1. Introduction

Investigation of the $B$ meson decays into tensor mesons is useful in several aspects such as CP asymmetries, isospin symmetries, and the longitudinal and transverse polarization fractions. A large isospin violation has already been experimentally detected in $B \to \omega K^*_0(1430)$ mode [1]. Also, the decay mode $B \to \phi K^*_0(1430)$ is mainly dominated by the longitudinal polarization [2, 3], in contrast with $B \to \phi K^*$, where the transverse polarization is comparable with the longitudinal one [4]. Therefore, nonleptonic and semileptonic decays of $B$ meson can play an important role in the study of the particle physics.

In the flavor $SU(3)$ symmetry, the light $p$-wave tensor mesons with $J^P = 2^+$ containing isovector mesons $a_2(1320)$, isodoublet states $K_2^*(1430)$, and two isosinglet mesons $f_2(1270)$ and $f_2^*(1525)$ are building the ground state nonet which has been experimentally established [5, 6]. The quark content $q\overline{q}$ for the isovector and isodoublet tensor resonances is obvious. The isoscalar tensor states, $f_2(1270)$ and $f_2^*(1525)$, have mixing wave functions where mixing angle should be small [7, 8]. Therefore, $f_2(1270)$ is primarily a $(u\bar{u} + d\bar{d})/\sqrt{2}$ state, while $f_2^*(1525)$ is dominantly $s\bar{s}$ [9].

As a nonperturbative method, the QCD sum rules is a well established technique in the hadron physics since it is based on the fundamental QCD Lagrangian [10]. The semileptonic decays of $B$ to the light mesons involving $\pi$, $K(K^*, K_0^*)$, and $a_1$ have been studied via the three-point QCD sum rules (3PSR), for instance, $B \to \pi \ell \nu$, $B \to K \ell^+ \ell^-$, $B \to K^* \ell^+ \ell^-$ [12–14], $B \to K_0^* \ell^+ \ell^-$ [15], $B \to (K_0^*, f_2)\ell^+ \ell^-$ [16], and $B \to a_1 \ell^+ \ell^-$ [17]. The determination of the form factor value $T_1(0) = 0.35 \pm 0.05$ relevant for the $B \to K^* \gamma$ and $B \to K^* \ell^+ \ell^-$ [14, 18] decays allowed prediction of the ratio $\Gamma(B \to K^* \gamma)/\Gamma(b \to s \gamma) = 0.17 \pm 0.03$, which agrees with the experimental measurements [19–21]. The obtained results of the decay $B \to \pi \ell \nu$ [11] and simulations on the lattice [22–24] are in a reasonable agreement.

In this work, we investigate $B(B_s) \to K_2^*(a_2, f_2)\ell \nu$ decays within the 3PSR method. For analysis of these decays, the form factors and their branching ratio values are calculated. So far, the form factors of the semileptonic decays $B(B_s) \to K_2^*(a_2, f_2)\ell \nu$ have been studied via different approaches such as the LCSR [25], the perturbative QCD (PQCD) [5], the large energy effective theory (LEET) [26–28], and the ISGW II model [29]. A comparison of our results for the form factor values in $q^2 = 0$ and branching ratio data with predictions obtained from other approaches, especially the LCSR, is also made.

The plan of the present paper is as follows: the 3PSR approach for calculation of the relevant form factors of $B(B_s) \to K_2^*(a_2, f_2)\ell \nu$ decays is presented in Section 2. In the final section, the value of the form factors in $q^2 = 0$ and the branching ratio of the considered decays are reported. For a better analysis, the form factors and differential branching
2. Theoretical Framework

