Department of Nephrology and Transplantation, Guy’s Hospital, Guy’s and St Thomas’ NHS Foundation Trust, London, UK

Introduction: Robotic surgery has been increasingly used in fashioning various surgical anastomoses. Our aim was to collect and analyze outcomes related to anastomoses performed using a robotic approach and compare them with those done using laparoscopic or open approaches through meta-analysis.

Methods: A systematic review was conducted for articles comparing robotic with laparoscopic and/or open operations (colectomy, low anterior resection, gastrectomy, Roux-en-Y gastric bypass (RYGB), pancreaticoduodenectomy, radical cystectomy, pyloplasty, radical prostatectomy, renal transplant) published up to June 2019 searching Medline, Scopus, Google Scholar, Clinical Trials and the Cochrane Central Register of Controlled Trials. Studies containing information about outcomes related to hand-sewn anastomoses were included for meta-analysis. Studies with stapled anastomoses or without relevant information about the anastomotic technique were excluded. We also excluded studies in which the anastomoses were performed extracorporeally in laparoscopic or robotic operations.

Results: We included 83 studies referring to the aforementioned operations (4 randomized controlled and 79 non-randomized, 10 prospective and 69 retrospective) apart from colectomy and low anterior resection. Anastomoses done using robotic instruments provided similar results to those done using laparoscopic or open approach in regards to anastomotic leak or stricture. However, there were lower rates of stenosis in robotic than in laparoscopic RYGB (p=0.01) and in robotic than in open radical prostatectomy (p<0.00001). Moreover, all anastomoses needed more time to be performed using the robotic rather than the open approach in renal transplant (p≤0.001).

Conclusion: Robotic anastomoses provide equal outcomes with laparoscopic and open ones in most operations, with a few notable exceptions.

Keywords: anastomosis, hand-sewn, leak, stenosis, stricture, robotic, laparoscopic, open

Introduction

The introduction of laparoscopic techniques is considered to be one of the most prominent changes in surgical practice in the last decade of the twentieth century.

Since the first laparoscopic cholecystectomy in 1987, minimally invasive approaches have become the mainstay of most abdominal surgical procedures. The benefits of minimally invasive surgery are well established and include reduced analgesic requirements, reduced wound-related complications, shorter length of hospital stay, and faster return to normal daily activities.

Laparoscopic surgery, however, has its technical limitations. As described by Ruurda et al, open procedures offer the surgeon unlimited flexibility in his/her body, arm, and
Hand-eye coordination is reduced number, gender and age, “Surgical System Dove” We systematically searched the following databases for articles published up to June 2019: Medline, Scopus, Google Scholar, Clinical Trials and Cochrane Central Register of Controlled Trials. We used the following search terms: “robotic”, “robotic-assisted”, “robot-assisted”, “colectomy”, “low anterior resection”, “anterior resection”, “rectal resection”, “gastrectomy”, “gastric bypass”, “pancreaticoduodenectomy”, “Whipple”, “cytectomy”, “ileal conduit”, “neobladder”, “pyeloplasty”, “prostatectomy”, “renal transplant”, “kidney transplant”, combined with the Boolean operators AND, OR.

Inclusion and Exclusion Criteria
We included only original articles written in English that compared robotic with laparoscopic and/or open procedures regarding the aforementioned types of operations, included data about anastomotic leak, anastomotic stricture and/or anastomotic time and the anastomoses were hand-sewn. We excluded reviews, case reports, congress abstracts, animal studies, original articles referring only to robotic operations without comparing them with either laparoscopic or open ones and original articles comparing robotic with laparoscopic and/or open operations, but without having data about anastomotic leak, anastomotic stricture and/or anastomotic time or without the anastomoses being hand-sewn or with the anastomoses performed extracorporeally in laparoscopic or robotic cases, and articles written in languages other than English.

Review and Analysis
We extracted data about patients’ number, gender and age, type of operation, approach (robotic, laparoscopic or open), anastomotic technique, anastomotic leak, anastomotic stricture and anastomotic time.

