We study the generalization of S-duality to non-commutative gauge theories. For rank one theories, we obtain the leading terms of the dual theory by Legendre transforming the Lagrangian of the non-commutative theory expressed in terms of a commutative gauge field. The dual description is weakly coupled when the original theory is strongly coupled if we appropriately scale the non-commutativity parameter. However, the dual theory appears to be non-commutative in space-time when the original theory is non-commutative in space. This suggests that locality in time for non-commutative theories is an artifact of perturbation theory.
1. Introduction

Non-commutative gauge theory [1] provides an interesting class of examples in which to explore the effects of spatial non-locality. While it is easy to define the classical non-commutative gauge theory, it is much harder to determine whether the quantum theory exists. Since non-commutative gauge theories arise in particular string theory backgrounds, we know that these theories can be embedded consistently in string theory. The decoupling argument of Seiberg and Witten [2] suggests that some of these theories might exist as quantum theories independent of string theory.

We are primarily interested in four-dimensional gauge theories. Our goal is to understand how S-duality [3,4] generalizes to non-commutative gauge theory. The generalization is not a straightforward consequence of S-duality in type IIB string theory. To see this, let us begin by briefly recalling how S-duality of N=4 Yang-Mills arises from string theory. In the limit $\alpha' \to 0$, the theory on coincident D3-branes is N=4 Yang-Mills. For simplicity, we set the RR scalar $C^{(0)}$ to zero. The gauge theory coupling constant, $g^2$, is then related to the closed string coupling constant $g_s = e^\phi$:

$$
\frac{g^2}{4\pi} = g_s. \tag{1.1}
$$

The conjectured $SL(2, \mathbb{Z})$ symmetry of string theory then descends to an $SL(2, \mathbb{Z})$ symmetry of the field theory.

To obtain non-commutative Yang-Mills, we consider a system of coincident D3-branes with NS-NS $B$-field non-zero along the brane. In the decoupling limit [2], the theory on the brane has a coupling constant related to the open string coupling constant, $G_s$, rather than the closed string coupling:

$$
g^2 = 2\pi G_s. \tag{1.2}
$$

In the decoupling limit, the closed string coupling constant goes to zero while $G_s$ remains finite and dependent on the $B$-field. In this case, S-duality of the closed string theory does not descend to a symmetry of the field theory.

For a $U(1)$ gauge theory, S-duality can be demonstrated directly with a purely field theoretic argument. We start with the Minkowski space action,[3]

$$
S = -\int \frac{1}{4g^2} F \wedge \ast F, \tag{1.3}
$$

---

1 We use $\ast$ to denote the Hodge dual of a form rather than the star product.
where \( F = dA \) is the field strength. We want to perform a Legendre transformation with respect to \( F \). To implement the Bianchi identity,

\[
dF = 0,
\]

we introduce a dual gauge-field \( A_D \),

\[
S = - \int \left( \frac{1}{4g^2} F \wedge \ast F + \frac{1}{2} A_D \wedge dF \right).
\]  

(1.4)

We can now treat \( F \) as an independent variable and perform the path-integral over \( F \). This amounts to solving the field equations for \( F \) which gives the relation,

\[
dA_D = \frac{1}{g^2} \ast F,
\]

(1.5)

and the resulting dual action,

\[
S = - \int \frac{g^2}{4} F_D \wedge \ast F_D.
\]  

(1.6)

The aim of this discussion is to generalize this purely field theoretic argument to the non-commutative rank one theory. Unlike ordinary abelian gauge theory, the coupling constant cannot be scaled away even for the rank one non-commutative theory.

In the following section, we explicitly show that the non-commutative action expressed in terms of a commutative gauge-field contains only powers of \( F \) to order \( \theta^2 \). In particular, the gauge-field does not appear explicitly. It is not hard to argue that this must be true to all orders in \( \theta \). This implies that we can obtain a dual description by Legendre transforming with respect to \( F \). The resulting dual theory is classical since we neglect loops. However, to order \( \theta \), we will see that no loops appear and the quantum and semi-classical dual descriptions agree. To order \( \theta^2 \), loops appear and the bosonic theory needs to be regulated. At this point, the computation should be performed in the full \( N=4 \) theory.

Fortunately, our primary observations are already visible at order \( \theta \). We find that under the duality transformation,

\[
\theta \rightarrow \tilde{\theta} = g^2(\ast \theta).
\]  

(1.7)

That this transformation does not square to one is not so surprising since \( (S)^2 \) is not the identity operation but charge conjugation. We will also find that \( \tilde{\theta} \) must be held fixed if the dual theory is to have a perturbative expansion in \( 1/g \). Even more interesting is
the observation that if $\theta$ is purely spatial then $\tilde{\theta}$ involves a space direction and a time direction. The theory becomes non-commutative in space-time. Although we will not obtain the complete quantum dual description, it seems clear that this feature, visible at leading order in $\theta$, persists to higher orders. Space-time non-commutative theories are highly unusual; see [5] for a recent discussion. Our results suggest that we cannot avoid studying these theories if we are to understand theories which perturbatively have only spatial non-commutativity.

