelengths of the hyperfine components of the ground level of $^{133}$Cs atoms are determined. Atomic units are used throughout the text unless specified otherwise.

II. THEORY AND CALCULATIONS FOR THE $6s_{1/2}$ GROUND STATE OF CS ATOMS

A. Energies of low-lying states

The basic strategy of the theoretical model used is to partition a Cs atom into a core Cs$^+$ plus a valence electron. The first step involves a Dirac-Fock (DF) calculation of the core. The orbitals of the core are expressed as linear combinations of $S$-spinors, which can be treated as a relativistic generalization of the Slater-type orbitals [20–23]. The Hamiltonian of the valence electron is written as

$$H = c\alpha \cdot \mathbf{p} + (\beta - 1)c^2 + V_{\text{core}}(\mathbf{r}),$$

(1)
TABLE I. Cutoff parameters $\rho_{\ell,j}$ of the polarization potential of the Cs$^+$ core.

| $\ell$ | $j$ | $\rho_{\ell,j}$ (a.u.) |
|--------|----|-------------------|
| $s$    | $1/2$ | 2.78449          |
| $p$    | $1/2$ | 2.66646          |
| $d$    | $3/2$ | 2.68025          |
|        | $5/2$ | 3.19976          |

where $\alpha$ and $\beta$ are $4 \times 4$ matrices of the Dirac operator, $p$ is the momentum operator, and $c$ is the speed of light, $r$ is the position vector of the valence electron. The effective interaction potential $V_{\text{core}}(r)$ can be expressed as

$$V_{\text{core}}(r) = -\frac{Z}{r} + V_{\text{dir}}(r) + V_{\text{exc}}(r) + V_p(r).$$

Here, $Z$ is atomic number, $r$ is the distance of the valence electron with respect to the origin of the coordinates, the direct and exchange interactions $V_{\text{dir}}$ and $V_{\text{exc}}$ of the valence electron with the DF core are calculated exactly, while the $\ell$-dependent polarization potential $V_p$ is treated semiamperically as follows,

$$V_p(r) = -\sum_{k=1}^{2} \frac{\alpha_{\ell,j}^{(k)}}{2\pi^{\ell/2}} \sum_{\ell,j} g_{\ell,j}^2(r) |\ell\rangle \langle \ell|.$$

Here, $\ell$ is the orbital angular momentum quantum number, $j$ is the total angular momentum quantum number, the factor $\alpha_{\ell,j}^{(k)}$ is the $k$th-order static polarizability of the core with $\alpha_{\ell,j}^{(1)} = 15.8(1)$ a.u. [24] for dipole polarizability and $\alpha_{\ell,j}^{(2)} = 86.4$ a.u. [25] for quadrupole polarizability. $g_{\ell,j}^2(r) = 1 - \exp(-r^6/\rho_{\ell,j})$ is a cutoff function designed to make the polarization potential finite at the origin. The cutoff parameters $\rho_{\ell,j}$, as listed in Table [I], are tuned to reproduce the binding energies of the ground state and some low-lying excited states.

The corresponding effective Hamiltonian is diagonalized in a large $L$-spinor basis. [20, 24]. $L$-spinors can be regarded as a relativistic generalization of the Laguerre-type orbitals that are often utilized in solving the Schrödinger equation [27]. The present calculations used 50 positive energy and 50 negative energy $L$-spinors for each $(\ell, j)$ symmetry. In Table [II] we list the presently calculated energy levels for some low-lying states of Cs atoms, together with other experimental results from the National Institute of Standards and Technology (NIST) tabulation [28]. Good agreement is obtained.

B. Dipole transition matrix elements

The E1 transition matrix element can be expressed as

$$T_{ij} = |\langle \gamma_i J_i | \mathbf{D} | \gamma_j J_j \rangle|,$$

where $\gamma$ represents all additional quantum numbers in addition to the total angular momentum $J$. $\mathbf{D}$ is the dipole transition operator. In the present calculations, $T_{ij}$ is computed with the use of a modified transition operator $57, 61$

$$D = r - [1 - \exp(-r^6/\rho^6)]^{1/2} \frac{\alpha_{\ell,j}^{(1)}}{\rho^3},$$

where the cutoff parameter $\rho = 3.6280$ a.u. is chosen to ensure that the presently calculated static polarizability equals the measured value 400.84(4) a.u. [62].