Statistical Analysis
Meta-analysis was performed using Review Manager Version 5.3. Dichotomous variables were assessed using risk ratio (RR), whereas continuous variables were assessed using mean difference. The random-effects model was chosen due to the heterogeneity among the included studies. Comparisons between dichotomous or continuous variables were made with the inverse variance method. Statistical heterogeneity was assessed with the Higgin’s $I^2$ statistic. Ninety-five percent confidence intervals (CI) were noted for all results. Results were considered statistically significant if p-value was less than 0.05.
Results

Search Results

The initial database search yielded 510 studies comparing robotic with laparoscopic and/or open operations in regards to the aforementioned types of procedures. Out of the initial 510 articles, 261 were excluded due to data unavailability about anastomotic leak, anastomotic stricture and/or anastomotic time. Out of the remaining 249 articles, 158 were excluded due to anastomotic techniques involving stapling devices or extracorporeally performed anastomoses in laparoscopic or robotic cases. Finally, another 8 studies were excluded due to overlapping cases, leaving 83 studies to be included in our analysis (4 randomized controlled and 79 non-randomized, 10 prospective and 69 retrospective). In particular, the distribution of included articles according to the exact type of operation was the following: colectomy: 0, low anterior resection: 0, gastrectomy: 4, Roux-en-Y gastric bypass (RYGB): 5, pancreaticoduodenectomy: 16, radical cystectomy: 1, pyeloplasty: 20, radical prostatectomy: 36, renal transplant: 1. Figure 1 shows the study flowchart.

Gastrectomy

Four studies referring to gastrectomy were taken into account for our analysis, including 689 adult patients in total (451 men, 238 women). All studies included both total and subtotal gastrectomies.5–9 There was one prospective randomized study conducted in China comparing robotic with laparoscopic gastrectomy. There were only two cases of anastomotic leak in the laparoscopic group (61 patients), while there were no cases of anastomotic leak in the robotic group (102 patients) (p=0.139).7

The other three articles compared robotic with open gastrectomy and these included two retrospective non-randomized studies, one from Spain6 and one from Italy,8 and one prospective randomized study from China.9 There was no significant difference in the rates of anastomotic leak between the two treatment groups [robotic: 5/231 (2.2%), open: 13/295 (4.4%), RR: 0.6, 95% CI: 0.19 to 1.94, p=0.4; I²: 7%, p=0.34]6,8,9 (Figure 2). Data about anastomotic stricture were available only in one study, in which there was only one case of anastomotic stenosis in the robotic group (20 patients), whereas there was no similar case in the open group (19 patients) (p=1).6

Roux-En-Y Gastric Bypass

Five studies referring to RYGB were considered for our analysis, which included 2155 adult patients in total (490 men, 1665 women).10–14 Out of these five studies, one was a prospective randomized trial conducted in the USA comparing robotic with laparoscopic RYGB,14 three were retrospective non-randomized done in the USA comparing again robotic with laparoscopic RYGB,10,11,13 and one was a retrospective non-randomized Swiss study with three treatment arms (robotic, laparoscopic, open).12

There was no statistically significant difference between robotic and laparoscopic RYGB in regards to anastomotic leak [robotic: 1/527 (0.2%), laparoscopic: 14/588 (2.4%), RR: 0.22, 95% CI: 0.04 to 1.38, p=0.11; I²: 7%, p=0.34]10–14 (Figure 3). However, there was an advantage of the robotic approach over the laparoscopic one in terms of anastomotic stricture [robotic: 0/381 (0%), laparoscopic: 24/542 (4.4%), RR: 0.07, 95% CI: 0.01 to 0.54, p=0.01; I²: 0%, p=0.72]10,12–14 (Figure 4). The only study that compared robotic with open procedures concluded that there is no statistically significant difference between robotic and open operations as far as anastomotic leak [robotic: 0/143 (0%), open: 10/524 (1.9%), p=0.21] or stricture [robotic: 0/143 (0%), open: 6/524 (1.1%), p=0.23] are concerned.12

