Abstract. We study alternating strand diagrams on the disk with an orbifold point. These are quotients by rotation of Postnikov diagrams on the disk, and we call them orbifold diagrams. We associate a quiver with potential to each orbifold diagram, in such a way that its Jacobian algebra and the one associated to the covering Postnikov diagram are related by a skew-group algebra construction. We moreover realise this Jacobian algebra as the endomorphism algebra of a certain explicit cluster-tilting object. This is similar to (and relies on) a result by Baur-King-Marsh for Postnikov diagrams on the disk.

1. Introduction

In this article we study orbifold diagrams, i.e. alternating strand diagrams on the disk with an orbifold point. These are collections of oriented arcs satisfying certain properties, which we define as quotients by rotation of alternating strand diagrams on the disk (also called Postnikov diagrams). The latter have been used in the study of the coordinate ring of the Grassmannian: they give rise to clusters of the Grassmannian cluster algebras, [Sco06], or to cluster tilting objects of the Grassmannian cluster categories [JKS16], [BKM16]. On the other hand, orbifolds have also been related to cluster structures, [PS19], [CS14]. In [AP21], Amiot and Plamondon construct cluster algebras on surfaces with orbifold points of order 2, and in their construction skew-group algebras appear naturally. Here we associate quivers with potentials to orbifold diagrams in such a way that skew-group algebras play a major role.

Skew group construction have been used in representation theory, for example in the seminal work of Reiten and Riedtmann [RR85] and of Asashiba [Asa11]. In [LFV19], the authors consider the triangulated disk with one orbifold point of order three. However in their set-up, the authors do not need skew group constructions because the action considered is free. The authors obtain a generalised cluster algebra from the Jacobian algebra associated to each triangulation of the aforementioned triangulated orbifold. Let us point out there is a well-known relation between triangulated surfaces and certain Postnikov diagram, see [BKM16, Section 13], first described for the disk by Scott in her work [Sco06, Section 3]. This relation allow us to expect a generalised cluster structure from the constructions we give in this paper. We will investigate this in future work.

Our set-up is the following. We start with Postnikov diagrams with rotational invariance, i.e. with an action of a cyclic group $G$ of order $d$, and take the quotient with respect to this action. We also give an intrinsic definition of such a quotient as a new combinatorial datum associated to a disk with an orbifold point, and call this an orbifold diagram. We associate a quiver with potential $(Q_{\mathcal{O}}, W_{\mathcal{O}})$ to every orbifold diagram $\mathcal{O}$, with a construction that depends on whether the orbifold point corresponds to a vertex of the quiver or not. In particular, we give a construction in case the action is not free on vertices. In Proposition 6.1 we prove that the frozen Jacobian algebras $A_{\mathcal{O}}$ of this new quiver and the one of the associated Postnikov diagram are related by a skew-group construction.

We then restrict to the case where the permutation induced by the strands of the associated Postnikov diagram on the cover is of Grassmannian type $(k, n)$, to use results from [JKS16, BKM16]. As for Postnikov diagrams, there is an idempotent subalgebra $B(\mathcal{O})$ of the frozen Jacobian algebra $A(\mathcal{O})$ that only depends on $(k, n, d)$.

Our aim is to realise the frozen Jacobian algebra as an endomorphism algebra of a cluster tilting object as in the statement in [BKM16, Theorem 10.3]. To do this, we construct modules over the idempotent algebra $B(\mathcal{O})$ of an orbifold diagram in such a way that they are the images of the rank 1 modules from [JKS16] under a canonical functor.

Any orbifold diagram determines a collection of such modules whose direct sum is a cluster-tilting objects in a Frobenius, stably 2-Calabi-Yau category. Our main result, Theorem 6.23, is that the endomorphism ring of this cluster-tilting object is isomorphic to $A(\mathcal{O})$.

Conventions. We always consider finitely generated left modules and we compose arrows from right to left. The base field is the complex numbers.

The authors thank the referees for their careful work and for their useful suggestions

2. Orbifold diagrams

In this section, we define orbifold diagrams on the disk with an orbifold point. Informally, these are quotients of rotation-invariant Postnikov diagrams, also called alternating strand diagrams. We start by defining these, following [Pos06].

We write $S_n$ for the symmetric group of permutations of $n$ elements.

Definition 2.1. A Postnikov diagram of type $\sigma \in S_n$ is a collection of $n$ oriented curves $\gamma_i$, called strands, on a disk with $n$ marked points on the boundary (clockwise labeled $1, \ldots, n$), such that

1. The strand $\gamma_i$ connects the boundary point $i$ with $\sigma(i)$, starting at $i$. The strand $\gamma_i$ intersects the boundary only in those two (possibly coinciding) points.
2. There are a finite number of crossings, all between two strands, all transverse.
3. Following a strand, the strands crossing it come alternatingly from the left and from the right. This includes strands crossing at boundary points.
4. If two strands cross in two points $A$ and $B$, then one is oriented from $A$ to $B$ and the other is oriented from $B$ to $A$. This also applies to crossings at boundary points.
5. If a strand crosses itself other than at a boundary point, then consider the disk determined by the loop. No strand intersects the interior of this disk.

