Background: The pregnane X receptor (PXR) not only plays an important role in cellular metabolism processes but also induces the resistance of hepatocellular carcinoma (HCC) cells to molecularly targeted drugs by mediating their metabolism and clearance by these cells. Endothelial PAS domain-containing protein 1 (EPAS-1) acts as a coactivator to regulate the transcription factor activity of PXR. In the present study, a microRNA that potentially targets EPAS-1, namely miR-3609, was identified using the miRDB tool.

Methods: The expression of miR-3609 and EPAS-1 was examined by qPCR. Lentiviral particles containing the full-length sequences of miR-3609 (pri-miR-3609) were prepared. The antitumor effect of antitumor agents was examined by the in vitro and in vivo assays.

Results: The expression of miR-3609 was negatively correlated with that of EPAS-1 in both HCC clinical specimens and paired non-tumor specimens, and the effect of miR-3609 on the expression of EPAS-1 was confirmed by Western blot experiments. Overexpression of miR-3609 decreased the expression of EPAS-1 and, in turn, repressed the activation of the PXR pathway. miR-3609 decreased the transcription factor activation of PXR, repressed its recruitment to its target gene promoter regions, and decreased the expression of its target genes CYP3A4 and P-GP. In addition, miR-3609 decelerated the metabolism and clearance of sorafenib in HCC cells and enhanced the antitumor effect of sorafenib in HCC cells.

Conclusion: Therefore, the results indicate that miR-3609 decreases the expression of EPAS-1 and enhances the sensitivity of HCC cells to sorafenib.

Keywords: microRNA-3609, molecular targeting agents, endothelial PAS domain-containing protein 1, pregnane X receptor, hepatocellular carcinoma

Introduction

The endothelial PAS domain-containing protein 1 (EPAS-1; also known as hypoxia-inducible transcription factors 2α, or HIF-2α) is a transcription factor that is expressed in several kinds of human cancers. In addition, EPAS-1 functions as a transcription regulator, modulating the activation of other transcription factors.1–3 Previously, EPAS-1 was considered to be a key regulator of hypoxia-related processes, mediating the transcription of hypoxia-related genes by binding to the hypoxia response elements (HRS) located in their promoters.4–6 Recently, increasing data have confirmed that EPAS-1 functions as a positive regulator of hepatocellular carcinoma (HCC) and promotes proliferation and metastasis by up-regulating the activation of several
signaling pathways, such as MAPK (mitogen-activated protein kinase) or TGFα (transformation growth factor α) pathways. Furthermore, EPAS-1 additionally acts as an important regulator of multidrug resistance (MDR) in HCC cells by enhancing the activation of PXR pathways, which, in turn, increases the expression of the MDR-related downstream genes of PXR, such as MDR-1 and CYP3A4.7–10 Therefore, EPAS-1 is a promising target for more effective antitumor therapies for HCC.

MicroRNAs are a class of non-coding RNAs, synthesized by RNA polymerase II, that have important physiological functions in cells.11–13 In mammalian cells, miRNAs recognize and bind to miRNA-binding sites at the 3’UTR (3’ untranslated region) of the mRNA (messenger RNA) of their target genes, in a sequence-specific manner. This results in the degradation of mRNA by Dicer, and plays a role in post-transcriptional gene-silencing.14–17 Therefore, screening for miRNAs that target oncogenes and silence their expression via miRNA activity is an effective antitumor strategy.18–21

Currently, most patients with HCC are diagnosed at the advanced stage of disease (advanced HCC) and therefore miss the opportunity to undergo radical treatment such as surgery.22,23 Moreover, patients with advanced HCC do not exhibit sufficient sensitivity to cytotoxic-chemotherapeutic drugs owing to multidrug resistance.24,25 Therefore, molecular-targeted drugs are still the main strategy for advanced HCC antitumor therapy.26,27 In the present study, a microRNA that potentially targets EPAS-1, namely miR-3609, was identified using an online tool (miRDB), and the expression levels of miR-3609 and EPAS-1 in clinical samples were examined. Lentiviral particles were prepared to overexpress miR-3609 in HCC cells. Overexpression of miR-3609 decreased the activation of transcription factors of the PXR pathway and reduced the rate of clearance of sorafenib in HCC cells by targeting EPAS-1. Moreover, miR-3609 enhanced the sensitivity of HCC cells to molecular targeting agents, including sorafenib.