Pancreaticoduodenectomy

Sixteen studies referring to pancreaticoduodenectomy were taken into account for our analysis, including 12,529 adult patients...
patients in total (6627 men, 5902 women). All included studies were retrospective non-randomized, apart from one prospective non-randomized study from China. Nine articles were from the USA, five from China, one from Italy and one from South Korea. Three articles compared robotic with laparoscopic operations, 12 articles compared robotic with open procedures, and one article compared all three options. No significant difference was noted between robotic and laparoscopic pancreaticoduodenectomy in regards to pancreatic leak [robotic: 93/451 (20.6%), laparoscopic: 107/560 (19.1%), RR: 1.08, 95% CI: 0.85 to 1.39, p=0.52; I²: 0%, p=0.72] (Figure 5) or bile leak [robotic: 7/45 (15.6%), laparoscopic: 7/45 (15.6%), RR: 0.54, 95% CI: 0.17 to 1.71, p=0.3; I²: 0%, p=0.94] (Figure 6). Similarly, no significant difference was detected between robotic and open pancreaticoduodenectomy in regards to pancreatic leak [robotic: 176/1086 (16.2%), open: 1679/10,526 (16%), RR: 0.93, 95% CI: 0.7 to 1.24, p=0.64] although there was significant heterogeneity among studies (I²: 74%, p=0.01) (Figure 7). Bile leak [robotic: 10/227 (4.4%), open: 18/491 (3.7%), RR: 1.27, 95% CI: 0.58 to 2.78, p=0.55; I²: 7%, p=0.37] or leak from gastrointestinal anastomoses [robotic: 2/82 (2.4%), open: 5/169 (3%), RR: 1, 95% CI: 0.22 to 4.57, p=1; I²: 0%, p=0.53] (Figure 8). There were no available data regarding anastomotic strictures.
Radical Cystectomy

Only one retrospective non-randomized study concerning radical cystectomy was included in our analysis, which was conducted in South Korea and compared robotic with open radical cystectomy.  

It included 139 adult patients (116 men, 23 women). Out of the 139 cases, a neobladder with hand-sewn urethrovessical anastomosis was formed in 41. There were 19 cases of open and 22 cases of robotic radical cystectomy. No postoperative anastomotic leak in the open group [0/19 (0%)], but there were three cases of postoperative anastomotic leak in the robotic group [3/22 (13.6%)]. However, this difference was not significant when we compared the two groups with Fisher’s exact test (p=0.235). There was no available information about anastomotic strictures.

Pyeloplasty

Twenty studies referring to pyeloplasty were considered for our analysis, which included 1158 patients in total.  

...
articles referred to paediatric patients, \(^{32,33,38,43,45–49,51}\) five articles referred to adult patients, \(^{34,35,37,42,44}\) and five articles referred to both paediatric and adult patients. \(^{36,39–41,50}\) Gender distribution was mentioned in 17 articles, \(^{32–34,36,37,40–51}\) which included 625 male and 432 female patients in total. All included studies were retrospective non-randomized, \(^{32–41,43–51}\) with the exception of one, which was prospective non-randomized. \(^{42}\) Eleven studies were from the USA, \(^{32,33,35,36,38,42,44,45,47,50,51}\) one from Italy, \(^{37}\) one from Switzerland, \(^{48}\) one from Israel, \(^{45}\) one from Turkey, \(^{34}\) two from India, \(^{39,41}\) two from China, \(^{40,49}\) and one from South Korea. \(^{46}\) Fourteen articles compared robotic with laparoscopic operations, \(^{35–45,48–50}\) four articles compared robotic with open procedures, \(^{32,33,47,51}\) and two articles compared all three options. \(^{34,46}\)

There was no significant difference between robotic and laparoscopic pyeloplasty concerning anastomotic leak \([\text{robotic: 1/100 (1%)}, \text{open: 7/278 (2.5%)}, \text{RR: 0.94, 95% CI: 0.18 to 4.85, }p=0.94; I^2: 10\%\), \(p=0.33\)]\(^{32–44,46,51}\) (Figure 10) or anastomotic stricture/failure \([\text{robotic: 3/133 (2.2%)}, \text{open: 8/311 (2.6%)}, \text{RR: 1, 95% CI: 0.32 to 3.09, }p=0.99; I^2: 0\%\), \(p=0.97\)]\(^{32–44,46,51}\) (Figure 11).