In order to study $B(B_s) \rightarrow K^* \ell \nu$ decays, we focus on the exclusive decay $B_s \rightarrow K^*_2$ via the 3PSR. The $B_s \rightarrow K^*_2 \ell \nu$ decay governed by the tree level $b \rightarrow u$ transition (see Figure 1). In the framework of the 3PSR, the first step is appropriate definition of correlation function. In this work, the correlation function should be taken as

$$\Pi_{\alpha\beta\mu} (p^2, p'^2, q^2) = i \int \int e^{i (p' \cdot x - p \cdot y)} \langle 0 | f_{K^*_2}^\alpha (x) j_\mu (0) f_{B_s}^\beta (y) | B_s (p) \rangle \langle B_s (p) | j^{B_s} (0) | 0 \rangle \, dx \, dy,$$

where $p$ and $p'$ are four-momentum of the initial and final mesons, respectively, $q^2$ is the squared momentum transfer and $T$ is the time ordering operator. $j_\mu = \bar{u} \gamma_\mu (1 - \gamma_5) b$ is the transition current. $j^{B_s}$ and $f_{K^*_2}$ are the interpolating currents of $B_s$ and the tensor meson $K^*_2$, respectively. With considering all quantum numbers, their interpolating currents can be written as follows [33]:

$$j^{B_s} (y) = \bar{b} (y) \gamma_5 \gamma_\mu (y),$$

$$f_{K^*_2}^\alpha (x)$$

$$= \frac{i}{2} \left[ \bar{s} (x) \gamma_\mu \bar{D}_\mu^a (x) u (x) + \bar{s} (x) \gamma_\mu \bar{D}_\mu^a (x) u (x) \right],$$

where $\bar{D}_\mu (x)$ is the four-derivative vector with respect to $x$ acting at the same time on the left and right. It is given as

$$\bar{D}_\mu (x) = \frac{1}{2} \left[ \bar{D}_\mu (x) - \bar{D}_\mu (x) \right],$$

$$\bar{D}_\mu (x) = \bar{D}_\mu (x) - i \frac{\alpha}{2} \lambda^a \Lambda^a \Lambda^a (x),$$

where $\lambda^a$ and $A^a (x)$ are the Gell-Mann matrices and the external gluon fields, respectively. It should be noted that the second current in (2) interpolates a spin 2 particle for massless quarks. In the general case, to describe a spin 2 state one has to use a current such that the trace of $f_{K^*_2}$ vanishes.

The correlation function is a complex function of which the imaginary part comprises the computations of the phenomenology and real part comprises the computations of the theoretical part (QCD). By linking these two parts via the dispersion relation, the physical quantities are calculated. In the phenomenological part of the QCD sum rules approach, the correlation function in (1) is calculated by inserting two complete sets of intermediate states with the same quantum numbers as $B_s$ and $K^*_2$. After performing four integrals over $x$ and $y$, it will be

$$\Pi_{\alpha\beta\mu} = - \frac{\langle 0 | f_{K^*_2}^\alpha | K^*_2 \rangle \langle K^*_2 \rangle | j_\mu | B_s (p) \rangle \langle B_s (p) | j^{B_s} | 0 \rangle}{(p^2 - m^2_B)} + \text{higher states.}$$

In (4), the vacuum to initial and final meson state matrix elements is defined as

$$\langle 0 | f_{K^*_2}^\alpha | K^*_2 \rangle \langle K^*_2 \rangle | j_\mu | B_s (p) \rangle \langle B_s (p) | j^{B_s} | 0 \rangle$$

$$= - \frac{f_{B_s} m^2_{B_s}}{m_B^2 + m_s^2},$$

where $f_{B_s}$ and $f_{K^*_2}$ are the leptonic decay constants of $K^*_2$ and $B_s$ mesons, respectively. $\epsilon_{\alpha\beta}$ is polarization tensor of $K^*_2$. The transition current gives a contribution to these matrix elements and it can be parametrized in terms of some form factors using the Lorentz invariance and parity conservation. The correspondence between a vector meson and a tensor meson allows us to get these parametrizations in a comparative way (for more information see [5]). The parametrization of $B \rightarrow T$ form factors is analogous to the $B \rightarrow V$ case except that $\epsilon$ is replaced by $\epsilon_T$, as follows:

$$\epsilon_T \langle K^*_2 \rangle \langle p', \epsilon | \bar{u} \gamma_\mu (1 - \gamma_5) b | B_s (p) \rangle$$