Materials and Methods
Clinical Specimens and Patient-Derived Cells
The cDNA samples from clinical specimens and patient-derived cells from patients with advanced HCC were gifts from Dr. Fan Feng at the Research Center for Clinical and Translational Medicine, the fifth medical center of the Chinese People’s Liberation Army General Hospital (formerly the 302nd Hospital of Chinese PLA, Beijing, 100039, PR China).28–30 The collection of clinical specimens for the experiments in this study was performed in compliance with the Helsinki Declaration, and written informed consent was obtained from the participating patients. Furthermore, the study received approval by the ethics committee of the fifth medical center of the Chinese People’s Liberation Army General Hospital. For the clinical specimens, cDNA samples from a total of 52 HCC cases were used, as described in our previous study.28–30 In order to obtain patient-derived cells (PDCs), percutaneously punctured tissue samples from the liver were collected from patients who were newly admitted to the hospital, and single-cell suspensions were generated by tissue grinding. Patient-derived HCC cell lines (HCC PDC lines) were thus obtained.30 These HCC PDCs were preserved in liquid nitrogen.30

Cell Lines and Molecular Targeting Agents
MHCC97-H, a highly aggressive HCC cell line, was purchased from the Type Culture Collection of the Chinese Academy of Sciences (Shanghai City, People’s Republic of China), a culture collection center of the Chinese government. Cells were cultured in DMEM (Dulbecco’s Modified Eagle Medium) with 10% FBS (fetal bovine serum) at 37°C under 5% CO2. The molecular targeting agents, namely sorafenib (Cat. No. S7397), lenvatinib (Cat. No. S1164), regorafenib (Cat. No. S1178), apatinib (Cat. No. S5248), and anlotinib (Cat. No. S8726), were purchased from Selleck Corporation, Houston, Texas, USA. For the cell-based experiments, the powdered form of the molecular targeting agents was simply dissolved in dimethyl sulfoxide (DMSO) and diluted with DMEM with 0.5% FBS. For animal experiments, 20 mg of molecular targeting agent powders was carefully dissolved in a solution of 100 µL DMSO, 200 µL Tween 80, and 200 µL polyethylene glycol 400 (PEG 400). Then, the solutions (powders of agents dissolved in organic solvents) were slowly and carefully diluted with physiological saline to a total volume of 10 mL, resulting in a formulation of agents for oral administration/oral liquids, accompanied by ultrasonic processing or churning.31,32 Therefore, the concentration of agents in the formulation/oral liquids of agents for oral administration was ~2 mg/mL.
Quantitative Polymerase Chain Reaction (qPCR)

For reverse transcription and qPCR experiments, RNA samples were extracted from HCC cells using a PARISTM Kit (Thermo Fisher Scientific, Waltham, MA, USA). The RNA samples were reverse-transcribed with a Multiscribe™ Reverse Transcriptase (Thermo Fisher Scientific) agent. Next, qPCR was performed following the methods described by Ji et al and Liang et al. in order to examine the expression of genes in the cDNA samples from HCC clinical specimens. β-actin mRNA was used as a loading control, and the expression level of target genes relative to that of β-actin was measured. Primers used in the qPCR experiments were as follows: (1) MDR-1 forward sequence 5′-GCTGTCAGGAGCCAATGCTTCT-3′; reverse sequence 5′-TGTAATGACGACTCTGTTC-3′; (2) CYP3A4 forward sequence 5′-CCGAGTGGTCCCTCCTTTCA-3′; reverse sequence 5′-TGCTCGTGTTCTCATAGCGACG-3′; (3) β-actin forward sequence 5′-CACCATGGCAATGAGCGGTTC-3′; reverse sequence 5′-AGGTCTTTGCGGATGTCCACGT-3′. The correlation between the expression of miR-3609 and that of EPAS-1 was determined according to the qPCR results for tumor tissues and the corresponding non-tumor tissues (the paired para-cancerous tissues), using the two as the horizontal and vertical coordinates to obtain a scatter plot for further correlation analysis. For paired specimens (the tumor and the paired non-tumor/paired para-tumor tissues), the expression levels of EPAS-1 or miR-3609 in cancer-to-cancer specimens were determined according to the qPCR results for tumor tissues and the corresponding non-tumor tissues (the paired para-cancerous tissues), using the two as the horizontal and vertical coordinates to obtain a scatter plot for further correlation analysis. The methods has been added in the methods part (qPCR section).

