BAND STRUCTURE

The full 3D band structure for the chiral woodpile structure discussed in the main text is plotted in Fig. S1 (a). The two bands that make up the Weyl point are well-separated in frequency along the $Y - \Gamma - X$ directions but are very close in frequency along $\Gamma - Z$. We perform convergence tests in MPB that confirm that the degeneracy only occurs at $\Gamma$. This structure also has a charge $-2$ Weyl point at $R$ between bands 3 and 4 which lies below the light line of air. Fig. S1 (b) shows the band structure for the same structure but with $\varepsilon_{\text{rods}} = 12$. The charge $\pm 2$ Weyl points remain at $\Gamma$ and $R$ points of the Brillouin zone, protected by screw symmetry.

CALCULATION OF BERRY PHASE

As discussed in the main text, we numerically calculate the topological charge (Chern number) associated with the Weyl points at $\Gamma$ and $R$ of the chiral woodpile PhC. Here we describe that algorithm, following Ref. [1]. Consider a closed contour $C$ in momentum ($\mathbf{k}$) space discretized into $N$ points ($\mathbf{k}_1, ..., \mathbf{k}_{N-1}$) such that $\mathbf{k}_N = \mathbf{k}_1$. The total

* These authors contributed equally to this work
phase acquired by a state undergoing adiabatic transport along this loop is numerically calculated by

$$\theta_B(C) = -\operatorname{Im} \ln \left( \prod_{i=1}^{N} \frac{\langle \psi(k_i) | \psi(k_{i+1}) \rangle}{\langle \psi(k_{i+1}) | \psi(k_i) \rangle} \right)$$  \hspace{1cm} (S1)

$\theta_B(C)$ is a manifestly gauge-invariant quantity and is called the Berry phase. In our case, the states in a 3D PhC are magnetic field eigenmodes of the Maxwell operator [2] that satisfy

$$\nabla \times \left( \frac{1}{\varepsilon(r)} \nabla \times \mathbf{H}(r) \right) = \left( \frac{\omega}{c} \right)^2 \mathbf{H}(r)$$  \hspace{1cm} (S2)

and the inner product between two such eigenmodes is defined as

$$\langle \psi_1 | \psi_2 \rangle = \int \mathbf{H}_1^*(r) \cdot \mathbf{H}_2(r) d^3r$$  \hspace{1cm} (S3)

This phase is calculated on circular contours that lie on constant $k_z$ planes as shown in Fig. S2 (b). The topological charge of the Weyl point is the number of times the Berry phase winds as a function of $k_z$.

![Fig. S2](image)

**Fig. S2.** (a) Closed contours in k-space discretized into $N$ points. (b) The Berry phase is calculated on circular contours that enclose the Weyl point. Each contour lies on a constant $k_z$ plane. (c), (d) Berry phase vs. $k_z$ plots for charge +2 and charge −2 Weyl points at $\Gamma$ and $R$ respectively.

To show that the Weyl points are indeed symmetry protected and continue to exist even at low contrast, we start with a high contrast version of our PhC and plot the band structure and Berry phase as the contrast is smoothly lowered. An animated version of these plots can be found in the supplementary material.

### COUPLING COEFFICIENTS BETWEEN INCIDENT PLANE WAVES AND PHC BLOCH MODES

To understand the relationship between the observed spectral features and the bulk bands, we calculate coefficients that measure the polarization of Bloch modes. For this, we consider plane waves with s- and p- polarizations incident along the $\Gamma - X$ direction on the PhC-air interface and define the polarization coupling coefficients $C_s$ and $C_p$ and mode coupling index $\kappa$ [3–6]

$$\eta_{p,k,n} = \frac{\iiint \mathbf{y} \cdot \mathbf{H}_{k,n}(x,y,z) dx dy dz}{V \iiint |\mathbf{H}_{k,n}(x,y,z)|^2 dx dy dz} \hspace{1cm} (1)$$

$$\eta_{s,k,n} = \frac{\iiint (\cos \theta \hat{x} - \sin \theta \hat{z}) \cdot \mathbf{H}_{k,n}(x,y,z) dx dy dz}{V \iiint |\mathbf{H}_{k,n}(x,y,z)|^2 dx dy dz} \hspace{1cm} (2)$$

$$\kappa = \eta_{s,k,n} + \eta_{p,k,n}; \hspace{1cm} C_s/p = \frac{\eta_{s/p,k,n}}{\kappa} \hspace{1cm} (3)$$

where $\mathbf{H}_{k,n}(x,y,z)$ is the magnetic field eigenmode of the PhC with momentum $\mathbf{k}$ and band index $n$, $\theta$ is the angle of incidence along $\Gamma - X$ and all integrals are calculated over a unit cell with volume $V$. $\kappa$ goes from 0 to 1.
and measures the strength of coupling to a plane wave of any arbitrary polarization while \(C_s\) and \(C_p\) measure the overlap between s- and p-polarized plane waves and the Bloch modes. Large reflection for a certain range of angles and frequencies in the absence of band gaps can then be thought of as either a polarization mismatch between the incident wave and the Bloch mode, indicated by small \(C_{s/p}\), and/or inefficient mode in-coupling, indicated by small \(\kappa\).

In Fig. S3, we analyze a slice of the reflection spectrum that corresponds to Bloch modes with momenta \(\mathbf{k} = (0.1, 0, k_z)\) \((2\pi/a)\). As previously stated, the band structure weighted by the coupling coefficients shows that there are wavelength ranges where the states are nearly completely s- or p- polarized and/or have small mode coupling index. We particularly point out the wavelength ranges \(\sim 4.65 - 4.8 \mu m\) in Fig. S3 (b) and \(\sim 5.0 - 5.15 \mu m\) in Fig. S3 (d) (highlighted in blue) which coincide with the sharp increases in reflection. Moreover, the boundary separating the reflecting and transmissive region coincides with band 4 at \(k_z = 0\) in s-polarization and band 5 at \(k_z = 0\) in p-polarization plots, which are the Weyl bulk bands of interest. Thus the signatures of both bands and the Weyl point are present in simulations and measurements done with 45° polarization.

**FIG. S3.** (a), (c) Angle-resolved RCWA simulation of reflection spectra for p and s polarizations respectively as shown in Fig. 3 of the main text. (b), (d) Reflection spectrum along the cut shown by the dashed line in (a) and (c) and the band structure showing bands 3 to 12 for \(\mathbf{k} = (0.1, 0, 0)\) to \((0.1, 0, 0.5)\) \((2\pi/a)\). The color of the circular dots indicates the value of \(C_{s/p}\) for the corresponding Bloch modes and their size is proportional to the value of \(\kappa\).
ADDITIONAL MEASUREMENTS

To provide additional evidence for the robust symmetry protection of the Weyl point, we fabricate and measure another sample with significantly different parameters: rod width of 300 nm and lattice constant of 2.1 µm. Fig S4 shows a SEM image of the sample, along with its transmission spectra. In this case, the transmission measurement was performed using the Hyperion 3000 microscope attached to the FTIR with the in-coupling Cassegrain objective covered except for a small pinhole of 2 mm diameter. This resulted in better k-space resolution for the measurement. We see in Fig. S4 that the charge +2 Weyl point continues to exist, even for these different parameters, and now resides at a wavelength of 2.4 µm.