$$= - i \epsilon^*_{\mu} (m_{B_s} + m_{K^*_2}) A_1 (q^2)$$

$$+ i (p + p')_{\mu} (\epsilon_T \cdot q) \frac{A_2 (q^2)}{m_{B_s} + m_{K^*_2}}.$$
Now, the QCD part of the correlation function is calculated by expanding it in terms of the OPE at large negative value of $q^2$ as follows:

$$\Pi_{a\beta\mu} = C^{(0)}_{a\beta\mu} I + C^{(3)}_{a\beta\mu} \left\langle 0 \mid \overline{\Psi} \gamma \cdot q \Psi \mid 0 \right\rangle + C^{(4)}_{a\beta\mu} \left\langle 0 \mid \overline{\Psi} \gamma_{\mu \nu} G^{\nu \rho} \gamma^\rho \Psi \mid 0 \right\rangle + \cdots,$$

where $C^{(0)}_{a\beta\mu}$ are the Wilson coefficients, $I$ is the unit operator, $\overline{\Psi}$ is the local fermion field operator, and $G^{\nu \rho}_a$ is the gluon strength tensor. In (11), the first term is contribution of the perturbative and the other terms are contribution of the nonperturbative part.

To compute the portion of the perturbative part (Figure 1), using the Feynman rules for the bare loop, we obtain

$$C^{(0)}_{a\beta\mu} = -\frac{i}{4} \int e^{(p' \cdot x - p \cdot y)} \left\{ Tr \left[ S_a (x - y) \gamma_\mu D_\beta (x) \right] + \left[ \gamma_\mu \right] \right\} d^4 x d^4 y,$$

taking the partial derivative with respect to $x$ of the quark free propagators and performing the Fourier transformation and using the Cutkosky rules, that is, $1/(p^2 - m^2) \rightarrow -2i\pi \delta(p^2 - m^2)$, imaginary part of $C^{(0)}_{a\beta\mu}$ is calculated as

$$\text{Im} \left[ C^{(0)}_{a\beta\mu} \right] = \frac{1}{8\pi} \int \delta \left( k^2 - m_a^2 \right) \delta \left( (p + k)^2 - m_b^2 \right) \delta \left( (p' + k)^2 - m_a^2 \right) \cdot \frac{1}{2k \cdot p} \cdot \frac{1}{2k \cdot p'} \cdot \text{Tr} \left[ \left( \gamma_\mu \gamma_5 \right) \gamma_\beta \right] + \left[ \gamma_\mu \right] \cdot \text{Tr} \left[ \gamma_\mu \gamma_5 \right] \cdot \text{Tr} \left[ \gamma_\beta \right] d^4 k,$$

where $k$ is four-momentum of the spectator quark $s$. To solve the integral in (13), we will have to deal with the integrals such as $I_0$, $I_\alpha$, $I_{a\beta\mu}$ and $I_{a\beta\mu}$ with respect to $k$. For example, $I_{a\beta\mu}$ can be as

$$I_{a\beta\mu} (s, s', q^2) = \int \left[ \frac{1}{2k \cdot p} \cdot \frac{1}{2k \cdot p'} \cdot \text{Tr} \left[ \left( \gamma_\mu \gamma_5 \right) \gamma_\beta \right] + \left[ \gamma_\mu \right] \cdot \text{Tr} \left[ \gamma_\mu \gamma_5 \right] \cdot \text{Tr} \left[ \gamma_\beta \right] d^4 k,$$

where $s = p^2$ and $s' = p'^2$. $I_0$, $I_\alpha$, $I_{a\beta\mu}$ and $I_{a\beta\mu}$ can be taken as an appropriate tensor structure as follows:

$$I_0 = \frac{1}{4\sqrt{\lambda} (s, s', q^2)},$$

$$I_\alpha = B_1 [p_{\alpha}] + B_2 [p'_{\alpha}].$$
The diagrams of the effective contributions of the condensate terms are depicted in Figure 2. After some calculations, the nonperturbative part of the correlation function is obtained as follows:

\[
C_{i}^{(0)} = \frac{\rho_{i}(s', q^2) \, ds' \, ds}{(s - p^2)(s' - p'^2)}
\]