Plasmids and Luciferase Assays

The luciferase reporters (XREM-Luc, PXRE-Luc, DR3-Luc, and ER6-Luc) used to examine the activation of PXR transcription factors were gifts from Dr. Fan Feng at the Research Center for Clinical and Translational Medicine, the fifth medical center of the Chinese People’s Liberation Army General Hospital; these reporters have been described in his previous publications. The HCC cells, which were transfected with plasmids, were seeded in 24-well cell culture plates (Corning Incorporated, Corning, NY, USA) using phenol red-free DMEM (Thermo Fisher Scientific) supplemented with 0.5% charcoal-stripped FBS (Hyclone, Logan, Utah, USA). Transfection experiments were performed with Lipofectamine 2000 transfection agent (Thermo Fisher Scientific Corporation, Waltham, MA, USA). Cells were treated with the indicated concentration of rifampicin (10 μmol/L, 3 μmol/L, 1 μmol/L, 0.3 μmol/L, 0.1 μmol/L, 0.03 μmol/L, and 0.01 μmol/L) for 24–48 h. Cells were transfected with plasmids (luciferase reporters) for 24h, and were then harvested to analyze the activation of luciferase and β-galactosidase following the instructions provided by the manufacturer (Promega Corporation, Madison, WI, USA). Results were shown as means ± SD from three independent experiments with similar results.

Antibodies and Western Blot

Antibodies against P-gp (P-glycoprotein), CYP3A4 (Cytochrome P450 3A4), EPAS-1, PXR, and β-actin, and polyclonal anti-rabbit/anti-mouse IgG antibodies conjugated with horseradish peroxidase (HRG), were purchased from Santa Cruz Biotec Ltd. (Dallas, TX, USA). HCC cells transfected with plasmids or treated with agents were harvested using radio-immunoprecipitation assay (RIPA) buffer, with the addition of protease inhibitor cocktails (Sigma-Aldrich Co., USA). Total protein samples were extracted from HCC cells and analyzed by sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE). Then, proteins on the SDS-PAGE gels were transferred onto polyvinylidene fluoride (PVDF) membranes (EMD Millipore, Billerica, MA, USA). Next, the membranes (blots) were blocked using 10% bovine serum albumin (BSA) diluted in a Tris saline buffer with Tween 20 (TBST). After blocking, the membranes were incubated for 2h at 37°C with rabbit primary antibody against P-gp (1:2000 dilution), CYP3A4 (1:1000 dilution), EPAS-1 (1:1000 dilution), PXR (1:2000 dilution), and β-actin (1:5000 dilution) diluted in TBST buffer containing 5% BSA. After incubating with the primary antibodies, the membranes were subsequently washed with TBST three times (5 min each time). After being washed, the membranes were incubated with the secondary antibodies (the horseradish peroxidase [HRP]-conjugated antibodies [1:5000 dilution]) diluted in TBST. After incubation with the secondary antibody, the membranes were again washed with TBST three times (5 min each time). Finally, the membranes were developed with enhanced chemiluminescence reagents (Thermo Fisher Scientific Corporation, Waltham, MA, USA) using X-ray films. The Western blot experiments were performed three times independently, with similar results.
Chromatin Immunoprecipitation
Rifampicin (Cat. No. S1764) was used as a PXR agonist. Rifampicin powder was dissolved in DMSO and diluted with phenol red-free DMEM. The solution, comprising 1% DMSO diluted with phenol red-free DMEM, was used as the solvent control. To examine the recruitment of PXR and EPAS-1 to the DNA-binding elements of PXR located in the promoter and enhancer regions of CYP3a4, a typical downstream gene of PXR, chromatin immunoprecipitation (ChIP) assays were performed according to protocols described in previous publications.\textsuperscript{28,29} HCC cells, which were transfected with plasmids or treated with agonist compounds (solvent control or PXR’s agonist) for 30 min to 1 h, were fixed by adding formaldehyde (4%) to the medium. After cross-linking, glycine was added to a final concentration of 125 mmol/L, and the HCC cells were harvested with a lysis buffer. The nuclear sub-fractions of HCC cells were pelleted by centrifugation and resuspended using a nuclear lysis buffer. Then, the nuclear lysates were sonicated to generate DNA fragments, about 0.5–1 kb in length, and ChIP experiments were performed using the antibodies against PXR and EPAS-1. The binding of PXR and EPAS-1 to the DNA fraction was examined by qPCR. The primers used in ChIP experiments included forward sequences of the cyp3a4 promoter: 5’-GGTTTCTCTGGAAGCCCTGTAG-3’; reverse sequence 5’-GTTTGCACCCGGACCCGTAC-3’; cyp3a4 enhancer forward sequence 5’-GGTTTCTCTGGAAGCCCTGTAG-3’; reverse sequence 5’-GTTTGCAACCCGGACCGTAC-3’; input genomic DNA forward 5’-GTGTTGTCTGTGCTCGGCGGTCTAC-3’; reverse 5’-GCAGGCTCAAGTCAACAGGAAATG-3’.