A Grassmannian Postnikov diagram of type $(k, n)$ is a Postnikov diagram satisfying the additional condition

6. The permutation $\sigma \in S_n$ is given by $\sigma(i) = i + k \pmod n$.

Postnikov diagrams are considered modulo isotopy fixing the boundary.

Remark 2.2. Postnikov diagrams can be reduced as follows, see Figure 1:

(i) If two strands cross in points $A$ and $B$ such that the region formed by $A$ and $B$ is simply connected then we can reduce by “pulling the strands” in a way to remove the two crossings. Note that one of the points $A$ and $B$ may be a marked point on the boundary; in that case, only one crossing gets removed.
(ii) If a strand crosses itself and if the disk determined by the loop contains no other strands, the strand can be straightened, i.e. the crossing removed.

Diagrams reduced in this way retain many properties of the original diagram, and so we will often assume in the following that Postnikov diagrams are reduced.

Since we plan to take quotients by rotations of the disk, an important role is played by the Postnikov diagrams which are rotation-invariant. These were first studied in [Pas20] in relation to self-injective Jacobian algebras.
Definition 2.3. A Postnikov diagram of type $\sigma \in S_n$ is d-symmetric if it is (up to isotopy) invariant under rotation by $\frac{2\pi}{d}$.

Observe that in this case $\mathbb{Z}_d$ must act freely on \{1, \ldots, n\}, and so $d \mid n$.

Example 2.4. Figure 2 shows examples of Postnikov diagrams. The first is of type with an orbifold point of order $d$ quotient by the cyclic group of order $d$, the second is a symmetric Postnikov diagram of type (4, 10). The last is a symmetric Grassmannian Postnikov diagram of type (4, 10).

If we start with a $d$-symmetric Postnikov diagram of order $d > 1$, we can construct its (topological) quotient by the cyclic group of order $d$ acting by rotations. This will be a collection of curves on a disk with an orbifold point of order $d$. The resulting diagram is what we will call an “orbifold diagram”.

We first give an abstract definition of a (weak) orbifold diagram and introduce orbifold diagrams in Definition 2.12. We will then show that orbifold diagrams as defined through this are the same as quotients of symmetric Postnikov diagrams (Proposition 2.14).

Notation 2.5. We will use the usual notion of winding number for a closed curve with respect to a point, but the clockwise direction is for us positive. This is because in the literature the boundary points are usually labeled clockwise.

Let $\Sigma$ be a disk with $n_0$ marked points on the boundary (clockwise labeled 1, $\ldots$, $n_0$) and an orbifold point $\Omega$ of order $d > 1$.

Definition 2.6. A weak orbifold diagram of type $\tau \in S_{n_0}$ on $\Sigma$ is a collection of $n_0$ oriented curves $\gamma_i$, called strands, on $\Sigma$, such that

1. The strand $\gamma_i$ connects the boundary point $i$ with $\tau(i)$, starting from $i$. The strand $\gamma_i$ intersects the boundary only in those two (possibly coinciding) points, and does not go through $\Omega$.
2. There is a finite number of crossings, all between two strands, all transverse.
3. Following a strand, the strands crossing it come alternatingly from the left and from the right. This includes strands crossing at boundary points.
4. If two strands cross in two points $A$ and $B$ and both are oriented from $A$ to $B$, then consider the closed curved formed by following a strand from $A$ to $B$ and then following the other strand in the opposite direction from $B$ to $A$. The winding number of this closed curve with respect to $\Omega$ is not 0 (for an example, see the curves between the points $Q_1$ and $Q_2$ in both pictures in Figure 7).
5. If a strand crosses itself, then consider the closed curve formed by following the strand from a point of intersection to itself. Either this has nonzero winding number with respect to $\Omega$, or it is a simple loop not intersecting any other strand (and thus can be reduced as for Postnikov diagrams).

Weak orbifold diagram are considered up to isotopy fixing the boundary and the center of the disk.

Figure 3 shows examples of weak orbifold diagrams. Observe that the order $d$ of the orbifold point $\Omega$ does not appear in the axioms: it is part of the datum of the surface. So we can have the same diagram (picture) for varying orders $d$.

Remark 2.7. To any weak orbifold diagram $\mathcal{O}$ on a disk $\Sigma$ we will consider a symmetrized version of $\mathcal{O}$ on the universal cover of $\Sigma$. This depends on the order of $\Omega$, in particular, the same strand configuration (picture) leads to a symmetrized version for every $d > 1$. 

\begin{figure}
\centering
\includegraphics[width=\textwidth]{postnikov.png}
\caption{Examples of Postnikov diagrams. Symmetry axes indicated by dashed lines.}
\end{figure}
Figure 3. Two weak orbifold diagrams; $\tau = \text{id} \in S_2$ on the left, $\tau = (13) \in S_3$ on the right.