In Table [III] we list the presently calculated reduced matrix elements for a number of principal E1 transitions of Cs atoms, which are compared with the all-order single, double, and triple excitations scaled valence (SDpTsc) [24] as well as other theoretical and experimental results. The column labeled by $Z_{\text{final}}$ shows the final results of Ref. [24] calculated with inclusion of higher-order correlation. For the $6s1/2 \to 6p1/2,3/2$ transitions, the present results differ from the results of $Z_{\text{final}}$ by about 0.8%. Overall, the present RCICP results are in excellent agreement with the experimental results from Young et al. [49] and Patterson et al. [37]. As for the $6s1/2 \to 7p_{1/2,3/2}$ transitions, the present results are in good agreement with the experimental results in Refs. [38, 40, 42, 43]. Furthermore, the present results for
TABLE III. Comparison of the presently calculated reduced E1 matrix elements (a.u.) and line strength ratios for principal transitions of Cs atoms with other available experimental and theoretical results. The uncertainties are given in parentheses.

| Van der Waals coefficient C6 [54] | 34.82(36) | 4.5051(23) | 30.41(30)  | 6.340(31)   |
| Fast-beam laser [32]          | 35.07(10)  | 4.4890(64) | 30.57(7)   | 6.3236(71)  |
| Ultrafast excitation and ionization [55] | 30.460(38) | 6.3351(39) |
| Ultrafast excitation and ionization [37] | 30.462(46) | 6.3349(41) |
| Fast-beam laser [56]          | 30.55(27)  | 6.3258(81) |

the $7s_{1/2} \rightarrow np_{j}(n = 6, 7, 8)$ transitions agree very well with the results in Refs. [22, 30, 44, 65, 64]. Uncertainties of the present results, as well as those of $Z_{\text{final}}$, are given in Table III in parentheses after the values in units of the last digit of the value. The method of estimation of the uncertainties of our calculations is explained in Section IV.

Besides the E1 reduced matrix elements, the ratio of the line strengths (i.e., squares of the E1 matrix elements) of the $6s_{1/2} \rightarrow 6p_{1/2}$ and $6s_{1/2} \rightarrow 6p_{3/2}$ transitions are also given in Table III. Although this ratio should be exactly 2.0 in the nonrelativistic limit, both the present and other available results indicate that it is slightly smaller than 2.0. The reason for such a deviation from 2.0 is the spin-orbital splitting of Cs atoms. Nevertheless, the present RCICP ratio 1.9844(100) agrees excellently with the experimental value 1.9845(69) [32]. In contrast, the corresponding ratio for the $6s_{1/2} \rightarrow 7p_{1/2,3/2}$ transitions
differs substantially from 2.0, but the present RCICP result is still in good agreement with the experimental results \[38 40 42 43\] and differs from \(Z_{\text{final}}\) of Ref. 29 only by about 6%.

As there is only one spontaneous decay channel \(\delta_{p_{1/2}} \rightarrow 6s_{1/2}\) for each of the \(6p_{j}\) states, experimentally measured lifetimes of the states can be used to determine the transition matrix elements. Table \[V\] lists the presently calculated lifetimes of the \(6p_{1/2}\) and \(6p_{3/2}\) states together with other experimental results \[32, 37, 49, 53–56\]. The present RCICP lifetime of the \(6p_{1/2}\) state is smaller than the experimental result \[32\] by about 0.6%. Nevertheless, it is still in good agreement with other experimental results \[49, 53, 54\]. For the \(6p_{3/2}\) state, the present lifetime agrees well with the experimental results from Refs. \[37, 49, 53–55\], while it is smaller than the experimental results of Tanner et al. \[50\] and of Rafac et al. \[32\] just by about 0.3%.

### C. Polarizabilities of the ground state

The scalar dynamic polarizability of the ground state is written as \[65\]

\[
\alpha^S(\omega) = \sum_n \frac{f_{0-n}}{(\Delta E_{0-n} - \omega^2)}.
\]

where \(\Delta E_{0-n} = E_n - E_0\) is the transition energy, the summation over \(n\) includes all allowable fine-structure transitions, \(\omega\) is the frequency of the external field, \(f_{0-n}\) denotes the oscillator strength of a dipole transition, which is defined as

\[
f_{0-n} = \frac{2|\langle \gamma_n J_n | D_0 | \gamma_0 J_0 \rangle|^2 \Delta E_{0-n}}{3(2J_0 + 1)}.
\]

If \(\omega = 0\), the dynamic polarizability in Eq. (6) is reduced to the static polarizability. By using the experimental energy levels and \(E_1\) matrix elements obtained above, the static dipole polarizability can be readily calculated. In Table \[V\] we list the presently calculated static dipole polarizabilities of the ground state of Cs atoms together with other available results. The present RCICP results agree very well with the theoretical results of \(R\)-\textit{ab-initio} \[67\], RCC-SD \[66\], R-SD \[66\] and R-all-order \[68\] methods.