Cell Survival Assay
The inhibitory action of the molecular targeting agents on HCC cell survival was examined by MTT (3-[4,5-dimethyl-2-thiazolyl]-2,5-diphenyl-2-H-tetrazolium bromide, Thiazolyl Blue Tetrazolium Bromide) assay. The HCC cells were seeded into 96-well plates (8000 cells per well) and treated with the indicated concentrations of molecular targeting agents (10 μmol/L, 3 μmol/L, 1 μmol/L, 0.3 μmol/L, 0.1 μmol/L, 0.03 μmol/L and 0.01 μmol/L). Then, the drugs were diluted with DMEM (Thermo Fisher Scientific). Next, the MTT assay was performed, and the inhibition rates and IC\textsubscript{50} values were calculated following methods described in previous studies.\textsuperscript{36–38}

Pharmacokinetic Experiments
The metabolism and clearance of sorafenib in HCC cells were examined. For the cell-based experiments, cells were treated with 1 μmol/L sorafenib for 12 h. Then, the cells were harvested at the indicated time points, and the sorafenib was extracted from the cells with acetonitrile (ACN). The amount of sorafenib in the HCC cells was measured using liquid chromatography–mass spectrometry/mass spectrometry (LC-MS/MS) methods.\textsuperscript{39,40} For the animal experiments, a subcutaneous tumor model of HCC cells was established in nude mice. The animal experiments and methods were approved by the Institutional Animal Care and Use Committee, and all experiments were performed in accordance with the UK Animals (Scientific Procedures) Act, 1986, and associated guidelines. Nude mice (T-cell deficient mice), aged 4–6 weeks, were purchased from the Si-Bei-Fu Biotechnology Corporation (Beijing, People’s Republic of China). HCC cells were cultured and injected subcutaneously into the nude mice (1×10\textsuperscript{6} cells for each animal). After 3 to 4 weeks of growth, the sorafenib solution (2 mg/kg concentration) was injected into the subcutaneous tumors (50 μmol/L). Then, tumor tissues were harvested at indicated time points (0-time, 4h, 8h, 12h, 18h, 24h, 26h, 48h and 72h time-points for cell-based experiments; 0-time, 12h, 24h, 36h, 48h, 60h, 72h and 84h time-points for animal experiments). The amount of sorafenib in the tumors was measured using LC-MS/MS.\textsuperscript{40,41}

The Luciferase Experiments
The two sequences (1–300nt or the 661–960nt) of the 3’UTR of EPAS-1, containing the miR-3609 targeting sites or the mutated targeting sites, were cloned into the pGL-4.26 vectors. The two vectors were dubbed Luc-1 (Luc-1\textsuperscript{Mut}) and Luc-2 (Luc-2\textsuperscript{Mut}). HCC cells were transfected with control, miR-3609, and luciferase reporters, and used for luciferase reporter assays.\textsuperscript{35,40}

The Antitumor Effect of Sorafenib in vivo
The antitumor effects of sorafenib on HCC cells were examined in vivo using a subcutaneous tumor model. HCC cells were cultured and injected into nude mice (1×10\textsuperscript{6} cells for each animal). Three to 4 days after injection, the mice received the indicated concentration of molecular targeting agent (including sorafenib) treatment via oral administration, every 2 days. After 10 treatments (over 21 days), the nude mice and their subcutaneous tumor tissues were harvested.
The volumes and weights of tumor tissues were examined following previously described methods.\textsuperscript{42,43} The rates of suppression of tumor volumes and tumor weights by the agents were calculated as (control group’s tumor volume or tumor weight - experimental group’s tumor volume or tumor weight)/(control group’s tumor volume or tumor weight) × 100%.