Radical Prostatectomy

Thirty-six studies referring to radical prostatectomy were taken into account for our analysis, including 40,313 adult male patients in total. \(^{52–87}\) Twenty-seven studies were retrospective non-randomized, \(^{52–57,60,62,63,65–70,72,73,75,76,78,79,81–84,86,87}\) eight studies were prospective non-randomized, \(^{58,59,61,64,71,74,77,85}\) and one study was prospective randomized. \(^{80}\) Twelve studies were from the USA, \(^{52,56,58,64,66,67,69,70,74,75,79,87}\) one from the UK, \(^{78}\) one from Germany, \(^{85}\) three from France, \(^{61,80,82}\) one from Belgium, \(^{53}\) three from Italy, \(^{62,71,81}\) one from Norway, \(^{68}\) two from Sweden, \(^{57,86}\) one from Switzerland, \(^{99}\) three from Australia, \(^{60,77,88}\) one from Canada, \(^{73}\) three from South Korea, \(^{65,83,84}\) one from Taiwan, \(^{76}\) one from Thailand, \(^{54}\) and one from Venezuela, \(^{72}\) while one study was multinational. \(^{53}\) Thirteen articles compared robotic with laparoscopic operations, \(^{53,54,63,65,67,68,71,76,79,81–84,86,87}\) 19 articles compared robotic with open procedures, \(^{52,55–59,61,62,66,69,72–75,77,82,85,86}\) and four articles compared all three options. \(^{60,70,78,83}\)

Total (95% CI) 100 278 100.0% 0.94 [0.18, 4.85]

Total events 1 7
Heterogeneity: Tau² = 0.23, Chi² = 2.23, df = 2 (P = 0.33), I² = 10%
Test for overall effect: Z = 0.08 (P = 0.94)
There was no significant difference between robotic and laparoscopic radical prostatectomy in terms of leak from the vesicourethral anastomosis [robotic: 152/4601 (3.3%), laparoscopic: 132/3913 (3.4%), RR: 0.92, 95% CI: 0.56 to 1.51, \( p=0.73 \)] [although there was significant heterogeneity among studies (\( I^2: 57\%, p=0.008 \))].

(Figure 14) or anastomotic stricture/contracture [robotic: 60/4907 (1.2%), laparoscopic: 72/3669 (2%), RR: 0.67, 95% CI: 0.42 to 1.07, \( p=0.09; I^2: 16\%, p=0.29 \)].

(\( I^2: 53,65,67,68,70,76,78-81,84,87 \))

(Figure 15) When we compared robotic with open radical prostatectomy, no significant difference was found in regards to leak from the vesicourethral anastomosis [robotic: 119/6097 (2%), open: 185/8323 (2.2%), RR: 0.76, 95% CI: 0.44 to 1.34, \( p=0.35 \)].

However, we have to mention that there was significant heterogeneity among the included studies for both comparisons between robotic and open procedures (anastomotic leak: \( I^2: 73\%, p<0.00001 \), anastomotic stricture/contracture: \( I^2: 45\%, p=0.03 \)).

Renal Transplant

Only one retrospective non-randomized study concerning renal transplant was included in our analysis, which was conducted in Turkey and compared robotic with open renal transplant. It included 80 adult patients (53 men, 27 women). All three anastomoses (arterial, venous, ureterovesical) were performed faster with the open than the robotic approach. In particular, the mean (SD) anastomotic times for arterial, venous and ureterovesical anastomoses were lower rates of anastomotic stricture/contracture in robotic approach [robotic: 180/9626 (1.9%), open: 1125/12,102 (9.3%), RR: 0.44, 95% CI: 0.32 to 0.62, \( p<0.00001 \)].
were 18.45 min (5.73), 20.92 min (6.57) and 21.30 min (4.73), respectively, in robotic cases, whereas they were 14.97 min (2.59), 16.02 min (2.30) and 14.95 min (1.56), respectively, in open cases. All differences were statistically significant (p ≤ 0.001). There was no available information about anastomotic leaks/bleeding or strictures.

