Abstract: We study the prospects of probing the anomalous \( tHq \) (\( q = u, c \)) couplings via SS2L or 3L signatures at the High Luminosity (HL-LHC) run of the 14 TeV CERN collider. We focus on signals of the \( tH \) associated production followed by the decay modes \( t \rightarrow b\ell^+\nu_\ell \) and \( H \rightarrow WW^* \), and \( t\bar{t} \) production followed by the decay modes \( t \rightarrow b\ell^+\nu_\ell \) and \( H \rightarrow WW^* \), where \( \ell = e, \mu \). Based on two types of \( H \rightarrow WW^* \) decay topologies, one assuming the semileptonic decay mode \( H \rightarrow WW^* \rightarrow \ell^+\nu_\ell jj \) and the other the fully leptonic decay mode \( H \rightarrow WW^* \rightarrow \ell^+\nu_\ell \ell^- \), we perform a full simulation for signals and backgrounds. It is shown that, at the future HL-LHC, the branching ratio \( Br(t \rightarrow uh) \) (\( Br(t \rightarrow ch) \)) can be probed to 1.17 \((1.56) \times 10^{-3} \) for the same-sign di-lepton channel, and to 7.1 \(\times 10^{-3} \) (1.39 \(\times 10^{-3} \)) for the 3L channel at 3\( \sigma \) sensitivity.

Keywords: anomalous top-higgs couplings, flavor changing neutral currents, LHC

PACS: 14.65.Ha DOI: 10.1088/1674-1137/43/1/013102

1 Introduction

Processes mediated by Flavor Changing Neutral Currents (FCNCs) are very rare in the Standard Model (SM) due to the Glashow-Iliopoulos-Maiani (GIM) mechanism [1]. However, because of the extended flavor structures existing in many New Physics (NP) models, the two-body FCNC decays \( t \rightarrow qX \) (\( q = u, c \) and \( X = g, Z/H \)) can be greatly enhanced: for example, in the Minimal Supersymmetric Standard Model (MSSM) with branching ratio \( Br(t \rightarrow cH) \sim 10^{-5} \) [2], in R-parity violating Supersymmetry (SUSY) with branching ratio \( Br(t \rightarrow cH) \sim 10^{-6} \) [3], in 2-Higgs-Doublet Models (2HDMs) with branching ratio \( Br(t \rightarrow cH) \sim 10^{-5} - 10^{-3} \) [4], in the little Higgs model with T-parity and the warped extra dimensions both with branching ratio \( Br(t \rightarrow cH) \sim 10^{-5} \) [5, 6] and so on. Thus any experimental signatures of such FCNC processes will serve as a clear signal for NP Beyond the SM (BSM) [7]. Up to now, top-Higgs FCNC interactions have been studied widely via anomalous top decays or anomalous production processes of single top quark [8–16].

Currently, the ATLAS and CMS collaborations have carried out searches [17–21] for \( tqH \) interactions with 7, 8 and 13 TeV data from the LHC. For example, using 13 TeV data, the ATLAS and the CMS experiments have studied the \( tqH \) FCNC processes in top quark pair events with \( H \rightarrow \gamma\gamma \) for ATLAS and \( H \rightarrow bb \) for CMS. The resulting observed (expected) limits for \( Br(t \rightarrow qH) \) at 95% Confidence Level (CL) have been found to be [19, 20]:

\[
\begin{align*}
Br(t \rightarrow Hu) & \leq \begin{cases} 
2.4 \times 10^{-3} \text{ ATLAS} \\
4.7 \times 10^{-3} \text{ CMS} 
\end{cases} \\
Br(t \rightarrow Hc) & \leq \begin{cases} 
2.2 \times 10^{-3} \text{ ATLAS} \\
4.7 \times 10^{-3} \text{ CMS} 
\end{cases}
\end{align*}
\]

(1)

Very recently, a search for production of top pairs in which one top quark decays via \( t \rightarrow qH \) is reported by the ATLAS Collaboration [21], with the subsequent Higgs boson decay to final states with at least one electron or muon. The upper limits on the branching fractions \( Br(t \rightarrow Hc) < 0.16\% \) and \( Br(t \rightarrow Hu) < 0.19\% \) at 95% CL are obtained (with expected limits of 0.15% in both cases). Apart from direct collider measurements, the upper limits of \( Br(t \rightarrow qH) \times 5 \times 10^{-3} \) and \( Br(t \rightarrow qH) \times 0.21\% \) can be obtained by bounding the \( tqH \) vertex from the observed \( D^0 - D\bar{0} \) mixing [22] and

The upcoming project of the HL-LHC is expected to reach 3 ab$^{-1}$. Preliminary sensitivity studies for the HL-LHC suggest the upper bound on $Br(t \rightarrow qH)$ to become about $1.5 \times 10^{-4}$ at 95% CL by the ATLAS Collaboration [24]. Further, many phenomenological studies within model-independent methods have been performed from different channels [25–33]. In this work, we study the prospects of probing the anomalous $tHq$ couplings by considering the processes of $tH$ associated production and $t\bar{t}$ production at the HL-LHC. We analyze two kinds of final states through leptonic top quark decays and study the sensitivity to the anomalous $tHq$ couplings. We summarize in Sec. III.

