INTRODUCTION

Rabbit as an animal model have been widely used for experimental researches. Coccidiosis is one of the most important diseases in rabbit breeding, which is a highly contagious infection and caused by several species of Eimeria [1]. Eimeria stiedae is one of the most pathogenic species in domestic rabbits [2]. E. stiedae parasitizes the bile duct epithelial cells which causes severe liver coccidiosis, resulting in enormous economic losses [3]. General clinical symptoms include reduced food consumption, slow growth, diarrhea, and even death of a large number of rabbits [4,5].

Because no vaccines are yet available, the control of rabbit coccidiosis is primarily based on careful management combined with prophylactic medication in feed or water [6]. However, the present methods for the control of rabbit coccidiosis face the problems of the rise of drug resistance, high cost of new drug development, and societal pressure against use of the chemicals [7-9]. These have prompted the development of new control strategies against rabbit coccidiosis, and an efficient vaccine that can prevent rabbit coccidiosis is urgently needed. Recent efforts are therefore directed towards the development of recombinant vaccines against rabbit coccidiosis [10-12]. Immunoproteomic analysis is a powerful technique for high-throughput detection to identify novel potential antigens from the sporozoites of Eimeria stiedae. Protein spots were recognized by the sera of New Zealand rabbits infected artificially with E. stiedae. The proteins were characterized by matrix-assisted laser desorption ionization time of flight mass spectrometry (MALDI-TOF/TOF-MS) analysis in combination with bioinformatics. Approximately 868 protein spots were detected by silver-staining, and a total of 41 immunoreactive protein spots were recognized by anti-E. stiedae sera. Finally, 23 protein spots were successfully identified. The proteins such as heat shock protein 70 and aspartyl protease may have potential as immunodiagnostic or vaccine antigens. The immunoreactive proteins were found to possess a wide range of biological functions. This study is the first to report the proteins recognized by sera of infected rabbits with E. stiedae, which might be helpful in identifying potential targets for vaccine development to control rabbit coccidiosis.

Key words: Eimeria stiedae, rabbit, sporozoite, immunoproteomics, vaccine target

MATERIALS AND METHODS

Collections of parasites and immune sera
Oocysts of E. stiedae (Jiangsu strain) were propagated and maintained by passage through coccidian-free New Zealand
rabbits in the Laboratory Animal Center of Nantong University, Nantong, China. Oocysts were purified from the livers of infected rabbits by floating in sucrose solution and were enumerated by hemocytometer. All animal experiments were performed in compliance with the Institutional Animal Care and Use Committee of Nantong University and national regulations and policies (no. 20150605–001).

Twelve 6-week-old healthy New Zealand rabbits, weighing 1–1.5 kg were used. Six New Zealand rabbits reared coccidian-free were orally infected with individual doses of $1 \times 10^4$ sporulated oocysts of *E. stiedae*. The rabbits were challenged 3 times at 2-week intervals with 5,000 sporulated oocysts per rabbit. Blood samples were obtained from rabbits by cardiac puncture 2 weeks after the last infection. Sera were collected from the samples, aliquoted, and stored at -80°C until used. Six unchallenged rabbits were reared in the same condition. All rabbits were fed ad libitum and free water. A cycle of 12-hr light and 12-hr dark was used throughout the experiment.

### Preparation of protein extracts and 2-dimensional gel electrophoresis (2-DE)

Sporozoites of *E. stiedae* were purified from sporulated oocysts, and soluble proteins were prepared as described previously [13,18]. Briefly, the sporulated oocysts were sonicated in an ice box, and the pellet was resuspended in a lysis buffer. Sporozoites were excysted and then purified on a cotton column (2 cm) to eliminate encysted sporozoites and oocysts. The sporozoite pellet was then concentrated and purified with the ReadyPrep 2-D Cleanup Kit (Bio-Rad, Hercules, California, USA). Protein concentration was determined by the Bradford method using Bio-Rad protein assay (Bio-Rad). Samples of aliquots were stored at -80°C until use.