### D. Tune-out wavelengths

FIG. 1 shows the dynamic polarizabilities of the ground state of Cs atoms. Three visible tune-out wavelengths are found, as indicated by arrows. For the present atomic system, the tune-out wavelengths appear in two cases. In the first case, the tune-out wavelengths lie between the \(6s \rightarrow np_1(n = 6, 7)\) fine-structure components. For example, the tune-out wavelength 880.2510 nm lies between the \(6s_{1/2} \rightarrow 6p_{1/2,3/2}\) resonances, while the one 457.2428 nm lies between the \(6s_{1/2} \rightarrow 7p_{1/2,3/2}\) resonances. In the second case, the tune-out wavelength lies between the \(6s_{1/2} \rightarrow np_3\) and \(6s \rightarrow (n + 1)p_{1/2}(n = 6, 7, \ldots)\) transitions. For example, the tune-out wavelength 460.1897 nm lies between the \(6s_{1/2} \rightarrow 6p_{3/2}\) and \(6s_{1/2} \rightarrow 7p_{1/2}\) transitions. In comparison, the present RCICP tune-out wavelengths are found to be very close to the theoretical results of Arora et al. \[18\], as seen from Table \[VI\].

Besides the tune-out wavelengths, Table \[VI\] also lists the breakdown of the contributions to the dynamic polarizabilities at the tune-out wavelengths. It is found that the 880-nm tune-out wavelength is mainly caused by a cancellation of the contributions from the \(6s_{1/2} \rightarrow 6p_{1/2}\) and \(6s_{1/2} \rightarrow 6p_{3/2}\) transitions; the contributions from other transitions are negligibly small. At the tune-out wavelengths near 460 nm and 457 nm, the main contributions to the dynamic polarizabilities are from the transitions from the \(6p_{1/2}\) and \(7p_{1/2}\) states. These tune-out wavelengths can be effectively determined by means of a relative magnitude of the \(6s_{1/2} \rightarrow 6p_{1/2,3/2}\) and \(6s_{1/2} \rightarrow 7p_{1/2,3/2}\) matrix elements or oscillator strengths.

Since more accurate experimental results 6.3349(48) a.u., 4.5057(16) a.u., 0.27810(54) a.u., and 0.57417(57) a.u. of the \(6s_{1/2} \rightarrow 6p_{1/2,3/2}\) and \(6s_{1/2} \rightarrow 7p_{1/2,3/2}\) transition matrix elements can be obtained from Ref. \[33\] \[38\], we recalculate the tune-out wavelengths by replacing the corresponding RCICP matrix elements with these experimental values, which are labeled as \(\lambda_{\text{zero}}\) in Table \[VI\]. Evidently, the uncertainties of \(\lambda_{\text{zero}}\) are much smaller.

less than those of the RCICP tune-out wavelengths. Therefore, in the calculations of polarizabilities and tune-out wavelengths for the hyperfine components of the ground level in Sec. III, the RCICP matrix elements of the $6s_{1/2} \rightarrow 6p_{1/2,3/2}$ and $6s_{1/2} \rightarrow 7p_{1/2,3/2}$ transitions are replaced by the experimental values. Also, the RCICP calculation results are listed in the Supplemental Materials $[73]$.

![Dynamic polarizabilities of the ground state of Cs atoms. Three visible tune-out wavelengths are found, which are marked with arrows. Approximate positions of the $6s_{1/2} \rightarrow npl$ resonances are indicated by vertical dotted lines.](image)

III. CALCULATIONS FOR THE HYPERFINE COMPONENTS OF THE GROUND LEVEL OF $^{133}$Cs

A. Energies and reduced matrix elements

In order to further consider the effect of the hyperfine interaction on the polarizabilities, the theory of energies and reduced matrix elements should be reformulated. The energy of a hyperfine state is given by

$$E_{\mathbf{hf}} = E_{\mathbf{J}} + W_{\mathbf{F}},$$

where $E_{\mathbf{J}}$ is the energy of an unperturbed fine-structure level. $W_{\mathbf{F}}$ represents the hyperfine interaction energy, which can be expressed as

$$W_{\mathbf{F}} = \frac{1}{2} A R + B \frac{3}{2} R (R + 1) - 2 I (I + 1) J (J + 1),$$

where $A$ and $B$ denote the hyperfine structure constants, $I$ is the nuclear spin ($I = 7/2$ for $^{133}$Cs), and $J$ is total angular momentum of fine-structure energy levels. $R$ is given by

$$R = F (F + 1) - I (I + 1) - J (J + 1)$$

with total angular momentum $F$ of hyperfine-structure energy levels.

In Table VII we list the hyperfine structure constants $A$ and $B$, the hyperfine interaction energies, and the hyperfine energy levels.