Using the dispersion relation, the perturbative part contribution of the correlation function can be calculated as follows:

\[
C_{i}^{(0)} = \int \rho_{i}(s', q^2) \, ds' \, ds.
\]

For calculation of the nonperturbative contributions (condensate terms), we consider the condensate terms of dimensions 3, 4, and 5 related to the contributions of the quark–quark, gluon–gluon, and quark–gluon condensate, respectively. They are more important than the other terms in the OPE. In the 3PSR, when the light quark is a spectator, the gluon–gluon condensate contributions can be easily ignored [35]. On the other hand, the quark condensate contributions of the light quark, which is a nonspectator, are zero after applying the double Borel transformation with respect to both variables \(p^2\) and \(p'^2\), because only one variable appears in the denominator. Therefore, only two important diagrams of dimensions 3, 4, and 5 remain from the nonperturbative part contributions. The diagrams of these contributions corresponding to \(C_{i}^{(3)}\) and \(C_{i}^{(5)}\) are depicted in Figure 2.

The quantities \(\lambda(s, s', q^2)\), \(B_l (l = 1, 2)\), \(D_j (j = 1, \ldots, 4)\), and \(E_r (r = 1, \ldots, 6)\) are indicated in Appendix. Using the relations in (15), \(\text{Im}[C_{0}^{(0)}]\) can be calculated for each structure corresponding to (9) as follows:

\[
\text{Im}\left[C_{0}^{(0)}\right] = \rho_{V} \left(\rho_{b\mu} \rho_{a\nu} + \rho_{b\mu} \rho_{a\nu}' + \rho_{a\mu} \rho_{b\nu}' + \rho_{a\mu} \rho_{b\nu}\right)
\]

where the spectral densities \(\rho_{i}\) \((i = V, 0, 1, 2)\) are found as

\[
\rho_{V} (s, s', q^2) = 24B_{1} \sqrt{x} \left[B_{1} (m_s - m_b) + B_{2} (m_{s'} - m_b) + B_{3} (m_{s'} - m_s) + 2B_{1} m_s - 2E_{4} (m_{s'} - m_s)\right]
\]

\[
\rho_{0} (s, s', q^2) = 12 \left[D_{2} (m_s - m_b) + D_{3} (m_{s'} - m_s) - m_s (m_s + m_{s'} - m_b)\right]
\]

\[
\rho_{1} (s, s', q^2) = 3B_{1} \left[2m_s^2 (m_s + m_{s'} - m_b)\right]
\]

\[
\rho_{2} (s, s', q^2) = 24 \left[D_{2} m_s + E_{3} (m_s - m_b)\right].
\]

The diagrams of the effective contributions of the condensate terms.

\[
I_{a\beta} = D_{1} \left[g_{a\beta} + D_{2} (p_{a} p_{\beta}) + D_{3} (p_{a} p_{\beta} + p_{a} p_{\beta} + p_{a} p_{\beta})\right]
\]

\[
I_{a\beta\mu} = E_{1} \left[g_{a\beta\mu} + g_{a\mu} p_{\beta} + g_{\beta\mu} p_{a}\right]
\]

\[
+ E_{2} \left[g_{a\beta} p_{\mu} + g_{a\mu} p_{\beta} + g_{\beta\mu} p_{a}'\right]
\]

\[
+ E_{3} \left[p_{a} p_{\beta} + p_{a} p_{\beta} + p_{a} p_{\beta} + p_{a} p_{\beta}\right]
\]

\[
+ E_{4} \left[p_{a} p_{\beta} p_{\mu} + p_{a} p_{\beta} p_{\mu} + p_{a} p_{\beta} p_{\mu} + p_{a} p_{\beta} p_{\mu}\right]
\]

\[
+ E_{5} \left[p_{a} p_{\beta} p_{\mu} + p_{a} p_{\beta} p_{\mu} + p_{a} p_{\beta} p_{\mu} + p_{a} p_{\beta} p_{\mu}\right]
\]

\[
+ E_{6} \left[p_{a} p_{\beta} p_{\mu} + p_{a} p_{\beta} p_{\mu} + p_{a} p_{\beta} p_{\mu} + p_{a} p_{\beta} p_{\mu}\right].
\]
value of the condensates at a fixed renormalization scale of about 1 GeV [36, 37].