Statistical Analysis
Analyses of statistical significance were performed using SPSS 9.0 (Statistical Product and Service Solutions Software, IBM Corporation, Armonk, NY, USA) statistical software by two-way ANOVA with Bonferroni correction; paired samples were tested using the paired-sample t-test. The IC\textsubscript{50} values of agents for HCC cells and the half-life time (t1/2) values of sorafenib retention in HCC cells were calculated using Origin software (Origin 6.1; OriginLab Corporation, Northampton, MA, USA).

Results
miR-3609 Potentially Targets EPAS-1 by Binding Its 3’UTR
First, the relationship between EPAS-1 and the prognosis of patients who received sorafenib was examined. As shown in Figure 1A and B, the expression of EPAS-1 was examined in the HCC clinical specimens, and patients were divided into two groups: EPAS-1-low and EPAS-1-high. The results showed that the EPAS-1-high group patients had poorer prognoses than those in the EPAS-1-low group (Figure 1A, B and Table 1). Next, using an online tool, miRDB, miR-
3609 was shown to potentially target EPAS-1 by binding its 3’UTR, and the potential binding of miR-3609 to EPAS-1 is shown in Figure 1C. To examine whether miR-3609 is associated with the prognosis of patients who received sorafenib treatment, the expression levels of miR-3609 and EPAS-1 were examined in the HCC clinical specimens. As shown in Figure 1C and D and Table 1, patients were divided into the following groups according to the median value of the expression level of miR-3609: an miR-3609-low group and miR-3609-high group. The miR-3609-low group patients had a poorer prognosis than the miR-3609-high group (Figure 1 and Table 2).

In addition, the relationship between EPAS-1 and miR-3609 in clinical specimens was examined. As shown in Figure 2A and B, the expression of EPAS-1 (Figure 2A) and miR-3609 (Figure 2B) in HCC clinical specimens was negatively correlated with their expression in paired non-tumor tissues. The expression of miR-3609 was also negatively associated with that of EPAS-1 in both HCC clinical specimens (Figure 2C) and the paired non-tumor tissues (Figure 2D). Lentiviral particles containing the full length of miR-3609 were then prepared in order to overexpress miR-3609 in MHCC97-H, a highly aggressive HCC cell line that expresses the highest level of EPAS-1 compared with other hepatic cell lines (Figure 2E). As shown in Figure 2F, overexpression of miR-3609 repressed the expression of EPAS-1. Transfection with an inhibitor of miR-6077 and EPAS-1 with mutated miR-3609-targeting sites (dubbed EPAS-1Mut) almost fully abrogated the repressing effect of miR-3609 on EPAS-1 expression (Figure 2F and F). Similar results were obtained from the luciferase assay, in that miR-3609 was found to repress the activation of the luciferase reporter containing the 3’UTR region of EPAS-1 with the miR-3609 targeting site but not the mutated miR-3609 targeting site (Supplemental Figure 1). Therefore, these findings show that miR-3609 targets the 3’ UTR of EPAS-1.

### miR-3609 Inhibits the Activation of PXR Pathway by Targeting EPAS-1

Based on previous evidence that EPAS-1 functions as a coactivator of PXR, the effect of miR-3609-mediated downregulation of EPAS-1 expression on the transcription factor activation of PXR was examined. As shown in Table 3, rifampicin, a typical agonist of PXR, induced transcription factor activation in a dose-dependent manner. The overexpression of miR-3609 repressed the agonistic effect of rifampicin on the activation of PXR, and the EC\textsubscript{50} (half-effective concentration/concentration of the 50% effective activation) values were increased (Table 3). Transfection with an inhibitor of miR-3609 or EPAS-1 with mutated miR-3609-targeting sites (dubbed EPAS-1Mut) almost fully blocked the repression of PXR activation by miR-3609 (Table 3).

Next, the effect of miR-3609 on the expression of the MDR-related target genes of PXR was examined. As shown in Figure 3, rifampicin induced the expression of P-GP and CYP3A4. Overexpression of miR-3609 decreased the expression of f P-GP and CYP3A4 induced by rifampicin (Figure 3). Transfection with an inhibitor of miR-3609 or EPAS-1 with mutated miR-3609-targeting sites (dubbed EPAS-1Mut) almost fully blocked the repressing effect of miR-3609 (Figure 3). The EC\textsubscript{50} values for the effect of rifampicin on the mRNA level in MHCC97-H cells and the five HCC PDC lines are shown in Supplemental Table 1.