By means of the Wigner-Eckart theorem, the transition matrix elements between two hyperfine states $|\gamma_i J_i I F_i\rangle$ and $|\gamma_g J_g I F_g\rangle$ can be written as

$$T_{\gamma i}^{\mathbf{hf}} = \langle \gamma_i J_i I F_i | \mathbf{D} | \gamma_g J_g I F_g \rangle = (-1)^{I + J_g + F_i + 1} \frac{F_i}{F_g} J_i J_g T_{\gamma i}.$$
Here, \( \Delta \) hyperfine absorption oscillator strength \( f \) initial- and final-state binding energies. The uncertainties are given in parentheses.

The calculation of dipole scalar polarizabilities for the hyperfine states is rather similar to Eq. (6), except that \( J_0 \) should be replaced by \( F \) and the matrix element is replaced by Eq. (11). Because the total angular momentum of the hyperfine components of the ground level is greater than one, the corresponding dipole polarizability has a tensor component, which can be written as

\[
\alpha = 6 \left( \frac{5F_g(2F_g-1)(2F_g+1)}{6(F_g+1)(2F_g+3)} \right) ^{1/2} \times \sum_i (-1)^{F_g+i} \begin{pmatrix} F_g & 1 & F_i \\ 1 & F_g & 2 \end{pmatrix} \frac{\Delta E_{g\to i}}{\Delta E_{g\to i}^2 - \omega^2}. \tag{12}
\]

Here, \( \Delta E_{g\to i} = E_i^\text{hf} - E_i \). The total polarizability of a hyperfine state is given as

\[
\alpha_{M_F} (\omega) = \alpha^S (\omega) + \alpha^T (\omega) \frac{3M_F^2 - F_g(F_g+1)}{F_g(2F_g-1)}, \tag{13}
\]

in which \( M_F \) is the magnetic component of the quantum number \( F_g \).

In the calculations of polarizabilities, small corrections to the matrix elements of the \( 6s_{1/2} \rightarrow 6p_{1/2,3/2} \) transitions are made, which are treated as parametric functions of the binding energies of the lower and upper levels and can be written as

\[
T'_{6s_{1/2},6p_j} \approx T_{6s_{1/2},6p_j} + \frac{\partial T_{6s_{1/2},6p_j}}{\partial E_{6s_{1/2}}} W_{F_{6s_{1/2}}} + \frac{\partial T_{6s_{1/2},6p_j}}{\partial E_{6p_j}} W_{F_{6p_j}}, \tag{14}
\]

where \( T_{6s_{1/2},6p_j} \) denotes the \( 6s_{1/2} \rightarrow 6p_{1/2,3/2} \) transition matrix elements, and \( W_F \) are defined by Eq. (6). The partial derivatives denote the ratio of the changes in the reduced matrix elements and binding energies. In the present calculations, we repeat the calculations of these derivatives many times, each time using a slightly different polarization potential (with the change of binding energy in the range \( 10^{-9} \) to \( 10^{-5} \) a.u.). Table VIII lists the average values of these partial derivatives and the corresponding uncertainties that are determined as root-mean-squares (rms) of the differences from the average values. Then, the dipole polarizabilities for the hyperfine states are further determined by using these partial derivatives.

Table IX lists the dipole scalar and tensor polarizabilities of the hyperfine components of the ground level of \(^{133}\)Cs. The uncertainties are derived from the uncertainties of the partial derivatives in Table VIII. The tensor polarizabilities of the hyperfine states are found to be \( 10^{-4} \) in magnitude. As far as we know, there are no other theoretical or experimental results for direct comparison. Nevertheless, we can compare the present hyperfine Stark shift of the ground states with other available results. It is often reported in experiment as a hyperfine Stark shift coefficient \( k \) (in Hz/(V/m)), i.e., \( k = -0.5 \Delta \alpha / \alpha \) with the difference \( \Delta \alpha \) in the scalar polarizabilities of the hyperfine components \( F=4 \) and \( F=3 \) of the ground level. Table X lists the hyperfine Stark shift coefficient \( k \) and \( \Delta \alpha \). As can be seen from this table, the

### Table VIII. Partial derivatives (in a.u.) of the matrix elements of the \( 6s_{1/2} \rightarrow 6p_{1/2,3/2} \) transitions with respect to the initial- and final-state binding energies. The uncertainties are given in parentheses.

| Transitions | \( \partial E \) | \( \partial F \) |
|-------------|----------------|----------------|
| \( 6s_{1/2} \rightarrow 6p_{1/2} \) | 34.82(42) | -0.98(4) |
| \( 6s_{1/2} \rightarrow 6p_{3/2} \) | 51.76(62) | -7.50(30) |