The purified proteins (200 μg) were separated by isoelectric focusing (IEF) on non-linear IEF strips (pH 3–10; 13 cm) (GE Healthcare, Little Chalfont, UK). The IEF was carried out under the following step: 500 V for 1 hr, 1,000 V for 1 hr, then 8,000 V for 10 hr to reach a total of 60,000 Vh. After completion of IEF, the second dimensional separation was carried in 12.5% polyacrylamide gel using the Multiphor system (Amersham Biosciences, Amersham, UK). Gels were fixed overnight in a fixing solution and stained by the silver-staining method. Each sample was repeated 3 times.

### Immunoblot analysis and in-gel digestion

Immunoblot analysis and in-gel digestion was performed by a semi-dry transfer system as previously described [19]. Briefly, the membranes were blocked with 5% W/V skim milk in 0.05% Tween-20 PBS, incubated with anti-*E. stiedae* serum of rabbit diluted 1:500 in blocking buffer and then horseradish peroxidase-conjugated goat anti-rabbit antibody (BioRad) diluted at 1:2,500. The immunoreactive proteins were visualized and analyzed by autoradiography using enhanced chemiluminescence reagent (Pierce Biotechnology, Rockford, Illinois, USA) and ImageMaster 2D Platinum software (Version 7.0. Amersham Bioscience, Swiss Institute of Bioinformatics, Geneva, Switzerland). Normal rabbit serum was used to test another blotting membrane as a negative control. Western blot analysis was repeated 3 times. The immunogenic spots were selected, and in-gel digestion was performed with trypsin.

### Protein identification and gene ontology (GO) analysis

In-gel digestion products were sent to Shanghai Applied Protein Technology Co. Ltd. for analysis by MALDI-TOF/TOF-MS (ABI Voyager DE Pro, Applied Biosystems). Sequences of identified proteins were submitted to a BLAST server (http://www.ncbi.nlm.nih.gov/BLAST/) for a homology search. GO analysis for characterized proteins based on BLAST results was carried out using Blast2GO version 2.7.2. The identified proteins were categorized through a InterProScan InterProScan software. The results were subjected to analyze by GO categories using the Web Gene Ontology Annotation Plotting (WEGO, http://wego.genomics.org.cn/cgi-bin/wego/index.pl).

### RESULTS

#### 2-DE profiles of *E. stiedae* sporozoites

Proteins from the sporozoites of *E. stiedae* were separated by 2-DE to find immunogenic proteins. The protein profiles of *E. stiedae* sporozoites extracts were well represented by 2-DE separations across a pH 3-10 gradient. About 868 protein spots were obtained on the 2-DE maps constructed with silver-stained gels and analyzed by ImageMaster 2D Platinum software (Fig. 1).

Western blot analysis of sporozoite proteins of *E. stiedae* from 2-DE

To evaluate the immunity of *E. stiedae* sporozoite proteins, western blot assay was conducted with anti-*E. stiedae* sera obtained from infected rabbits. Approximately 291 spots were shown on western blot maps of the sporozoites of *E. stiedae*
Song et al.: Potential vaccine targets against rabbit coccidiosis

(Fig. 2A), whereas none were detected on the negative-control sera (Fig. 2B).

Immunoreactive protein analysis and identification by NCBI database

Forty-one protein spots were shown to be highly matched to those from the sporozoites of *E. stiedae* in the preparative 2-DE (Fig. 2A). The parameters, including the probability score for the match, isoelectric point (pI), molecular weight (MW), and the number of peptide matches, were used for confident protein identification.