Because PXR is a transcription factor/nuclear receptor whose activity relies on its nuclear accumulation and recruitment to the promoters of its target genes, cellular sub-fraction and ChIP experiments were performed. As shown in Figure 4, rifampicin (5 µmol/L concentration) induced the nuclear accumulation of PXR and its recruitment to the promoter/enhancer regions of cyp3a4. Overexpression of miR-3609 decreased the nuclear accumulation of PXR in the nuclear fraction and attenuated the

| Table 1 EPAS-1 Expression and Clinical Outcome of Patients Received Sorafenib Treatment |

rifampicin-induced recruitment of PXR to cyp3a4’s promoter/enhancer regions (Figures 4 and 5). Transfection with an inhibitor of miR-3609 and EPAS-1 with mutated miR-3609-targeting sites (dubbed EPAS-1\textsuperscript{Mut}) almost fully blocked the repressing effect of miR-3609 (Figures 4 and 5).

miR-3609 Reduces the Rate of Metabolism and Clearance of Sorafenib in HCC Cells

The MDR-related target genes of PXR generally encode drug-metabolizing enzymes; therefore, the metabolism and clearance of sorafenib in HCC cells warrant attention. The clearance of sorafenib in HCC cells was examined using

LC-MS/MS methods. As shown in Figure 6, sorafenib was gradually metabolized and cleared in HCC cells. Overexpression of miR-3069 reduced the rate of metabolism and clearance of sorafenib in cultured HCC cells (Figure 6), and the half-life time ($t_{1/2}$) of sorafenib in HCC cells was correspondingly prolonged (Table 4). The results are shown as a drug-retention curve for sorafenib in MHCC97-H cells (Figure 6) and the half-life time ($t_{1/2}$) of sorafenib in MHCC97-H and five HCC PDC lines (Table 4). Transfection of EPAS-1 with mutated miR-3609-targeting sites (dubbed EPAS-1$^{\text{Mut}}$) almost fully blocked the effect of miR-3609. Furthermore, similar subcutaneous tumor formation data were obtained (Figure 6 and Table 4). Therefore, miR-3609 was found to reduce the rate of metabolism and clearance of sorafenib in HCC cells.

miR-3609 Enhances the Antitumor Effect of Sorafenib on HCC Cells

To examine the antitumor effect of sorafenib in HCC cells, MTT assays were conducted. As shown in Supplemental Table 2, sorafenib inhibited the survival of MHCC97-H cells in a dose-dependent manner. Overexpression of miR-3609 enhanced the antitumor effect of sorafenib on MHCC97-H cells, and the IC$_{50}$ values of sorafenib on MHCC97-H cells were decreased. Transfection with the miR-3609 inhibitor and EPAS-1 with mutated miR-3609-targeting sites (dubbed EPAS-1$^{\text{Mut}}$) almost fully blocked the effect of miR-3609 (Supplemental Table 2). Overexpression of miR-3609 also enhanced the antitumor effect of other molecular targeting agents on MHCC97-H cells. Similar results were obtained in the five HCC PDC lines (Supplemental Table 2).

To further examine the in vivo effect of miR-3609, the nude mice HCC subcutaneous models were used. As shown in Figure 7, sorafenib inhibited the subcutaneous growth of MHCC97-H cells in a dose-dependent manner, and overexpression of miR-3609 enhanced the antitumor effect of sorafenib in MHCC97-H cells. The IC$_{50}$ values for this effect of sorafenib on MHCC97-H cells decreased (Table 5). Transfection with the inhibitor of miR-3609 and EPAS-1 with mutated miR-3609-targeting sites (dubbed EPAS-1$^{\text{Mut}}$) almost fully blocked the effect of miR-3609.

![Figure 3](image3.png)

**Figure 3** miR-3609 repressed the expression of drug resistance–related genes downstream of PXR. MHCC97-H cells, which were transfected with control, miR-3609, miR-3609 + EPAS-1$^{\text{Mut}}$, or miR-3609 + inhibitor, were treated with solvent control or rifampicin. Then, cells were harvested for Western blot analysis. The expression levels of EPAS-1, CYP3A4, P-gp, PXR, and β-Actin were examined using antibodies against these proteins. β-Actin was used as the loading control.