### B. Dipole polarizabilities

The calculation of dipole scalar polarizabilities for the hyperfine states is rather similar to Eq. (6), except that \( J_0 \) should be replaced by the hyperfine oscillator strengths \( f_{g\to i}^\text{hf} \), and \( \Delta E_{0\to n} \) is replaced by the hyperfine transition energy \( \Delta E_{g\to i} \). Likewise, the calculation of hyperfine absorption oscillator strength \( f_{g\to i}^\text{hf} \) is similar to Eq. (6) except that \( J_0 \) should be replaced by \( F \) and the matrix element is replaced by Eq. (11). Because the total angular momentum of the hyperfine components of the ground level is greater than one, the corresponding dipole polarizability has a tensor component, which can be written as

\[
\alpha = 6 \left( \frac{5F_g(2F_g-1)(2F_g+1)}{6(F_g+1)(2F_g+3)} \right) ^{1/2} \times \sum_i (-1)^{F_g+i} \begin{pmatrix} F_g & 1 & F_i \\ 1 & F_g & 2 \end{pmatrix} \frac{\Delta E_{g\to i}}{\Delta E_{g\to i}^2 - \omega^2}. \tag{12}
\]
TABLE IX. Dipole scalar $\alpha^S$ and tensor $\alpha^T$ polarizabilities of the hyperfine components of the ground level of $^{133}$Cs. The uncertainties are given in parentheses. $[a\ b]$ represents $a \times 10^b$.

| States  | $F$ | $\alpha^S$ (a.u.) | $\alpha^T$ (a.u.) |
|---------|-----|-------------------|-------------------|
| $6s_{1/2}$ | 3   | 4.0066237(3)      | 1.2263(24)[-4]   |
| $6s_{1/2}$ | 4   | 4.0068105(3)      | -2.2919(45)[-4]  |

TABLE X. Hyperfine Stark shift coefficients $k$ (in Hz/(V/m)$^2$) and the differences $\Delta \alpha$ (in a.u.) in the scalar polarizabilities of the hyperfine components of the ground level $F=4$ and $F=3$. The unit Hz/(V/m)$^2$ can be converted into a.u. by multiplying $0.4018778 \times 10^9$. The uncertainties are given in parentheses.

| $ab\ initio$ [85] | 0.01817(16)      | -2.26(2)                |
| Relativistic many-body [92] | 0.018253(65) | -2.27(1)               |
| Perturbation theory [93] | 0.01656(8) | -2.06(1)               |
| Expt. [86]    | 0.01841(56)      | -2.29(7)                |
| Expt. [87]    | 0.01809(40)      | -2.25(5)                |
| Expt. [88]    | 0.01744(209)     | -2.17(26)               |
| Expt. [89]    | 0.018253(32)     | -2.27(2)                |
| Expt. [90]    | 0.01519 (96)     | -1.89(12)               |
| Expt. [91]    | 0.01632(32)      | -2.03(4)                |

The present hyperfine Stark shift agrees very well with other experimental [80, 91] and theoretical results [81, 82].

The correction of Eq. (14) to the $6s_{1/2} \rightarrow 6p_{1/2}$ transition matrix elements is very significant for the result of the hyperfine Stark shift. The $\Delta \alpha$ without considering the correction of the transition matrix elements is just $-0.01013$ a.u. That is, the correction of the $6s_{1/2} \rightarrow 6p_{1/2}$ transition matrix elements makes the hyperfine Stark shift increase by about 85%.

C. Tune-out wavelengths

By means of the hyperfine energy levels and matrix elements obtained above, the dynamic polarizabilities and tune-out wavelengths of the hyperfine components of the ground level can be further determined. Table XI lists the tune-out wavelengths of the hyperfine components of the ground level of $^{133}$Cs, in which the tensor contribution is not considered. Two new features of the tune-out wavelengths are found for the hyperfine splitting. One of them is that the hyperfine splitting of the ground state results in two sets of tune-out wavelengths; one is for the $6s_{1/2}, F = 3$ state, and the other is for the $6s_{1/2}, F = 4$ state. Another feature is that the hyperfine splitting of the $np_j$ states results in additional tune-out wavelengths. The tune-out wavelengths near 894 nm and 852 nm are located between the hyperfine components of the transitions from the $6p_{1/2}$ and $6p_{3/2}$ levels to the ground level, respectively, while the ones near 459 nm and 455 nm are located between the hyperfine components of the transitions from the $7p_{1/2}$ and $7p_{3/2}$ levels to the ground level, respectively. These tune-out wavelengths would be difficult to be measured in experiments due to very small energy splittings of the hyperfine states. The tune-out wavelength near 880 nm is the first primary tune-out wavelength, which lies between the excitation thresholds of the $6p_{1/2}$ and $6p_{3/2}$ states. The primary tune-out wavelength 880.200852 nm of the $6s_{1/2}, F = 3$ state is shorter than the 880.2144 nm tune-out wavelength of the $6s_{1/2}$ state by about 0.013548 nm. The tune-out wavelength 880.225025 nm of the $6s_{1/2}, F = 4$ state is longer than the 880.2144 nm tune-out wavelength of the $6s_{1/2}$ state by about 0.010625 nm. As can be seen from Table XI the energy shifts of the first primary tune-out wavelengths for the $6s_{1/2}, F = 3, 4$ states are $7.997 \times 10^{-7}$ a.u. and $-6.219 \times 10^{-7}$ a.u., respectively. These shifts correspond very closely to the hyperfine interaction energies of the $6s_{1/2}$ state. The tune-out wavelengths near 460 nm and 457 nm are also primary tune-out wavelengths, which lie between the excitation thresholds of the $6p_{3/2}$ and $7p_{1/2}$ states and the thresholds of the $7p_{1/2}$ and $7p_{3/2}$ states, respectively. The energy shifts of the tune-out wavelengths are also very close to the hyperfine interaction energy of the ground state.