**Definition 2.8.** Let $O$ be a (reduced) weak orbifold diagram on $\Sigma$, assume that $\Omega$ has order $d$. Draw a simple curve joining $\Omega$ to the boundary arc between $n_0$ and 1. Then $\text{sym}_d(O)$ is the collection of $n_0d$ strands obtained from taking $d$ copies of $O$ and gluing them along the copies of the simple curve. We draw the resulting surface as a disk and label the marked points by $1, 2, \ldots, n_0, n_0+1, \ldots, dn_0$ clockwise around the boundary.

By construction, the image $\text{sym}_d(O)$ is a collection of $n = n_0d$ strands on a disk (without orbifold points) which is symmetric under rotation by $\frac{2\pi}{d}$. The image $\text{sym}_d(O)$ corresponds to taking the universal cover of the orbifold diagram $O$ for the surface $\Sigma$ with $\Omega$ a point of order $d$.

The result is not a Postnikov diagram in general, as it may have “lenses” (pairs of twice-crossing parallel strands) and self-crossings (compare Definition 2.6 and Definition 2.1). This is illustrated in Example 2.9 below. If $d$ is large enough, the symmetrized version $\text{sym}_d(O)$ of $O$ is a Postnikov diagram, which is $d$-symmetric by construction, see Proposition 2.14.

Note that the the quotient of $\text{sym}_d(O)$ under the rotation by $\frac{2\pi}{d}$ is $O$. We will write $\mathcal{P}/d$ to denote the quotient of a $d$-symmetric Postnikov diagram under the rotation by $\frac{2\pi}{d}$.

Figure 4. A weak orbifold diagram on $\Sigma$, its 2-fold cover in the middle and its 3-fold cover on the right. Red dashed lines indicate the fundamental domains/symmetry axes.

**Example 2.9.** Here we start with a weak orbifold diagram $O$ for $\tau = (13) \in S_3$ on $\Sigma$, with orbifold point $\Omega$ of order $d$, see first picture in Figure 4. We consider $\text{sym}_d(O)$ for $d = 2$ and $d = 3$.

Let us consider the 2-fold cover in Figure 4. This is not a good cover of $O$ for two independent reasons. First, it is not a Postnikov diagram, since it violates condition (4) of Definition 2.1: the strands crossing at $A$ and $B$ are both oriented from $A$ to $B$. This is because the order of the orbifold point (i.e. 2) is too small compared to how much the strands wind around it. In Definition 2.12 we will precisely quantify how large $d$ needs to be for the $d$-fold cover to be a Postnikov diagram.

The second issue is more subtle: the diagram of the 2-fold cover is not reduced, in the sense that we can apply a reduction move as in Remark 2.2. However, the quotient of the reduced diagram by the rotation of order 2 is not the same as $O$ (it corresponds to applying a forbidden reduction move that goes through $\Omega$). This issue arises because the order of the orbifold point is exactly 2. Indeed, the reduction moves are applied to digons, and those arise precisely from covers of order 2. To avoid this, we will stipulate that the order of orbifold diagrams is at least 3, which ensures that if $O$ is reduced then its cover is also reduced.
Finally, the 3-fold cover $\text{sym}_3(O)$ is a 3-symmetric Postnikov diagram: the problems disappear, since 3 is large enough (as per Definition 2.12) and is not equal to 2.

Let us point out that if we start from a $d$-symmetric Postnikov diagram on a disk with $n = n_0d$ marked points and take its quotient under the rotation by $\frac{2\pi}{d}$, we obtain a weak orbifold diagram on a disk $\Sigma$ with $n_0$ points with additional properties, see Example 2.10.

**Example 2.10.** We start with a 5-symmetric Grassmannian Postnikov diagram of type $(4, 10)$, see Figure 5. When we quotient by the 5-fold symmetry we get a weak orbifold diagram on a disk $\Sigma$ with a point $\Omega$ of order 5 and with 2 marked points. The type of the image is $\tau = \text{id}$.

![Figure 5](image5.png)

**Figure 5.** Taking the quotient under rotation by $2\pi/5$ gives a weak orbifold with a point of order 5; red dashed lines indicate symmetry axes/fundamental domains.

**Example 2.11.** Here we have a 3-symmetric Postnikov diagram of type $(3, 9)$. Its quotient by the 3-fold symmetry, on the right, is a weak orbifold diagram on a disk $\Sigma$ with a point $\Omega$ of order 3 and 3 marked points, of type $\tau = \text{id}$.