![Figure 4](image4.png)

**Figure 4** miR-3609 inhibited the recruitment of PXR to the promoter region (+4 ~ −354, PXRE region) of its target gene cyp3a4$′$. MHCC97-H cells, which were transfected with control, miR-3609, miR-3609 + EPAS-1$^{\text{Mut}}$, or miR-3609 + inhibitor, were treated with solvent control or rifampicin. Then, cells were harvested for chromatin immunoprecipitation (ChIP) analysis. The recruitment of PXR to its downstream gene cyp3a4$′$ promoter region (+4 ~ −354, PXRE region) is shown in DNA electrophoresis images (A) or assessed by quantitative analysis of the DNA electrophoresis images (B). *P < 0.05 versus the recruitment of EPAS-1 in the miR-3609 group with control, miR-3609 + EPAS-1$^{\text{Mut}}$, or miR-3609 + inhibitor groups; #P < 0.05 versus the recruitment of PXR in miR-3609 group, with control, miR-3609 + EPAS-1$^{\text{Mut}}$, or miR-3609 + inhibitor groups.
Overexpression of miR-3609 also enhanced the antitumor effect of other molecular targeting agents on the subcutaneous growth of MHCC97-H cells. Similar results were obtained in the five HCC PDC lines (Table 5).

To further examine the effect of miR-3609, other molecular targeting agents were used. As shown in Supplemental Table 3, miR-3609 enhanced the sensitivity of MHCC97-H cells to the molecular targeting agents regorafenib, lenvatinib, apatinib, and anlotinib, and the IC\textsubscript{50} of these agents were decreased. Transfection of an inhibitor of miR-3609 or EPAS-1\textsuperscript{Mut} decreased the effect of miR-3609. Therefore, overexpression of miR-3609 decreased the activation of PXR and enhanced the sensitivity of HCC cells to molecular targeting agents.

**Discussion**

HCC remains one of the most frequent malignancies in China, which has a high hepatitis rate, including infections due to hepatitis B virus [HBV] and hepatitis C virus [HCV]. A large proportion of HCC patients are already in the advanced stage of the disease (advanced HCC) when initially diagnosed, and have a poor prognosis because of multidrug resistance, which makes these patients insensitive to the traditional cytotoxic-chemotherapeutic agents. Currently, molecular targeting therapies, such as sorafenib and lenvatinib (first-line agents) and regorafenib (a second-line agent) are the only antitumor drugs available for advanced HCC.

Although molecular targeting agents are promising therapeutic options, they have several limitations: patients show individual differences in sensitivity to molecular targeting agents, and are prone to developing drug resistance during treatment. It has been reported that several mechanisms may contribute to drug resistance in advanced HCC treatment; these include signaling pathways, including Notch pathways, EMT, and cancer stem cells related signaling pathway. The present results show that EPAS-1 may be a promising target for enhancing the antitumor effect of molecular targeting agents on HCC cells (Figure 8). Overexpression of miR-3609, a microRNA that potentially targets EPAS-1, enhanced the antitumor effect of molecular targeting agents on HCC cells by decreasing PXR activation. These results not only expand our understanding of EPAS-1, but also contribute to the development of safer and more effective HCC molecular-targeted therapeutic strategies.

It has been reported that the metabolism-dependent elimination of sorafenib (ie, the metabolism and clearance of sorafenib) mediated by the PXR signaling pathway plays an important role in sorafenib-resistance in HCC cells.

As a member of the nuclear receptor protein family, EPAS-1 (also known as HIF-2α) is a key regulator of hypoxia-responsive genes and is involved in the response to hypoxia and other stimuli. Previous studies have shown that EPAS-1 is upregulated in various types of cancer, including HCC, and its overexpression is associated with poor prognosis. However, the role of EPAS-1 in the antitumor effect of molecular targeting agents on HCC cells has not been well studied. In this study, we found that overexpression of miR-3609, a microRNA that potentially targets EPAS-1, decreased the activation of PXR and enhanced the sensitivity of HCC cells to molecular targeting agents. These results suggest that EPAS-1 may be a promising target for enhancing the antitumor effect of molecular targeting agents on HCC cells.
family, PXR can function as a transcription factor to mediate the transcription of its target genes, which encode metabolizing and detoxifying enzymes such as P-GP and CYP3A4. These enzymes not only participate in the metabolism and detoxification of exogenous toxicants, but also induce drug resistance via metabolism-dependent
elimination of the drug during treatment. The activation of PXR is regulated by both ligands and co-regulators. Zhao et al (2016) reported that EPAS-1 interacts with PXR and functions as a PXR coactivator.