2. The Duality Transformation

2.1. Rewriting the non-commutative Lagrangian

The non-commutative theory is defined by the action,

$$S = -\frac{1}{4g^2} \int \hat{F} \wedge \ast \hat{F}. \quad (2.1)$$

The change of variables given in [2] allows us to express $\hat{F}$ in terms of a commutative gauge-field $A$. We assume that $\theta$ is purely spatial. The relation takes the form,

$$\hat{F} = F + T_\theta(A) + T_{\theta^2}(A) + \ldots. \quad (2.2)$$

The terms of order $\theta$ are given by,

$$T_\theta(A) = -F \theta F - A_k \theta^{kl} \partial_l F. \quad (2.3)$$

We follow the notation of [3] where $F \theta F = F_{ik} \theta^{kl} F_{kj}$. The expression for $T_{\theta^2}(A)$ is found in [3],

$$T_{\theta^2}(A) = F \theta F \theta F + \frac{1}{2} A_k \theta^{kl} (\partial_l A_m + F_{lm}) \theta^{mn} \partial_n F$$

$$+ \theta^{kl} A_k \partial_l (F \theta F) + \frac{1}{2} \theta^{kl} \theta^{mn} A_k A_m \partial_l \partial_n F. \quad (2.4)$$

The expression for $\hat{F}$ explicitly contains $A$. However, we can manipulate the action (2.1) so that it takes the following form,

$$S = -\frac{1}{4g^2} \int (F \wedge \ast F + L_\theta(F) + L_{\theta^2}(F) + \ldots). \quad (2.5)$$

The terms of order $\theta$ take the form,

$$L_\theta(F) = 2 \text{tr}(\theta F^3) - \frac{1}{2} \text{tr}(\theta F) \text{tr}(F^2), \quad (2.6)$$
where we define $\text{tr}(AB) = A_{ij}B^{ji}$. Since our theory is rank one, there should be no confusion with traces over group indices. It is not too hard to find an expression for $L_{\theta^2}(F)$ which takes the form:

$$L_{\theta^2}(F) = -2\text{tr}(\theta F \theta F^3) + \text{tr}(\theta F^2 \theta F^2) + \text{tr}(\theta F) \text{tr}(\theta F^3) - \frac{1}{8}\text{tr}(\theta F)^2 \text{tr}(F^2) + \frac{1}{4}\text{tr}(\theta F \theta F) \text{tr}(F^2).$$ (2.7)

While we have explicitly demonstrated that it is possible to express (2.1) in terms of $F$ to order $\theta^2$, it must be the case to all orders in $\theta$. The only gauge-invariant operator that can be constructed from $A$ is $F$. While $\hat{F}$ can depend on $A$ explicitly, the action must be gauge-invariant under the commutative gauge-invariance. This requires that the action be expressible in terms of $F$ alone.

### 2.2. Duality at $O(\theta)$

Since the action can be expressed in terms of $F$, we can implement a duality transformation in essentially the way described in the introduction. To perform the Legendre transform, we shift the action as before

$$S \rightarrow S + \int \frac{1}{2} A_D \wedge dF. \quad (2.8)$$

The equation of motion for $F$ gives,

$$g^2 F_D = *F + \frac{1}{2} \delta L_{\theta} \frac{\delta F}{\delta F} (F) + O(\theta^2). \quad (2.9)$$

To lowest order in $\theta$, we can solve for $F$ in terms of $F_D$:

$$*F = g^2 F_D - \frac{1}{2} \delta L_{\theta} \left. \frac{\delta F}{\delta F} \right|_{F=-g^2 F_D} + O(\theta^2). \quad (2.10)$$

At order $\theta$, loops play no role in the duality transformation so the quantum and semiclassical dual descriptions are equivalent. Plugging (2.10) into the action (2.5) gives,

$$S = -\frac{g^2}{4} \int \left( F_D \wedge *F_D + 2\text{tr}(\tilde{\theta} F_D^3) - \frac{1}{2}\text{tr}(\tilde{\theta} F_D) \text{tr}(F_D^2) \right) + O(\tilde{\theta}^2). \quad (2.11)$$

Note that we use $\tilde{\theta} = g^2(*\theta)$ as the new non-commutativity parameter. The factor of $g^2$ in $\tilde{\theta}$ is natural because of the following scaling argument: we can schematically expand $\tilde{F}^2$,

$$\tilde{F}^2 \sim F^2 \left( 1 + \sum_{n,l} \theta^{n+l} (\partial)^{2l} F^n \right), \quad (2.12)$$
on strictly dimensional grounds. This implies that iteratively, we can express $F$ in schematic form:

$$F \sim -g^2 F_D \left( 1 + \sum_{n,l} \theta^{n+l} (\partial)^{2l} (g^2 F_D)^n \right). \quad (2.13)$$

In terms of $\tilde{\theta}$, we see that

$$F \sim -g^2 F_D \left( 1 + \sum_{n,l} \tilde{\theta}^{n+l} (\partial)^{2l} \left( \frac{1}{g^2} \right)^l (F_D^n) \right). \quad (2.14)$$

The action now takes the form of a derivative expansion with higher derivatives of $F_D$ suppressed by powers of $g^{-1}$.

There are a number of observations at this point. Substituting even the lowest order expression,

$$F = -g^2 F_D + O(\theta), \quad (2.15)$$

into (2.5) results in an infinite number of terms involving higher powers of $\tilde{\theta}$. While terms beyond $O(\tilde{\theta})$ will receive additional corrections from the $O(\theta)$ corrections to (2.15), it seems quite clear – barring miraculous cancellations – that there is no upper bound on the power of $\tilde{\theta}$ that appears in the dual action. This suggests that it will be difficult to quantize the theory non-perturbatively in any conventional way. We also note that the dual action to leading order in $\tilde{\theta}$, expressed in dual non-commutative variables, takes the form

$$S = -\frac{g^2}{4} \int \widehat{F}_D \wedge \widehat{F}_D + O(\tilde{\theta}^2). \quad (2.16)$$

As is natural, we define $\widehat{F}_D$ with respect to a star product involving $\tilde{\theta}$. However, it is quite possible that the corrections to (2.16) of $O(\tilde{\theta}^2)$ are non-vanishing. It is not clear that the resulting dual action would then have a purely quadratic form.