![Figure 6](image6.png)

**Figure 6.** A symmetric orbifold diagram $\mathcal{P}$ with its quotient $\mathcal{P}/3$ on the right.

We would like to upgrade our definition of weak orbifold diagram by including the value of $d$ in the datum of the picture, as well as guaranteeing that the $d$-fold cover is a Postnikov diagram. The only properties that might fail are (4) and (5) in Definition 2.1. Since for sufficiently large $d$ these properties hold, we pick the smallest such $d$.

Let us define some notation. For a strand $\gamma$ in a weak orbifold diagram, consider its points of self-intersection (including at the boundary). Each of these points $P$ determines a closed subcurve of $\gamma$ (going from $P$ to itself), which has a winding number $w(P)$ with respect to $\Omega$. We define $S(\gamma)$ to be the maximum of the absolute values of $w(P)$, where $P$ varies in the set of self-intersections of $\gamma$. If $\gamma$ does not intersect itself we set $S(\gamma) = 0$. 

Similarly, let $\gamma_1$ and $\gamma_2$ be two strands in an orbifold diagram. Assume that they meet in two points $A$ and $B$, and that they are both oriented from $A$ to $B$. Then consider the curve formed by following $\gamma_1$ from $A$ to $B$ and then $\gamma_2$ against the orientation from $B$ to $A$. This is a closed loop and it has a winding number $w(A, B)$ with respect to $\Omega$. Strictly speaking, this is not well-defined as the sign of $w(A, B)$ depends on the choice of the curve that is taken against the orientation. But we are only interested in the absolute value of $w(A, B)$: We define $L(\gamma_1, \gamma_2)$ to be the maximum of the absolute values of $w(A, B)$ for all pairs $A, B$ as above. We set $L(\gamma_1, \gamma_2) = 0$ if $\gamma_1$ and $\gamma_2$ do not meet as above.

**Definition 2.12.** Let $\Sigma$ be a disk with an orbifold point $\Omega$ of order $d > 1$. A weak orbifold diagram $O$ on $\Sigma$ is an orbifold diagram (of order $d$) if

$$d > \max \{ \max_{\gamma \neq \gamma_2} S(\gamma), \max_{\gamma_1 \neq \gamma_2} L(\gamma_1, \gamma_2) \}.$$  

An orbifold diagram on $\Sigma$ is Grassmannian if $\tau = \text{id}$ and there is an integer $0 < w_+ < d$ such that every strand has winding number $w_+$ or $w_+ - d$. In this case, we say that the orbifold diagram is of type $(k, n)$, where $n = nad$ and $k = n\omega_+$.

**Example 2.13.** We consider the weak orbifold diagrams from Examples 2.9 and 2.10.

1. We first take the weak orbifold diagram $O$ on the left of Figure 7. We want to see whether the conditions of Definition 2.12 hold. The strand $\gamma_1$ does not have self-intersection points, $w(P_2) = 1$ and $w(P_3) = -1$, so $S(\gamma_1) = 0$, $S(\gamma_2) = S(\gamma_3) = 1$. For the second condition: we have $w(Q_1, Q_2) = 2$ and so $L(\gamma_2, \gamma_3) = 2$. Since $d = 3$, $O$ is indeed an orbifold diagram.

2. Now we look at the diagram $O$ on the right of Figure 7. This is a weak orbifold diagram of order $d = 5$ and we want to see whether the conditions of Definition 2.12 hold. We get $w(P_{11}) = 2$, $w(P_{12}) = 1$, $w(P_{21}) = -3$, $w(P_{22}) = -2$ and $w(P_{23}) = -1$. So $S(\gamma_1) = 2$ and $S(\gamma_2) = 3$. We have $w(Q_1, Q_2) = 1$, $w(Q_1, Q_3) = 3$, $w(Q_1, Q_4) = 2$, $w(Q_2, Q_3) = 2$, $w(Q_2, Q_4) = 3$ and $w(Q_3, Q_4) = 1$. In this case $L(\gamma_1, \gamma_2) = 4$. Since $d = 5$, $O$ is also an orbifold diagram.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure7.png}
\caption{Computing the values of the winding numbers, see Definition 2.12.}
\end{figure}

**Proposition 2.14.** Let $O$ be an orbifold diagram of order $d > 2$, and let $P$ be an $s$-symmetric Postnikov diagram (for some $s > 1$). Then:

1. sym$_d(O)$ is a $d$-symmetric Postnikov diagram.
2. $O/s$ is an orbifold diagram on a disk with an orbifold point $\Omega$ of order $s$.
3. sym$_d(O)/d = O$ and, if $s > 2$, sym$_s(O/s) = P$.