The next step is to apply the Borel transformations with respect to $p^2$ ($p^2 \to M^2_1$) and $p'^2$ ($p'^2 \to M^2_2$) on the phenomenological as well as the perturbative and nonperturbative parts of the correlation functions and equate these two representations of the correlations. The following sum rules for the form factors are derived:

$$V'(q^2) = \frac{(m_b + m_s) e^{m_b^2/M_1^2} e^{m_s^2/M_2^2}}{f_{B_s} m_B M_1 m_{K^*_s} M_2} \left\{ -\frac{1}{(2\pi)^2} \right\}$$

$$+ B \left[ C_V^{(3)} + C_V^{(4)} \right] ds' ds,$$

$$A_n'(q^2) = \frac{(m_b + m_s) e^{m_b^2/M_1^2} e^{m_s^2/M_2^2}}{f_{B_s} m_B M_1 m_{K^*_s} M_2} \left\{ -\frac{1}{(2\pi)^2} \right\}$$

$$+ B \left[ C_n^{(3)} + C_n^{(4)} \right] ds' ds,$$

where $n = 0, 1, 2$ and $s_0$ and $s'_0$ are the continuum thresholds in the initial and final channels, respectively. The lower limit in the integration over $s$ is $s_L = m_0^2 + (m_0^2 - q^2) s'$. Also, $\bar{B}$ transformation is defined as follows:

$$\bar{B} \left[ \frac{1}{(p^2 - m_b^2)^m (p'^2 - m_s^2)^n} \right] = (-1)^{m+n} e^{-m_b^2/M_1^2} e^{-m_s^2/M_2^2} \frac{\Gamma(n) \Gamma(m)}{\Gamma(n+m) (M_1^2)^{m-1} (M_2^2)^{n-1}},$$

3. Numerical Analysis

In this section, we numerically analyze the sum rules for the form factors $V(q^2)$, $A_0(q^2)$, $A_1(q^2)$, and $A_2(q^2)$ as well as branching ratio values of the transitions $B(B_s) \to T$, where $T$ can be one of the tensor mesons $K^*_s$, $a_2$, or $f_2$. The values of the meson masses and leptonic decay constants are chosen as presented in Table 1. Also, $m_b = 4.820$ GeV, $m_t = 0.150$ GeV [38], $m_c = 1.776$ GeV, and $m_\mu = 0.105$ GeV [30].

From the 3PSR, it is clear that the form factors also contain the continuum thresholds $s_0$ and $s'_0$ and the Borel parameters $M_1^2$ and $M_2^2$ as the main input. These are not physical quantities; hence the form factors should be independent of these parameters. The continuum thresholds, $s_0$ and $s'_0$, are not completely arbitrary, but these are in correlation with the energy of the first exiting state with the same quantum numbers as the considered interpolating currents. The value of the continuum threshold $s_0^{R(B)} = 35$ GeV [39] is calculated from the 3PSR. The values of the continuum threshold $s'_0$ for the tensor mesons $K^*_s$, $a_2$, and $f_2$ are taken to be $s'_0 = 3.13$ GeV, $s'_0 = 2.70$ GeV, and $s'_0 = 2.53$ GeV, respectively [9]. In this work, the variations of $s_0^T (T = a_2, K^*_s, f_2)$ are considered to be ±0.2. In these regions, the dependence of the form factors on the continuum threshold values is very small. For instance, we have shown the variations of the form factor $A_{1,2}^{B_s \to K^*}(q^2)$ for different values of $s_0$ in Figure 3. As can be seen, these plots are very close to each other.