While the calculations of the hyperfine Stark shift are critically reliant on the use of the energy-adjusted reduced dipole matrix elements, this is not true for the tune-out wavelengths. For example, the difference of the tune-out wavelengths near 880 nm with and without considering the correction to the $6s_{1/2} \rightarrow 6p_{1/2/2}$ transition matrix elements are only $-8.5 \times 10^{-5}$ nm and $-6 \times 10^{-6}$ nm for the $F = 3$ and $F = 4$ states, respectively. The influence of the correction to the transition matrix elements on the tune-out wavelengths can be ignored.

If tensor polarizabilities are considered, the tune-out wavelengths also depend on the magnetic sublevels. Table XII lists the primary tune-out wavelengths for the magnetic sublevels of the $6s_{1/2}, F = 3$ and $F = 4$ states of $^{133}$Cs. The differences of the tune-out wavelengths with and without considering the tensor contributions are also listed in Table XI. It is found that the differences in these tune-out wavelengths for any of the magnetic sublevels are $10^{-5} \sim 10^{-6}$ nm. If the tune-out wavelengths could be measured at a level of fm, the contribution of the tensor polarizabilities to the tune-out wavelengths could be extracted from experiments.

IV. REMARKS ON UNCERTAINTY OF THE PRESENT RESULTS

The uncertainties of the present transition matrix elements $T_{RCICP}$ given in Table III are estimated very carefully. Similar to the method used in Ref. [94], in
TABLE XI. FIG. 2. Natural logarithm of the ratio, ln($T_{\text{Ref}}/T_{\text{RCICP}}$).

which the oscillator strengths are classified into different groups based on the deviations from best experimental data, the uncertainties of the RCICP transition matrix elements are evaluated by comparing with the most accurate experimental or theoretical results $T_{\text{Ref}}$ listed in bold in Table III. FIG. 2 plots the natural logarithm of the ratio, ln($T_{\text{Ref}}/T_{\text{RCICP}}$). As shown in this figure, the matrix elements of all the involved transitions can be classified into four groups. The first group is those with the $T_{\text{RCICP}}$ larger than 3.0 a.u., which consists of the $6s_{1/2} \rightarrow 6p_{1/2,3/2}$, $7s_{1/2} \rightarrow 6p_{1/2,3/2}$, and $7s_{1/2} \rightarrow 7p_{1/2,3/2}$ transitions. These transition matrix elements are calculated very accurately. The uncertainty estimated by the rms of the difference from the reference values is about 0.17% for this group. The second group is those with the $T_{\text{RCICP}}$ in the range 0.9–3.0 a.u., including the $7s_{1/2} \rightarrow 8p_{1/2,3/2}$ transitions. The uncertainty for this group is about 0.6%. The third group is those with the $T_{\text{RCICP}}$ in the range 0.25–0.9 a.u., including the $6s_{1/2} \rightarrow 7p_{1/2,3/2}$ and $7s_{1/2} \rightarrow 9p_{1/2,3/2}$ transitions. The uncertainty is about 2%. The fourth group is those with the $T_{\text{RCICP}}$ smaller than 0.25 a.u., including the $6s_{1/2} \rightarrow 8p_{1/2,3/2}$ transitions. The uncertainty is about 3.6%. It should be mentioned that the uncertainties given above are estimated on the level of one standard deviation.