In the present study, overexpression of miR-3609 decreased the activation of the PXR pathway by repressing the expression of EPAS-1, and enhanced the antitumor effect of molecular targeting agents. Furthermore, overexpression of miR-3609 not only decreased the expression of MDR-related genes but also reduced the rate of metabolism-dependent elimination of sorafenib in HCC cells. This study not only examines MDR-related protein expression but also directly investigates the metabolism and clearance of sorafenib in HCC cells. The results enable a more comprehensive study of sorafenib tolerance.

Sorafenib has been widely used in clinical practice, and more information on its drug characteristics is available; in comparison, regorafenib and lenvatinib have been in use for a shorter period, and therefore less corresponding information exists for these drugs. This study examined

Figure 7 miR-3609 enhanced the in vivo antitumor effects of sorafenib in nude mice. MHCC97-H cells transfected with miR-3609 were injected subcutaneously into nude mice to form tumor tissues. Mice received sorafenib treatment via oral administration. After treatment, the mice were harvested, and the tumor tissues collected. Images of tumor tissues are shown (A) and the inhibitory rates calculated by tumor volumes (B) or tumor weights (C) are indicated; *P < 0.05.
the metabolism and scavenging effects of sorafenib in HCC cells. LC-MS/MS detection methods for the analysis of other molecularly targeted drugs will be established in future for similar studies.

Recently, the alteration of micro-environments of tumor tissues mediated by increased metabolism, termed “the Warburg effect”, which is characterized by elevated glucose uptake, has been considered a potential mechanism underlying drug resistance. The aberrant metabolism of human cancer cells not only involves markedly high levels of glycolysis and glucose absorption, even at normal oxygen concentrations, but also induces the alteration of the micro-environment, metastasis, or drug resistance of cells because of the accumulation of lactate. Inhibition of the Warburg effect has been considered as a potential antitumor treatment strategy. For example, Yin et al (2019) reported that repressing the activation of SREBP-1 enhanced the sensitivity of HCC cells to sorafenib by suppressing the Warburg effect in HCC cells. Ma et al (2019) showed that miR-6077 enhanced the sensitivity of NSCLC cells to lenvatinib by repressing the expression of GLUT1. Furthermore, other strategies to inhibit the Warburg effect in tumor cells are available; these include: (1) construction of lentivirus vectors of miRNAs to inhibit the expression and activation of metabolism-related pathways, including hypoxia-inducible factor and c-MYC; and (2) developing antibodies and small molecular inhibitors of metabolism-related pathways.

EPAS-1 is also referred to as hypoxia-inducible transcription factor 2α and plays an important role in several intracellular processes such as vascular remodeling, fibro-genesis and hypoxia-inducible process. The function of EPAS-1 is related, but different from, that of HIF1α (hypoxia-inducible transcription factors 1α). The results of the present study and those of Zhao et al (2016) show that EPAS-1 can up-regulate PXR activity as a coactivator. These results not only link the hypoxia-responsive signaling pathways to cellular metabolism-related mechanisms but also provide new experimental data for HCC treatment. Further, this study provides novel insights into the roles of miRs in HCC and other cancers.

![Figure 8](https://www.dovepress.com/figures-the-proposed-model-of-the-present-study-a-epas-1-functions-as-a-coactivator-of-pxr-and-enhances-the-activation-of-pxr-to-mEDIATE-the-expression-of-the-downstream-drug-related-genes-of-pxr-resulting-in-accelerated-metabolism-or-clearance-of-sorafenib-in-hcc-cells-b-miR-3609-inhibits-the-expression-of-epas-1-resulting-in-the-down-regulation-of-the-pxr-pathway-to-reduce-the-rate-of-metabolism-or-clearance-of-sorafenib-in-hcc-cells-the-overexpression-of-miR-3609-enhances-the-sensitivity-of-HCC-cells-to-sorafenib.)

Figure 8 The proposed model of the present study. (A) EPAS-1 functions as a co-activator of PXR and enhances the activation of PXR to mediate the expression of the downstream drug-related genes of PXR, resulting in accelerated metabolism or clearance of sorafenib in HCC cells. (B) miR-3609 inhibits the expression of EPAS-1, resulting in the down-regulation of the PXR pathway to reduce the rate of metabolism or clearance of sorafenib in HCC cells. The overexpression of miR-3609 enhances the sensitivity of HCC cells to sorafenib.
Conclusion
Overexpression of miR-3609 reduces the rate of clearance of sorafenib in HCC cells by targeting EPAS-1 and reducing the activation of PXR pathways. Therefore, EPAS-1 represents a promising molecular candidate for gene targeting therapy to overcome drug resistance during HCC treatment.