We search for the intervals of the Borel parameters so that our results are almost insensitive to their variations. One more condition for the intervals of these parameters is the fact that the aforementioned intervals must suppress the higher states, continuum, and contributions of the highest-order operators. In other words, the sum rules for the form factors must converge. As a result, we get $8 \text{ GeV}^2 \leq M_1^2 \leq 12 \text{ GeV}^2$ and $4 \text{ GeV}^2 \leq M_2^2 \leq 8 \text{ GeV}^2$. To show how the form factors depend on the Borel mass parameters, as examples, we depict the variations of the form factors $V$, $A_0$, $A_1$, and $A_2$ for $B_s \to K^*_s \ell^+ \nu$ at $q^2 = 0$ with respect to the variations of the $M_1^2$ and $M_2^2$ parameters in their working regions in Figure 4. From these figures, it is revealed that the form factors weakly depend on these parameters in their working regions.

In the Borel transform scheme, the ratio of the nonperturbative to perturbative part of the form factor $V^{B_s \to K^*}$ is about $V^{non-per}(0)/V^{per}(0) = 13\%$. This value confirms that the higher order corrections are small, constituting a few percent, and can easily be neglected. Our calculation shows that the same suppression is observed for all other form factors.

The sum rules for the form factors are truncated at about $0 \leq q^2 \leq 11 \text{ GeV}^2$. The dependence of the form factors $V$, $A_0$, 

| Meson | $B_s$ | $B$ | $K^*_s$ | $a_2$ | $f_2$ |
|-------|-------|-----|---------|------|------|
| Mass  | 5.366 | 5.279 | 1.425   | 1.318 | 1.275 |
| Decays| 0.222 ± 0.012 | 0.186 ± 0.014 | 0.118 ± 0.005 | 0.107 ± 0.006 | 0.102 ± 0.006 |

Table 1: The values of the meson masses [30] and decay constants [31, 32] in GeV.
Figure 3: The form factor of $A_1^{B \rightarrow K^*}$ on $q^2$ for different values of $s_0^2$.

The values of the parameters $f(0)$, $a$, and $b$ for the transition form factors of $B \rightarrow T$ are given in Table 2.

In Table 3, our results for the form factors of $B \rightarrow T \ell \nu$ in $q^2 = 0$ are compared with those of other approaches such as the LCSR, the PQCD, and the ISGW II model. Our results are in good agreement with those of the LCSR, PQCD, and LEET in all cases.

At the end of this section, we would like to present the differential decay widths of the process under consideration. Using the parametrization of these transitions in terms of the form factors, the differential decay width for $B \rightarrow T \ell \nu$ transition is obtained as

$$d\Gamma (B \rightarrow T \ell \nu) = \frac{|G_F V_{ub}|^2 \sqrt{\lambda (m_B^2, m_T^2, q^2)}}{256 m_B^3 r^3 q^2} \left( 1 - m_T^2 / q^2 \right)^2 (X_L + X_+ + X_-)$$

$$f\left( q^2 \right) = \frac{f(0)}{1 - a \left( q^2 / m_{BR(b)}^2 \right) + b \left( q^2 / m_{BR(a)}^2 \right)^2}$$

(23)

where $m_\ell$ represents the mass of the charged lepton. The other parameters are defined as

$$X_L = \frac{\lambda}{9 m_B^2 m_T} \left[ (2q^2 + m_T^2) h_0(q^2) + 3\lambda m_\ell^2 A_1(q^2) \right]$$

(24)

$$X_\pm = \frac{2q^2}{3} \left( 2q^2 + m_\ell^2 \right) \frac{\lambda}{8m_T^2 m_B} \left[ (m_B + m_T) A_1(q^2) - \frac{\sqrt{\lambda}}{m_B + m_T} V(q^2) \right]^2$$

(25)

Integrating (24) over $q^2$ in the whole physical region and using $V_{ub} = (3.89 \pm 0.44) \times 10^{-3}$ [30], the branching ratios of the $B \rightarrow T \ell \nu$ are obtained. The differential branching ratios of the $B \rightarrow T \ell \nu$ decays on $q^2$ are shown in Figure 6. The branching ratio values of these decays are also obtained as presented in Table 4. Furthermore, this table contains the results estimated via the PQCD. Considering the uncertainties, our estimations for the branching ratio values of the $B \rightarrow T \ell \nu$ decays are in consistent agreement with those of the PQCD.