**Proof.** Let us begin with (1). First, at every boundary point of sym$_d(O)$ there is exactly one outgoing and one incoming strand, as this is true for $O$. Moreover, since every point on a strand can be reached by walking along a strand on $O$, the same is true for sym$_d(O)$, which means that every piece of curve in sym$_d(O)$ is indeed part of a strand coming from the boundary (i.e. there are no closed strands inside the interior of the disk). So condition (1) of Definition 2.1 is satisfied. Condition (2) holds by construction, as does condition (3) since it is local. Let us examine condition (5). Every self-crossing of a strand $\gamma$ on sym$_d(O)$ comes from a self-crossing of a strand $\eta$ of $O$. Let $\eta'$ be the subcurve of $\eta$ defined by such a crossing, i.e. we start from a crossing point $Q$ and follow $\eta$ until we reach $Q$ again. Thus $\eta'$ is a closed curve in $O$. By condition (5) of Definition 2.6, this either can be reduced or has nonzero winding number. If it can be reduced, so can its images in sym$_d(O)$ and condition (5) is satisfied. So assume that $\eta'$ cannot
be reduced. Then by Definition 2.12, the absolute value of the winding number of \( \eta' \) is strictly less than \( d \). Without loss of generality, this winding number \( w \) is positive, so \( 1 < w < d \).

Call \( c \) the curve connecting \( \Omega \) to the boundary of the disk in \( \mathcal{O} \) which we chose to construct \( \text{sym}_d(\mathcal{O}) \). We may choose \( c \) in a way to minimise the crossings with \( \eta' \). Then \( \eta' \) crosses \( c \) exactly \( w \) times.

So if we follow the image of \( \eta' \) in \( \text{sym}_d(\mathcal{O}) \) starting from a chosen lift of the crossing point \( Q \), it will reach another lift of \( Q \) in the \( w \)-th copy of the fundamental domain, counting clockwise from the copy where \( Q \) is. Since \( w < d \), these two lifts are in different regions so the lifts of the starting segment and of the ending segment of \( \eta' \) belong to different strands in \( \text{sym}_d(\mathcal{O}) \). In particular, the lifts of \( \eta' \) do not violate condition (5) of Definition 2.1.

An analogous argument applied to the closed subcurve associated to two strands crossing in two points (as in condition (4) of Definition 2.6) shows that condition (4) must hold as well. We conclude that \( \text{sym}_d(\mathcal{O}) \) is a Postnikov diagram, which is also invariant under rotation by \( \frac{\pi}{d} \) by construction.

Now to prove claim (2). First, conditions (1)–(5) in Definition 2.6 follow each from the corresponding condition in Definition 2.1. The inequality of Definition 2.12 follows from the (converse of the argument we used for claim (1): the points in \( \mathcal{P} \) mapping down to a self-intersection in \( \mathcal{P}/s \) must be distinct since \( \mathcal{P} \) is a Postnikov diagram, and so the order \( s \) is large enough. The same holds for two strands crossing in two points, and so \( \mathcal{P}/s \) is an orbifold diagram.

Claim (3) is clear by definition of the operations \( \text{sym}_d \) and \( /s \).

\[ \square \]

3. LABELS ON ORBIFOLD DIAGRAMS

We will now explain how to associate equivalence classes of subsets of \( \{1, \ldots, n\} \) to alternating regions of an orbifold diagram, in a way that corresponds to the construction for Postnikov diagrams from [Pos06].

Let \( \mathcal{O} \) be an orbifold diagram of order \( d \) and of type \( \tau \in S_n \). To it we associate the \( d \)-symmetric Postnikov diagram \( \text{sym}_d(\mathcal{O}) \) as explained before. The latter has \( n = nd \) marked points on the boundary and has type \( \sigma \) for some \( \sigma \) depending on \( \tau \) and \( \mathcal{O} \). For Postnikov diagrams, the rule in [Pos06] can be used to assign a \( k \)-element subset of \( \{1, \ldots, n\} \) to certain regions delimited by the strands (for a certain \( k \) depending on \( \sigma \)). We recall this construction here.

First observe that the complement of the strands of \( \text{sym}_d(\mathcal{O}) \) in the disk is a disjoint union of topological disks, which can each be of one of three kinds. There are \textit{boundary regions}, whose boundary contains a segment (of positive length) of the boundary of the disk, and there are \textit{cyclical} and \textit{alternating} regions, depending on whether the strands adjacent to them give their boundary a cyclic orientation or not. The strands adjacent to the boundary regions are alternatingly oriented and so we count these regions as alternating regions. We will assign to each alternating region a label, which is a subset of \( \{1, \ldots, n\} \).

We do this as follows: every strand divides the disk into two pieces, one on its left and one on its right (when following the strand in its orientation). A number \( i \) is part of the label of an alternating region if and only if the region is in the left piece determined by the strand starting at vertex \( i \). This procedure assigns a subset of some constant cardinality to every boundary and every alternating region as when we move from one alternating region to a neighbouring alternating region we always exchange one label for another one. If the Postnikov diagram is Grassmannian of type \( (k, n) \), then this cardinality is equal to \( k \).

Examples of labels on (symmetric) Postnikov diagrams are on the left hand side of Figure 10 and on the left of Figure 11.