However, the uncertainties of the tune-out wavelengths need to be specially considered due to different transition contributions. For the tune-out wavelength near 880 nm,
its calculation can be simplified as

\[
0 = \frac{f_{6s_{1/2} \rightarrow 6p_{1/2}}}{(\Delta E_{6s_{1/2} \rightarrow 6p_{1/2}})^2} \left[ \frac{f_{6s_{1/2} \rightarrow 6p_{1/2}}}{(\Delta E_{6s_{1/2} \rightarrow 6p_{1/2}})^2} \frac{R_{6p}(1+\delta_{6p})}{(1+\delta_{6p})^2} \frac{\alpha_{\text{rem}}(\omega)}{\Delta E_{6s_{1/2} \rightarrow 6p_{1/2}}^2} \right] + \alpha_{\text{rem}}(\omega),
\]

(15)

Here, \( R_{6p} = |(6s_{1/2}|D|6p_{3/2})|^2/(|6s_{1/2}|D|6p_{1/2})|^2 \), and \( \alpha_{\text{rem}}(\omega) \) is the remainder part (exclude the \( 6s_{1/2} \rightarrow 6p_{1/2,3/2} \)) of dynamic dipole polarizability. The energy difference \( \Delta E_{6p_{3/2}}^p \) can be expressed as \( \Delta E_{6p_{3/2}}^p = \Delta E_{6p_{1/2}}^p + (1+\delta_{6p})^2 \) with \( \delta_{6p} = 0.0495639 \). As seen from Eq. (15), there are three sources of the uncertainty for this tune-out wavelength. The first source is the uncertainty of the \( 6s_{1/2} \rightarrow 6p_{1/2} \) reduced matrix element or oscillator strengths. The uncertainty 0.17% of the \( 6s_{1/2} \rightarrow 6p_{1/2} \) matrix elements may lead to an uncertainty of 0.0004 nm for the 880-nm tune-out wavelength. The second one is the uncertainty of the line strength ratio \( R_{6p} \). We find that this tune-out wavelength is very sensitive to the ratio \( R_{6p} \). The uncertainty of the RCICP ratio \( R_{6p} = 1.9844(100) \) leads to an uncertainty of 0.0475 nm for this tune-out wavelength. The third one is the uncertainty of the \( \alpha_{\text{rem}}(\omega) \). The uncertainty of the \( \alpha_{\text{rem}}(\omega) \), which includes the uncertainties of the \( \alpha_{\text{core}} \) and transitions from more highly-excited states (assumed to be 10% uncertainty), may lead to an uncertainty of 0.0005 nm for this tune-out wavelength. By comparing the above estimations, it can be found that the total uncertainty of the 880-nm tune-out wavelength is mainly determined by the uncertainty of the \( R_{6p} \), and the uncertainties from the uncertainties of the \( 6s_{1/2} \rightarrow 6p_{1/2} \) transition matrix element and \( \alpha_{\text{rem}}(\omega) \) are negligible. For the 880-nm \( \lambda_{\text{zero}}^{rcom} \), the uncertainty of the experimental line strength ratio \( R_{6p} = 1.9768(33) \) leads to an uncertainty of 0.0158 nm, which is about one third of the uncertainty of the RCICP tune-out wavelength.

Moreover, as for the tune-out wavelengths near 460 nm and 457 nm, both of them are caused by a cancellation of the \( 6s_{1/2} \rightarrow 6p_{1/2,3/2} \) and \( 6s_{1/2} \rightarrow 7p_{1/2,3/2} \) transitions. The corresponding calculation can be simplified as

\[
0 = \alpha_{6p}(\omega) + \frac{f_{6s_{1/2} \rightarrow 7p_{1/2}}}{(\Delta E_{6s_{1/2} \rightarrow 7p_{1/2}})^2} \left[ \frac{f_{6s_{1/2} \rightarrow 7p_{1/2}}}{(\Delta E_{6s_{1/2} \rightarrow 7p_{1/2}})^2} \frac{R_{7p}(1+\delta_{7p})}{(1+\delta_{7p})^2} \frac{\alpha'_{\text{rem}}(\omega)}{\Delta E_{6s_{1/2} \rightarrow 7p_{1/2}}^2} \right] + \alpha'_{\text{rem}}(\omega),
\]

