**ABSTRACT**

Introduction: Endophytic fungi are most commonly found in plants. They are present inside the plants and supporting plants to survive and produce many bioactive metabolites. Lovastatin is one of the secondary metabolites produced by the endophytic fungi. It is used in the treatment of high blood cholesterol and reduces the risk of cardiovascular diseases.

Objective: Screening and Production of Lovastatin Producing Endophytic Fungus from Phyllanthus reticulatus using Oyster Mushroom Extract.

Methods: In our study, we have isolated endophytic fungi from the leaves and stem of *phyllanthus reticulatus*. Biodiversity of the endophytic fungi was calculated. *Neurospora crassa* bioassay was performed to identify the best producer of lovastatin. Their Lovastatin production potential was investigated with two different mediums such as potato dextrose and the mushroom extract. After completion of the fermentation process, the broth was extracted by a simple distillation method and then analyzed for the presence of Lovastatin using UV-Visible spectrophotometer and HPLC.

Results: One of the positive and dominant endophytic fungi, *Curvularia* sp was isolated and chosen for this study. Its Lovastatin producing potential in PDA and mushroom extract medium was investigated and confirmed.

Conclusion: *Curvularia* sp was identified as a better Lovastatin producer when compared to other endophytic fungi isolated from *Phyllanthus reticulatus*. From the results of the UV and HPLC, the presence of lovastatin is confirmed.

Key Words: Endophytic fungi, Lovastatin, Bioassay, UV Spectrometry, High-performance liquid chromatography

**INTRODUCTION**

Endophytic fungi are the probable alternative sources for the development of novel biotechnological products like antibiotics, antifungal agents, immunosuppressants and anti-cancer compounds. Such microorganisms live in the plant’s internal tissue which supports the plant cells growth and metabolism. Fungal endophytes have been recognized as an excellent source for new compounds of enormous value in agriculture, industry and medicine.¹ ² They were the potential sources for the discovery of new and useful compounds or new platforms for the organic synthesis of such compounds for human benefit. Unlike organic synthetics, there is a clear need for endophytic sources of antimicrobials for their biological and chemical safety effects due to health and environmental problems.¹ ³ ⁴

Lovastatin is one of such secondary metabolites having huge medicinal properties and also naturally produced by certain higher fungi, such as *Pleurotus ostreatus* (oyster mushroom) and closely related *Pleurotus* sp.⁵ Chemical synthesis of Lovastatin strictly involves synthetic methods. It was the first statin drug which was patented⁶ and approved by the United States Food and Drug Administration (FDA) in 1987.⁶ ⁷ ⁹ The cost of production is too high for commercialization purposes and other commercially viable chemical processes only yield poor quality production and involve complicated production steps.¹⁰ ¹¹ Hence, biotechnology has opened a new avenue through simple biotechnological methods to produce high quality and cost-effective Lovastatin and it is summarized in Table 1.
**MATERIALS AND METHODOLOGY**

**Collection of Plant**
Healthy leaf, stem and root of *Phyllanthus reticulates* (Poir) was collected from the Theravada regions of Sathyamangalam Taluk in a sterile ziplock bag and processed within 24 hours at the Endophytic Fungal Metabolite Research Laboratory, Department of Biotechnology, Bannari Amman Institute of Technology. 20,21

**Isolation and Identification of endophytic fungi**
All the plant specimens were washed thoroughly with sterile water and endophytic fungi were isolated. 22,23 The surface sterile leaves, stem and petiole were dissected under sterilized conditions into small segments of 0.5 cm x 0.5 cm using a sterile scalpel and dried in blotting paper. They were placed equidistantly (10 segments per plate per specimen) on the freshly prepared Potato Dextrose Agar plates (PDA) amended with Chloramphenicol (50 μg/mL, Sigma Aldrich) and streptomycin sulphate (250 μg/mL, Sigma Aldrich) and incubated at 25°C±1°C.24,25

Identification of Endophytic fungi was carried out using microscopic and morphological characteristics. Isolated pure endophytic fungal cultures were stained using lactophenol cotton blue staining method and viewed under the microscope and were shown in Figures 2,3 and 4.

Among the group of endophytic fungi isolated from the plant, best fungal isolate (Table 2) was chosen based on the highest colonization frequency and zone of inhibition in a bioassay.