If the Postnikov diagram is \( d \)-symmetric, then the labels of two regions related by rotation by \( \frac{\pi}{d} \) differ by adding \( n_0 = n/d \) (addition on sets is meant pointwise). We use the labels of \( \text{sym}_d(\mathcal{O}) \) to associate labels to the alternating regions of \( \mathcal{O} \) by taking equivalence classes of sets of labels under adding \( n_0 \) pointwise (that is, \( \{i_1, \ldots, i_k\} \sim_{n_0} \{h_1, \ldots, h_k\} \) if there is \( j \) such that \( \{i_1 + jn_0, \ldots, i_k + jn_0\} = \{h_1, \ldots, h_k\} \)).

We use square brackets to denote the equivalence classes of sets of labels: \( [i_1, \ldots, i_k]_{n_0} \), for the set \( \{i_1 + jn_0, i_2 + jn_0, \ldots, i_k + jn_0\} \) with \( 1 \leq j \leq d \). Every alternating region of \( \mathcal{O} \) corresponds to \( d \) different alternating regions of \( \text{sym}_d(\mathcal{O}) \) in general (see Remark 3.2) and as such to an equivalence class \( [i_1, \ldots, i_k]_{n_0} \) of labels. We assign this equivalence class to the alternating region, and do this for all alternating regions of \( \mathcal{O} \).

**Definition 3.1.** Let \( \mathcal{O} \) be an orbifold diagram with \( n_0 \) boundary points. Let \( \mathcal{I} \) be the collection of labels of alternating regions of \( \text{sym}_d(\mathcal{O}) \) and let \( \sim_{n_0} \) be the equivalence relation on \( \mathcal{I} \) described above. We define \( \mathcal{I}_\mathcal{O} = \mathcal{I}/\sim_{n_0} \). By the previous discussion, \( \mathcal{I}_\mathcal{O} \) is the set of labels attached to the alternating regions of \( \mathcal{O} \).

**Remark 3.2.** The equivalence classes \( [i_1, \ldots, i_k]_{n_0} \) usually contain \( d \) elements, corresponding to the \( d \) different regions of \( \text{sym}_\mathcal{O} \) mapping down to a given region of \( \mathcal{O} \). A possible exception is the central region.
of $O$, in case it happens to be alternating: its label is a single subset which is invariant under adding $n_0$ to its elements. In this case we have $[i_1, \ldots, i_k]_{n_0} = \{\{i_1, \ldots, i_k\}\}$.

We now give a way to obtain the labels directly from the orbifold diagram, without going through the associated symmetric Postnikov diagram. We illustrate this algorithm in Examples 3.6, 3.7 and 3.8.

Algorithm 3.3. Step 1: Let $O$ be an orbifold diagram of order $d$ on a disk with $n_0$ marked points. Let $n = dn_0$. Draw a curve $\gamma$ from the orbifold point $\Omega$ to the boundary of the disk which ends between $n_0$ and 1 (see Remark 3.4 (1)) such that $\gamma$ crosses the strands $\gamma_i$ transversally and never goes through a crossing of two strands.

Step 2: The curve $\gamma$ divides (some of) the strands into different connected components which we call segments. We now label these different segments as follows. The strand $\gamma_i$ gets the label $i$ from its starting point to the first intersection with $\gamma$. If $\gamma_i$ leaves $i$ clockwise (i.e. when leaving $i$, it appears to follow the boundary in a clockwise way and the orbifold point is to the right of $\gamma_i$ when it crosses $\gamma$), we subtract $n_0$ from the label, reducing integers modulo $n$. If $\gamma_i$ leaves $i$ counterclockwise, we add $n_0$ to the label, reducing modulo $n$. The segment between the first crossing and the second crossing is then $i \mp n_0$ accordingly. We iterate this until all segments of each $\gamma_i$ are labeled. The labels on the segments of $\gamma_i$ are in $\{1, 2, \ldots, n\}$ since we reduce modulo $n$.

Step 3: Every strand divides the surface into two regions, one on its left and one of its right (when following the strand in its orientation). Furthermore, the complement of all strands is a union of faces, one of them containing the orbifold point, where the boundary of each face is formed by parts of the strands and where each face is either cyclical or alternating. To every alternating region which is not incident with the curve $\gamma$, we associate the label $i + mn_0$ if the alternating region is to the left of the strand segment with label $i + mn_0$ (for some $m \in \mathbb{Z}$).

Step 4: Observe that the alternating regions through which $\gamma$ goes are cut in two if we open the disc $\Sigma$ along $\gamma$. We only associate labels to the region which is counterclockwise from $\gamma$ (see Remark 3.4(2) below) as in Step 3: such an alternating region gets label $i + mn_0$ if it is to the left of the strand segment with label $i + mn_0$ (for some $m \in \mathbb{Z}$).