The results displayed that spots 227, 248, 289, and 321 were identified as heat shock protein of *Eimeria*. The spot 178 was identified as a merozoite surface protein of *Plasmodium*. The spot 158 was identified as an ATP-dependent RNA helicase of *Eimeria brunetti*, and the spot 309 was identified as an eukaryotic aspartyl protease of *Eimeria maxima*. The spot 249 was identified as the SICA antigen of *Plasmodium knowlesi*. Two proteins (spot 987 and 1070) were identified as prefolding subunit 6 of *Hammondia hammondi*. Several spots were identified as hypothetical proteins of *Toxoplasma*, *Eimeria*, and *Plasmodium*. Two spots (838 and 865) were identified as homologous proteins (sperm-tail PG-rich repeat protein and repeat-containing protein) to other protozoan parasites (*Tetrahymena thermophila* and *Stylonychia lemnae*). In total, 23 protein spots were successfully identified by MALDI-TOF/TOF-MS (Table 1).

Functional categorization of immunoreactive proteins by GO

To further study the biological functions of the 23 immunoreactive proteins, GO annotation was carried out. Annotated relevant parasite proteins from the NCBI database were analyzed by Blast2GO based on BLASTP search. Proteins identified in this study were further categorized by their cellular component, molecular function, and biological process using WEGO. These proteins were classified into 2 categories, includ-

**DISCUSSION**

The rabbit (*Oryctolagus cuniculus*) is a valuable animal species widely used for biomedical research purposes, meat, and fur production [23]. However, coccidiosis is common in rabbits and considered a severe problem leading to a large economic loss. Duszynski and Couch [24] reported that the rate of coccidiosis infection ranged from 64% to 100% in the world. According to a report, China is the largest rabbit-producing country, which produced approximately 700 million of rabbit in 2013 and the year-over-year percentage increase was about 2% [25]. Previous reports showed that the infection rate of coccidia in the surveyed experimental rabbits was up to 100% in China [26].

In order to overcome the above-mentioned drawbacks of the current methods to control coccidiosis, researches have focused on novel strategies based on recombinant vaccination as a potential alternative method of coccidiosis control [27,28]. Char-
characterization of specific antigens of *Eimeria* is a pivotal step in development of a recombinant coccidial vaccine. In recent years, employing a combination of 2-DE, immunoblotting, and mass spectrometric analysis has proved to be a powerful approach to identify novel antigens [29]. Right now, there is a wide array of immunogenic antigens from *E. tenella* sporozoites and merozoites characterized by an immunoproteomics method [30,31]. *E. tenella* antigens, such as sporozoite antigen, immunoglobulin heavy chain protein, heat shock protein 70 (HSP70), pyruvate kinase, enolase, eimepsine, and lactate dehydrogenase were identified as immunogenic antigens [18,19].

To our knowledge, there were few reports on rabbit coccidiosis, especially those focused on identification of novel antigens of *E. stiedae*. In this study, we report for the first time an immunoproteomic analysis of sporozoite proteins of *E. stiedae* from infected rabbits. Using immunoproteomic analysis, a total of 41 immunoreactive protein spots were recognized by anti-*E. stiedae* sera of infected rabbits, and 23 protein spots were successfully identified by MALDI-TOF/TOF-MS. Of the 23 analyzed spots, 7 proteins belonged to the family Eimeriidae. Four spots (spot 248, 289, 227, and 321) were identified as HSP70 of *Eimeria*, 2 of which were at similar Mr and pl values as their orthologues in *Eimeria praecox*, while the other 2 were from *E. necatric* and *E. brunetti*. HSP70 is considered to be from a predominant HSP family and plays a key regulatory role in parasite development and pathogenesis [32]. It is a highly abundant protein in apicomplexan parasites and is often detected in proteomics studies [33,34]. Liu et al. [19] reported that a protein matching HSP70 of *Eimeria acervulina* was identified by immunoproteomic analysis from a second-generation proteomic analysis [36]. Spots 183, 547, 71, and 331 were identified as hypothetical proteins of *T. gondii* with unknown function not described previously at the protein level. Another 6 hypothetical proteins also showed immunoreactivity to *E. stiedae* positive antisera. The biological characteristics of these proteins remain to be identified.