2 Numerical calculations and discussions

The general Lagrangian for FCNC top interactions with the Higgs boson can be written as

$$\mathcal{L} = \kappa_{tua} \bar{t}H u + \kappa_{tcH} \bar{t}cH + h.c.,$$

where the FCNC coupling parameters, $\kappa_{tua}$ and $\kappa_{tcH}$, are real and symmetric since we do not consider here the CP violating effects.

We perform systematic Monte Carlo (MC) simulations and study the sensitivity to the anomalous $tHq$ couplings through the associated $tH$ and $t\bar{t} \rightarrow tHq$ processes at HL-LHC. We first extract the relevant Feynman rules via the FeynRules package [35] and generate the events with MadGraph5-aMC@NLO [36]. The signal and backgrounds samples are simulated at parton level with the NN23LO1 Parton Distribution Function (PDF) set [37] and then passed through PYTHIA6.4 [38] and DELPHES [39] for parton shower and detector simulations, with the MLM matching scheme [40] adopted. Finally, event analysis is performed by using MadAnalysis5 [41].

2.1 Analysis of the SS2L channel

For the final states including the SS2L topology, the signals are generated through the following processes,

$$pp \rightarrow t(\rightarrow W^+b \rightarrow \ell^+qb)H(\rightarrow WW^* \rightarrow \ell^+\nu jj),$$

$$pp \rightarrow t(\rightarrow W^+b \rightarrow \ell^+qb)(\rightarrow Hq \rightarrow WW^*q \rightarrow \ell^+\nu jj q),$$

where $\ell = e, \mu$. The representative Feynman diagrams are shown in Fig. 1.

For this channel, the typical signal is exactly two same-sign leptons plus at least three jets, with at least one jet identified as $b$-jet, and missing transverse energy. The main backgrounds are $ttV$ ($V = W, Z$), $W^+W^+jj$ and $W^+Zjj$. The $t\bar{t}$ process, which has large cross section, may also contribute to background if a same-sign lepton pair comes from a $B$-hadron semi-leptonic decay in the $b$-jet. We do not consider other backgrounds from $ttH$, $tttt$, tri-boson events and $tHj$. They are neglected because the cross sections are all negligible after applying the selection cuts.

The cross sections of dominant backgrounds at Leading Order (LO) are adjusted to Next-to-LO (NLO) by means of $K$-factors, which are 1.04 for $W^+W^+jj$ jets [42], 1.24 for $ttW$ [43] and 1.39 for $tIZ$ [44]. The dominant $tt$ background is normalized to the NNLO QCD cross section of 953.6 pb [45]. For the $tH$ production cross section, the $K$-factor is taken as 1.5 at the 14 TeV LHC [12].

The decay chain $H \rightarrow WW^* \rightarrow \ell\nu jj$ may result in soft leptons and light jets, especially when they are coming from an off-shell $W$ boson. To analyze the signal sen-

![Fig. 1. Representative Feynman diagrams for the associated $tH$ process (left) and the FCNC decay of the top pair production process (right). Here $q = u, c$.](image)
is to be smaller than 250 GeV.

The effects of the cuts on the signal and background processes are illustrated in Table 1 for the SS2L channel, where the anomalous coupling parameters are taken as $\kappa_{t\ell b} = 0.1$ or $\kappa_{t\ell H} = 0.1$, while fixing the other to zero. From Table 1 we can see that, after all these cuts, the $t\bar{t}$ backgrounds for the SS2L channel with fake leptons from heavy-flavor jets or charge mis-identifications can be significant.

Obviously, the non-prompt backgrounds may also be significant, where non-prompt leptons are from heavy-flavor decays, mis-identified hadrons, muons from light-meson decays or electrons from un-identified conversions of photons into jets. Recently, the CMS collaboration searched for SS2L signatures [46] and found that the overall non-prompt backgrounds are about 1.5 times the $t\bar{t}W$ background after all cuts. These non-prompt backgrounds are not properly modeled in our MC simulations. Therefore, for simplicity, we add a non-prompt background that is 1.5 times $tW$ [46] after selection cuts to the overall background. Accounting for the theoretical and experimental systematic uncertainties on the background predictions would certainly improve the reliability of the results, yet they can only be neglected in our simulation.

### 2.2 Analysis of the 3L channel

Next, we consider the final states including 3L via the following processes:

$$pp \rightarrow t(\rightarrow W^+b \rightarrow \ell^+\nu b)h(\rightarrow WW^* \rightarrow \ell^+\nu\ell^-\bar{\nu}), \quad (5)$$
we choose the invariant mass $M$.