(16)

where \( R_{7p} = |(6s_{1/2}|D|7p_{3/2})|^2/(|6s_{1/2}|D|7p_{1/2})|^2 \), \( \alpha'_{\text{rem}}(\omega) \) is the remainder part (exclude the \( 6s_{1/2} \rightarrow 6p_{1/2,3/2} \) and \( 6s_{1/2} \rightarrow 7p_{1/2,3/2} \)) of dynamic dipole polarizability. The polarizability \( \alpha_{6p}(\omega) \) corresponding to the \( 6s_{1/2} \rightarrow 6p_{1/2,3/2} \) transitions is retained as a separate term since it is much larger than the remainder term. The uncertainty analysis of these two tune-out wavelengths is similar to the analysis of the 880-nm tune-out wavelength. The uncertainties of the RCICP \( \alpha_{6p}(\omega) \) and the \( 6s_{1/2} \rightarrow 7p_{1/2} \) matrix elements lead to the uncertainties of 0.0043 nm and 0.0468 nm for these tune-out wavelengths. The uncertainty of the RCICP ratio \( R_{7p} = 4.3474(2463) \) leads to the uncertainties of 0.0271 nm and 0.0783 nm for 460-nm and 457-nm tune-out wavelengths, respectively. Consequently, the total uncertainties (arithmetic square root of the sum of squares of those uncertainties) of the RCICP 460-nm and 457-nm tune-out wavelength are estimated to be about 0.0543 nm and 0.0917 nm. However, for the 460-nm and 457-nm \( \lambda_{\text{zero}}^{rcom} \), the uncertainty of the experimental \( \alpha_{6p}(\omega) \), which were derived from the uncertainty of the experimental transition matrix elements of the \( 6s_{1/2} \rightarrow 6p_{1/2,3/2} \) leads to an uncertainty of 0.0014 nm. The uncertainty of the \( 6s_{1/2} \rightarrow 7p_{1/2} \) matrix element makes an uncertainty of 0.0039 nm. The experimental ratio \( R_{7p} = 4.2626(396) \) leads to the uncertainties of 0.0047 nm and 0.0132 nm for the 460-nm and 457-nm \( \lambda_{\text{zero}}^{rcom} \), respectively. As a result, the total uncertainties of the 460-nm and 457-nm \( \lambda_{\text{zero}}^{rcom} \) are about 0.0063 nm and 0.0171 nm.

Apart from the uncertainty corresponding to the fine-structure states, the uncertainty of tune-out wavelengths of the hyperfine states should be stated as well. The source of the uncertainties of the tune-out wavelengths for the hyperfine components of the ground level should include two parts. The first part is from the uncertainties of the matrix elements in Table III. The uncertainties for the primary tune-out wavelengths (near 880, 460 and 457 nm) derived from this part are expected to be at the same level as those of the tune-out wavelengths of the fine-structure \( 6s_{1/2} \) state. The second part is from the uncertainties of the partial derivatives in Table VIII. This part is the main source for the uncertainties of the tune-out wavelength shifts \( \Delta \lambda \) in Table XI. In order to show the uncertainties of the \( \Delta \lambda \), Table XI lists the uncertainties that are derived from the uncertainties of the partial derivatives. However, for the tune-out wavelengths near the 894, 852, 459 and 455 nm, which are located between the transition energies from the hyperfine components of the \( 6p_{1/2}, 6p_{3/2}, 7p_{1/2} \) and \( 7p_{3/2} \) to the \( 6s_{1/2} \) \( F = 3 \) (or \( F = 4 \)) levels, the uncertainties are estimated to be less than \( 10^{-7} \) nm.

V. CONCLUSION

The energy levels, E1 transition matrix elements, static and dynamic polarizabilities corresponding to the \( 6s_{1/2} \) state of Cs atoms are calculated by using the RCICP approach. Three longest tune-out wavelengths of the \( 6s_{1/2} \) state are determined. It has been found that the present RCICP results agree very well with other available experimental and theoretical results.

Apart from the fine-structure \( 6s_{1/2} \) state, in particular, we consider the effect of the hyperfine splittings of the \( 6s_{1/2}, 6p_{j}, \) and \( 7p_{j} \) states of \( ^{133}\text{Cs} \) atoms. The dynamic polarizabilities and tune-out wavelengths of the hyperfine components of the ground level of \( ^{133}\text{Cs} \) atoms are further determined. The tune-out wavelengths corresponding to the hyperfine splittings of the \( np \) states are hard to be measured. However, all of the obtained primary tune-out wavelengths have relatively large hyper-
fine shifts. For example, the shifts of the 880-nm tune-out wavelength corresponding to the 6s1/2, F = 3 and F = 4 states are about −0.0135 nm and 0.0106 nm, respectively; they are very close to the hyperfine interaction energies. Such large shifts can be resolved in experiments. If the tune-out wavelengths could be measured at a level of fm, the contribution of the tensor polarizabilities of the hyperfine components of the ground level to the tune-out wavelengths could be extracted from experiments. In addition, the 880-nm tune-out wavelength is found to be very sensitive to the ratio of the line strengths of the 6s1/2 → 6p1/2,3/2 transitions. Accurate measurements on this tune-out wavelength would enable a high-precision determination of the 6s1/2 → 6p1/2,3/2 line strength ratio.