**Biostatistics for Species Diversity**

**Colonization Frequency Percentage (CF %)**
The density of colonization of single endophytes species was calculated and was equal to the number of colonized segments divided by the total number of segments observed x 100.

**Endophytic Infection Rate (EIR %)**
Endophytic Infection Rate was determined as the number of infected plant segments divided by the total number of plant segments screened x 100.26-30

**Screening by Neurospora crassa Bioassay**
This screening was based upon the use of biological responses as a detection system for biologically active substances. *Neurospora crassa* (MTCC 790) was sensitive to β hydroxyl acid of Lovastatin19 and hence, Lovastatin producing isolates create a zone of inhibition by suppressing the growth of this organism. Thus, using this principle, selected 10 endophytic fungal species were screened to identify their Lovastatin producing capabilities.26,27

**Batch fermentation**
Highly positive endophytic fungi obtained through screening was chosen for the further fermentation process. Hence, Fully grown mycelial culture (1cm x 1cm) of *Curvularia* sp from the agar plate was inoculated in 100 mL of two different media M1 and M2 (Table 3) at pH 6 in triplicates under sterile condition. All the flasks were incubated in a shaker incubator at 28°C and 180 rpm for 10 days.6,14,16

**Extraction and confirmation of Lovastatin production**
After 8 days of fermentation, the culture broth was separated by sterilized filter cloth. The culture filtrate was adjusted from pH 6 to pH 2 and was kept in a rotary shaker with an equal volume of ethyl acetate at 100 rpm for 2hrs at room temperature. After the extraction process, the broth was centrifuged at 1500 rpm for 20 min and filtered using Whatman filter paper No.1 to separate the biomass and filtrate. The filtrate was concentrated to 20 ml using rotary evaporator.23,24,25

The presence of Lovastatin in the fermentation broth was confirmed at the maximum absorbance by UV spectrophotometry at 238nm. Further, the sample was analyzed using HPLC with a C18 column as a stationary phase and acetonitrile and water (65:35 v/v) as mobile phase.2

**RESULTS**

**Biostatistics for Species Diversity**
The colonization frequency percentage of the endophytic fungal species were shown in table 4 and the endophytic fungal infection rate percentage of *Phyllanthus reticulatus* was shown in figure 5.

**Screening by Neurospora crassa Bioassay**
The zone of inhibition formed by the endophytic fungi against *Neurospora crassa* is shown in table 5. Among these, the *Curvularia* sp shows higher zones of inhibition up to 0.6cm when compared to the other organisms. Further studies were carried out using the *Curvularia* sp.
Batch fermentation
Fermentation of Curvularia was carried out in both PDB and mushroom extract medium. Every 2 days, biomass was collected, filtered using pre-weighed sterilized filter cloth and dried at 60 °C. Maximum OD of 0.826 in mushroom medium and 0.878 in PDB medium were observed at 238nm under UV spectrophotometer. The HPLC results of both the medium show that the peaks are closer enough to the standard lovastatin. It confirms the lovastatin production by Curvularia sp. The fermented biomass samples were shown in figure 6 and the HPLC results were shown in figure 7.

DISCUSSION
This study revealed that the endophytic infection rate was high in the stem segment of the selected plant and the Curvularia sp were more abundant in the leaves of the selected plant in terms of colonization frequency compared to other endophytic fungi isolated from the same plant. This may be due to the environmental suitability and interaction of Curvularia sp within the plant. This fungus has also shown a good inhibitory effect against Neurospora crassa which is one of the confirmatory tests for the production of lovastatin. Thus, this dominant fungus was chosen for the investigation of lovastatin production in a shaker flask level. The production of lovastatin by Curvularia sp in the mushroom extract and PDB medium was confirmed by UV and the HPLC. The R<sub>2</sub> value of lovastatin in the mushroom extract was 2.135 which is close to the hydroxyl form of standard lovastatin.<sup>30-32</sup>

CONCLUSION
The research findings of this study conclude that Curvularia sp may be used as one of the fungal isolates for the production of lovastatin in mushroom extract medium. This novel method of using these fungi for lovastatin was reported the first time and further studies may be done to enhance productivity.

ACKNOWLEDGEMENT
We wish to express sincere gratitude to Fungal Biodiversity and BioResources Research Laboratory at Bannari Amman Institute of Technology for providing facilities for the successful completion of research work.