The dominant SM backgrounds are $t\bar{t}V$ ($V=W,Z$), $t\bar{t}H$, $WZ+$ jets and $t\bar{t}$. The multi-jet backgrounds (where jets can fake electrons) are not included since they are negligible in multi-lepton analyses [47].

The pre-selection cuts are taken as follows: there must exist exactly three isolated leptons ($\ell=e,\mu$) and exactly one $b$-tagged jet with $p_T(\ell_1) > 20$ GeV, $p_T(\ell_{2,3}) > 10$ GeV, $p_T(j,b) > 20$ GeV, $E_T > 100$ GeV and $|\eta_{\ell,j,b}| < 2.5$. These cuts can strongly reduce the $t\bar{t}$ background and its diboson components.

In Fig. 3, we show the invariant mass distribution of $M_{\ell_2\ell_3}$ and $M_{\ell_2}$ from the signal and backgrounds at the 14 TeV LHC. To remove contamination from hadron decay chains including $\ell^+\ell^-$ pairs and resonant Z bosons, we choose the invariant mass $M_{\ell_2\ell_3}$ cuts

$$12\text{GeV} < M(\ell_2\ell_3) < 55 \text{ GeV}.$$

Similarly, the invariant mass of the $b$-jet and the leading lepton, $M_{\ell_1}$, should be smaller than 140 GeV. The effects of the cuts on the signal and background processes are illustrated in Table 2 for the 3L channel. One can see that significant backgrounds also come from the top pair production process with fake leptons or charge mis-identifications.

Using the Poisson formula [48],

$$SS=\sqrt{2\mathcal{L}_{\text{int}}[(S+B)\ln(1+S/B)-S]}$$

we estimate the Signal Significance (SS) with fixed coupling parameters $\kappa_{tqH}$ and a given integrated luminosity $\mathcal{L}_{\text{int}}$. In Figs. 4 and 5, we plot the contours of $SS=3$ and $SS=5$, respectively, for two channels in the plane of $\mathcal{L}_{\text{int}}-\kappa_{tqH}$. It is clear that, for an integrated luminosity of 3000 fb$^{-1}$, the FCNC couplings $\kappa_{tqH}$ ($\kappa_{t\gamma}$) can be probed to 0.045 (0.052) and 0.035 (0.049) at 3$\sigma$ statistical sensitivity for the SS2L and 3L channels, respectively. After neglecting the masses of light quarks, the branching ratio of $t\rightarrow qH$ is approximately given by [13, 49]

$$Br(t\rightarrow qH) = \frac{\kappa_{tqH}^2}{\sqrt{2m_t^2G_F}} \frac{(1-x_q^2)^2}{(1-x_W^2)^2(1+2x_W^2)} \lambda_{\text{QCD}} \leq 0.58\kappa_{tqH}^2,$$\hspace{1cm} (7)

in terms of the Fermi constant $G_F$ and with $x_i = m_i/m_t$ ($i=W,\ h$). In our numerical calculation, the relevant SM input parameters are taken as [50]:

$$m_H=125 \text{ GeV}, \quad m_t=173.1 \text{ GeV}, \quad m_W=80.379 \text{ GeV}, \quad m_Z=91.1876 \text{ GeV}, \quad \alpha_s(m_Z)=0.1185, \quad G_F=1.166370\times10^{-5} \text{ GeV}^{-2}. \hspace{1cm} (8)$$

Using Eq. (7), the limits can be translated in terms of constraints on the branching fractions of rare top decays. The 3$\sigma$ CL upper limits on $Br(t\rightarrow qH)$ are $Br(t\rightarrow uH) = 1.17\times10^{-3}$ and $Br(t\rightarrow cH) = 1.56\times10^{-3}$ for the SS2L channel, and $Br(t\rightarrow uH) = 7.1\times10^{-4}$ and $Br(t\rightarrow cH) = 1.39\times10^{-4}$ for the 3L channel. The projected limits from different channels are summarized in Table 3. We can see from the table that our results are comparable with the sensitivity limits at the HL-LHC of $Br(t\rightarrow uH) < 0.036\%$ via the $H\rightarrow \gamma\gamma$ channel [29], $Br(t\rightarrow uH) < 0.05\%$ via the multi-lepton channel and $Br(t\rightarrow uH) < 0.02\%$ via the di-photon channel [51].

Table 1. The cut flow of the cross sections (in fb) for the signal and SM backgrounds for the SS2L channel. The coupling parameters are taken as $\kappa_{tqH}=0.1$ or $\kappa_{t\gamma}=0.1$, while fixing the other to zero.

3 Conclusions

The discovery of the 125 GeV Higgs boson opens the door to probe NP processes that involve Higgs boson associated production or decay. In this paper, we have investigated the signal of $t\bar{t}h$ associated production via FCNC $tqH$ couplings and $t\bar{t}$ production with $\bar{t}H$ for the SS2L channel, and $t\bar{t}$ production with $\bar{t}H$ for the 3L channel at the future HL-LHC.