Table 2: Parameter values appearing in the fit functions of the $B \rightarrow T \ell \nu$ decays.

| Form factor | $f(0)$ | $a$ | $b$ |
|-------------|--------|-----|-----|
| $Y_1^{B \rightarrow K^*}$ | 0.13 | 2.19 | 0.83 |
| $A_1^{B \rightarrow K^*}$ | 0.10 | 1.36 | 0.09 |
| $Y_1^{B \rightarrow K^*}$ | 0.13 | 2.10 | 0.75 |
| $A_1^{B \rightarrow K^*}$ | 0.11 | 1.45 | 0.23 |
| $Y_1^{B \rightarrow f_1}$ | 0.12 | 2.01 | 0.60 |
| $A_1^{B \rightarrow f_1}$ | 0.10 | 1.40 | 0.16 |
| $A_1^{B \rightarrow f_2}$ | 0.23 | 3.77 | 4.21 |
| $A_1^{B \rightarrow f_2}$ | 0.05 | 0.21 | -2.99 |
| $A_1^{B \rightarrow f_2}$ | 0.26 | 3.71 | 4.03 |
| $A_1^{B \rightarrow f_2}$ | 0.09 | 0.63 | 0.46 |
| $A_1^{B \rightarrow f_2}$ | 0.24 | 3.70 | 4.02 |
| $A_1^{B \rightarrow f_2}$ | 0.09 | 0.46 | 0.29 |

In summary, we considered $B (B \rightarrow K^*_2 (a_2, f_2)) \ell \nu$ channels and computed the relevant form factors considering the contribution of the quark condensate corrections. Our results are in good agreement with those of the LCSR, PQCD, and LEET in all cases. We also evaluated the total decays widths and the branching ratios of these decays. Our branching ratio values of these decays are in consistent agreement with those of the PQCD.

| Br ($B \to f_{j} \tau\nu$) | 0.35 ± 0.11 | 0.25^{+0.17}_{-0.12} |

Appendix

In this appendix, the explicit expressions of the coefficients $\lambda(s, s', q^2)$, $B_l (l = 1, 2)$, $D_j (j = 1, \ldots, 4)$, and $E_r (r = 1, \ldots, 6)$ are given.

\[ \lambda(s, s', q^2) = s^2 + s'^2 + (q^2)^2 - 2qsq^2 - 2s'q^2 - 2ss', \]

\[ B_1 = \frac{I_0}{\lambda(s, s', q^2)} \left[ 2s'\Delta - \Delta' u \right], \]

\[ B_2 = \frac{I_0}{\lambda(s, s', q^2)} \left[ 2s\Delta' - \Delta u \right], \]

\[ D_1 = -\frac{I_0}{2\lambda(s, s', q^2)} \left[ 4ss'm^2_s - 2ss'\Delta' - s'\Delta^2 - u'm^2_s + u\Delta' \right], \]

\[ D_2 = -\frac{I_0}{\lambda^2(s, s', q^2)} \left[ 8ss'^2m^2_s - 2ss'\Delta' + 6s'^2\Delta^2 - 2u^2m^2_s + 6s'u\Delta' - u'^2\Delta'^2 \right], \]

\[ D_3 = \frac{I_0}{\lambda^2(s, s', q^2)} \left[ 4ss'um^2_s + 4ss'\Delta'\Delta - 3su\Delta'^2 - 3u^2s' - u^3m^2_s + 2u^2\Delta' \right], \]
Form factors ($B_s \rightarrow K^*_2$)

Figure 5: The SR predictions for the form factors of the $B(B_s) \rightarrow T\ell\nu$ transitions on $q^2$.