**Discussion**

Since its introduction almost 20 years ago, robotic surgery has been successfully applied to key colorectal, gastric, pancreatic, urological and transplantation procedures where anastomoses form a critical part of the operation. Anastomoses are often time critical, in particular in transplantation where minimising warm ischaemia of the organ is critical to the graft function and outcome. Furthermore, anastomotic complications such as leak of urine or intestinal contents result in significant morbidity including the need for salvage surgery. The incidence of strictures or stenoses is also of importance in the functional outcome of an anastomosis and may necessitate
The integrity of the anastomosis, therefore, may represent a crucial factor when comparing the overall benefits of a robotic surgical approach to laparoscopic or open alternatives. In most comparisons, the robotic approach appears to provide similar results with the laparoscopic and open approaches in terms of anastomotic leak or stenosis. In particular, when we compared robotically performed anastomoses with laparoscopically performed anastomoses, no significant differences were found concerning leak or stricture after gastrectomy, leak after RYGB, pancreatic leak or bile leak after pancreaticoduodenectomy, leak or stricture/failure after pyeloplasty, and leak or stricture/contracture after radical prostatectomy. On the other hand, there were lower rates of anastomotic stricture after RYGB with the robotic technique. As far as the comparison of anastomoses performed with the robotic approach with those performed with the open approach, no significant differences were detected regarding leak or stricture after RYGB, pancreatic leak, bile leak or gastrointestinal leak after pancreaticoduodenectomy, leak or stricture/failure after pyeloplasty, and leak after radical cystectomy, and leak after radical prostatectomy. On the contrary, there were lower rates of anastomotic stricture/contracture after radical prostatectomy with the robotic technique.

Furthermore, it appears that all anastomoses (arterial, venous, ureterovesical) in renal transplant are performed more quickly via the open than the robotic approach. To conclude, robotically performed anastomoses provide similar results to those performed via laparoscopic or open approach, with the exception of RYGB, where the incidence of stenosis is less frequent in robotic than in laparoscopic operations, radical prostatectomy, where stenosis is less common in robotic than in open operations, and renal transplant, where the duration of anastomoses is longer in the robotic than the open approach.

It is important to note that the main focus of this analysis was a comparison of the anastomotic technique employed in these procedures, and the relevant anastomosis-related complications, which are deemed to confer significant morbidity, particularly in the early and mid-term post-operative period. This represents one of the limitations of this review, as it does not take into account oncological outcomes, incidence of nerve damage, incision size or incidence of incision-related complications, or ease of access, in particular for deep pelvic surgery. These are all factors that would undoubtedly contribute heavily when determining the overall benefit and/or superiority of robotic approaches as compared to open or laparoscopic approaches. For example, in robotic radical prostatectomy, superior vision and more intricate operating, facilitated by the robotic platform, has enabled improved nerve-sparing techniques resulting in superior functional outcomes, with no compromise in oncological outcomes. Our review also excluded procedures where a significant part of the operation is performed via a robotic approach, but not the relevant anastomosis – for example, in low rectal surgery for...
cancer. Current evidence suggests that the robotic approach for rectal cancer is of particular benefit in difficult cases such as patients with previous abdominal surgery and chemoradiation therapy. Lower conversion rates to open surgery have also been reported, as well as comparable, if not superior oncological outcomes than laparoscopic approaches, and significantly better autonomic functional outcomes. Furthermore, when comparing the overall advantages of robotic surgery to open or laparoscopic alternatives, cost-effectiveness is undoubtedly a key consideration. However, in many cases, the increased costs associated with a robotic system and its maintenance may well be offset by a shorter length of hospital stay and lower complication rates.

In conclusion, this review shows equivalent outcomes of robotically performed anastomoses with those performed via laparoscopic or open approach, apart from the few aforementioned exceptions. This means that the other benefits of robotic operations are not compromised by any deficit in anastomotic outcomes. This is with particular reference to abdominal operations where the anastomoses and its related complications are deemed to be a significant factor contributing to the overall morbidity and outcome. The choice of robotic over current gold-standard approaches for these operations, therefore, may lie with other demonstrable benefits such as superior vision, better access to the pelvis, and superior functional or oncological outcomes, as briefly discussed above.