Step 5: “Add missing labels”: After steps 3 and 4, every alternating region has a certain number of labels. This number is constant as whenever we go from one alternating region to a neighbouring alternating region, we cross exactly two strands, one in each direction, so one label gets added and one removed, keeping the number of labels constant. However, certain elements of $\{1, 2, \ldots, n\}$ do not appear as segment labels (Step 2). Let $j$ be such a label and let $j_0$ be its reduction modulo $n_0$. If the orbifold point $\Omega$ is to the left of strand $\gamma_j$, we associate the label $j$ to every alternating region of $O$. If not, the label $j$ does not appear in any of the regions.

Remark 3.4. (1) The curve $\gamma$ breaks $O$ open so that it can be viewed to be a copy of the fundamental domain of $\text{sym}_d(O)$, with marked points $i, i+1, \ldots, i+n_0-1$ along the boundary (for some $i \in \{1, \ldots, dn_0\}$). It is important that $\gamma$ links the orbifold point $\Omega$ with the boundary segment between $n_0$ and 1, in order for the algorithm to agree with Definition 3.1 without further adjustments.

(2) Note that the collection of the labels on all the segments of the strands $\gamma_i$ is multiplicity-free. In general, it is a proper subset of $\{1, 2, \ldots, n\}$.

(3) Consider an alternating region which is “cut” by $\gamma$. Associate labels to the two halves of this region (under the cut by $\gamma$) according to steps 4 and 5. Let $\{i_1, \ldots, i_r\}$ be the labels of the region clockwise from $\gamma$. Then the labels of the other half are $\{i_1 + n_0, \ldots, i_r + n_0\}$.

Comparing the above construction with the definition of labels for orbifold diagrams, we get:

Lemma 3.5. The set of labels for $O$ obtained through Algorithm 3.3 is a system of representatives for $I_O$.

We illustrate the algorithm on the three running examples to show how we associate labels to orbifold diagrams.

Example 3.6. In Figure 8, we apply Algorithm 3.3 to the orbifold diagram of Example 2.13 (2). Recall that $d = 5$ and $n = 10$. The labels to consider in Step 5 are 3, 5, 10. Only 10 satisfies the condition of Step 5 and will get added to all alternating regions.
Example 3.7. In Figure 9, we apply the Algorithm 3.3 to Example 2.13 (1) with $d = 3, n = 9$. The labels to consider in Step 5 are 5, 7, 9. Both 7 and 9 satisfy the condition and will get added to all alternating regions.

Example 3.8. We consider the orbifold diagram $\mathcal{O}$ of order 3 from Example 2.11 and want to determine its labels. In this example we have an alternating region around the orbifold point of order 3. We are going to use Definition 3.1. On the left hand in Figure 10 we have the labels for the Postnikov diagram $\text{sym}_3(\mathcal{O})$, the dashed lines indicate three fundamental regions for the action, namely the rotation by $\frac{2\pi}{3}$. For each alternating region of the diagram on the left in Figure 10, we assign an equivalence class of 3-element subsets of $\{1, 2, \ldots, 9\}$ by considering a representative given by the label associated with the fundamental region containing the vertices $\{2, 3, 4\}$ of $\text{sym}_3(\mathcal{O})$ on the right of the same Figure. Note that all but the region containing the orbifold point have an equivalence class with three elements, one for each copy of the fundamental region. The region containing the orbifold point has an equivalence class with just one element because the corresponding region in $\text{sym}_3(\mathcal{O})$ is fixed by the action.

4. Quivers with potentials

Now we shall define a quiver with potential (QP for short) associated to an orbifold diagram, in order to compare it with the one associated to its cover as in [BKM16, Section 3].

Definition 4.1. Let $\mathcal{P}$ be a Postnikov diagram. We associate to it a quiver with potential $(Q_\mathcal{P}, W_\mathcal{P})$ as follows. The vertices of $Q_\mathcal{P}$ are given by the alternating regions of $\mathcal{P}$ (recall that we treat boundary regions as alternating). For any two alternating regions sharing a crossing, there is an arrow in $Q_\mathcal{P}$ going through that crossing following the orientation of the strands. Observe that $Q_\mathcal{P}$ is naturally a quiver with faces, with fundamental cycles corresponding to cyclical regions of $\mathcal{P}$. The potential $W_\mathcal{P}$ is defined as the sum of these cycles, with signs depending on their orientations.
Figure 10. The first figure shows the labels of \( \text{sym}_3(\mathcal{O}) \), the second figure shows the equivalence classes of the labels for \( \mathcal{O} \) under the equivalence relation \( \sim_3 \).  

Figure 11. The quiver \( Q_P \) for \( \mathcal{P} = \text{sym}_3(\mathcal{O}) \) from Example 2.9, straightened on the right.

**Example 4.2.** In Figure 11, we have the quiver \( Q_P \) for the Postnikov diagram (with labels) from Figure 2. On the right, the quiver is drawn with straight arrows. The potential \( W_P \) is  

\[
\sum_{i=1}^{7} \text{sgn}(c_i)c_i = c_1 - c_2 + c_3 - c_4 + c_5 - c_6 + c_7,
\]

for \( c_i \) the fundamental cycle of the face indicated by \( c_i \), taken with + if and only if \( c_i \) is counterclockwise.