Form factors ($B \rightarrow a^2$)

Form factors ($B \rightarrow f^2$)

Figure 6: The differential branching ratios of the semileptonic $B \rightarrow T\ell\nu$ decays on $q^2$. 
\[ D_4 = \frac{I_0}{\lambda^2(s, s', q^2)} \left[ -6s' u \Delta \Delta' + 6s^2 \Delta'^2 - 8s^2 s' m_i^2 + 2u^2 s m_i^2 + u^2 \Delta^2 + 2s s' \Delta^2 \right], \]

\[ E_1 = \frac{I_0}{2\lambda^2(s, s', q^2)} \left[ 8s^2 m_i^2 \Delta s - 2s' m_i^2 \Delta u^2 - 4u m_i^2 \Delta s' + u^3 \Delta s' - 2s^2 \Delta^3 + 3s' u \Delta^2 \Delta' - 2\Delta^2 \Delta' ss' - \Delta^2 \Delta' u^2 + u \Delta^4 \right], \]

\[ E_2 = \frac{I_0}{2\lambda^2(s, s', q^2)} \left[ 8s^2 m_i^2 \Delta' s' - 2s^2 \Delta'^3 - 4u m_i^2 \Delta s' - 2\Delta^2 \Delta' ss' + 3us \Delta'^2 - 2sm_i^2 \Delta' u^2 + s' u \Delta^3 + u^3 m_i^2 \Delta - \Delta^2 \Delta' u^2 \right], \]

\[ E_3 = -\frac{I_0}{\lambda^3(s, s', q^2)} \left[ 48s m_i^2 \Delta s^3 - 24s s' u m_i^2 \Delta' \right. \]

\[ - 12s' \Delta^2 \Delta' + 6su \Delta^3 \Delta' - 20s^3 \Delta^3 + 30s^2 u \Delta^2 \Delta' \]

\[ - 12s' m_i^2 \Delta u^2 - 12s' \Delta^2 \Delta' u^2 + 6u^2 s m_i^2 \Delta' + u^3 \Delta'^3 \right], \]

\[ E_4 = -\frac{I_0}{\lambda^3(s, s', q^2)} \left[ 16s^2 m_i^2 \Delta s^2 - 4s^2 \Delta^3 \Delta' \right. \]

\[ - 12s' \Delta^2 \Delta' + 24s s' u m_i^2 \Delta' + 3u \Delta^2 \Delta' \]

\[ + 18su \Delta^2 \Delta' + 4s \Delta^3 u^2 + 10s^2 u \Delta^3 + 6s u^3 m_i^2 \Delta' \]

\[ - 12s' \Delta^2 \Delta' u^2 - 2m_i^2 \Delta' u^4 + 4s s' u^2 m_i^2 \Delta' \right], \]

\[ E_5 = -\frac{I_0}{\lambda^3(s, s', q^2)} \left[ 16s^2 m_i^2 \Delta s^2 - 24s s' u m_i^2 \Delta' \right. \]

\[ - 12s' \Delta^2 \Delta' + 10us \Delta^3 \Delta' - 4s s^2 \Delta'^3 + 4s \Delta^2 \Delta' u^2 \]

\[ + 18su \Delta^2 \Delta' + 6u^2 m_i^2 \Delta' - 12s \Delta^2 \Delta' u^2 - 4s^2 \Delta^2 u^2 \]

\[ - 2m_i^2 \Delta u^4 + 3u \Delta^2 \Delta'^3 \right], \]

\[ E_6 = -\frac{I_0}{\lambda^3(s, s', q^2)} \left[ 48s m_i^2 \Delta s^3 - 20s^3 \Delta' \right. \]

\[ - 12s^2 \Delta^2 \Delta' s' - 24s^2 s' u m_i^2 \Delta - 12s^2 m_i^2 \Delta' u^2 \]

\[ + 30s^2 \Delta^2 \Delta' + 6su^3 \Delta' s' - 12s \Delta^2 \Delta' u^2 + 6u^3 m_i^2 \Delta \]

\[ + u^3 \Delta'^3 \right], \]

\[ \Delta = s + m_i^2 - m_h^2, \Delta' = s' + m_i^2 - m_h^2, \ u = s + s' - q^2. \]