The quiver \( Q_P \) is called a dimer model with boundary in [BKM16]. We recall the definition of the (frozen) Jacobian algebra associated to a quiver with potential:

**Definition 4.3.** Let \((Q_P, W_P)\) be the quiver with potential associated to the Postnikov diagram \( \mathcal{P} \). The **frozen Jacobian algebra associated to the QP** \((Q_P, W_P)\) is the completed path algebra of \( Q_P \) modulo the closure of the relations given by the cyclic derivatives of the potential with respect to internal arrows (arrows incident with two faces): Let \( \alpha \) be internal and let \( c_1 \) and \( c_2 \) be the two fundamental cycles containing \( \alpha \), with \( \text{sgn} c_1 = + \), \( \text{sgn} c_2 = - \). We write \( c_i = \alpha c_i \) for \( i = 1, 2 \). Then \( \partial_\alpha W_P = c_1 - c_2 \). In other words, for any internal arrow \( \alpha \), the two paths completing \( \alpha \) to a fundamental cycle agree. For example, in Figure 11, the arrow 14679 \( \to \) 12467 induces as a relation that the path of length 2 from 12467 to 14679 is equal to the path of length 3 from 12467 to 14679.

**Definition 4.4.** Now assume that \( \mathcal{P} \) is reduced, i.e. no reduction moves such as in Figure 1 are possible. Then we define the algebra \( A(\mathcal{P}) \) of \( \mathcal{P} \) as the (completed) frozen Jacobian algebra of \((Q_P, W_P)\), where the frozen vertices correspond to the boundary regions. If \( e \) is the idempotent corresponding to the vertices of the boundary regions, we also define the boundary algebra \( B(\mathcal{P}) \) of \( \mathcal{P} \) to be the idempotent subalgebra \( eA(\mathcal{P})e \).
We will give an analogous definition of quiver with potential for orbifold diagrams, in such a way that the frozen Jacobian algebras are related to each other by a skew group algebra construction. This requires some work.

**Definition 4.5.** Let $\mathcal{O}$ be an orbifold diagram of order $d$. We associate to it a quiver $Q_{\mathcal{O}}$ as follows. The vertices of $Q_{\mathcal{O}}$ are given by the alternating regions of $\mathcal{O}$ (including the regions on the boundary). If the orbifold point $\Omega$ is contained in an alternating region, we associate to that region $d$ vertices $v_1, \ldots, v_d$ of $Q_{\mathcal{O}}$. We imagine the $v_i$ as lying on a line orthogonal to the disk above the orbifold point. For any two vertices which are separated by a crossing of oriented strands, there is an arrow in $Q_{\mathcal{O}}$ going through that crossing following the orientation of the strands. In the case of vertices $v_1, \ldots, v_d$ (if present), we draw arrows between each of them and all the neighbouring regions but no arrows between these vertices.

In case the region containing $\Omega$ is alternating, with an even number $r \geq 2$ of arrows incident with it, then each of the vertices $v_i$ has $r$ fundamental cycles incident with it.

The quiver $Q_{\mathcal{O}}$ is also naturally a quiver with faces: Its fundamental cycles correspond to cyclical regions in $\mathcal{O}$ which do not involve the orbifold point, together with $d$ copies of the $r$ cycles corresponding to cyclical regions adjacent to the central region containing $\Omega$, if this region is alternating. Seen as a CW-complex, this quiver with faces consists in this case of an annulus where the boundaries are given by non-oriented cycles, together with $d$ disks. These disks are all isomorphic as quivers with faces and their boundary cycle (which is in general not oriented) is identical to the inner boundary cycle of the annulus. These boundary cycles are identified with the inner boundary of the annulus, i.e. the $d$ disks are all glued along one of the boundary components of this annulus, see [GP19, Proposition 7.7]. If the region containing $\Omega$ is cyclical then $Q_{\mathcal{O}}$, as quiver with faces, is a tiling of the disk.

In what follows, if $\Omega$ belongs to an alternating region, we write $c_i^{(1)}, \ldots, c_i^{(r)}$ for the $r$ fundamental cycles in $Q_{\mathcal{O}}$ through $v_i$, for $i = 1, \ldots, d$. The labeling is done in a way such that the $c_i^{(r)}$ is the unique cyclical region adjacent to the central alternating region and intersecting the curve $\gamma$.

Note that all the fundamental cycles come with an orientation and hence with a sign: We set $\text{sgn}(c)$ to be 1 if $c$ is a counterclockwise fundamental cycle and $-1$ if $c$ is clockwise. Then we can define a potential for the quiver $Q_{\mathcal{O}}$.

**Definition 4.6.** Let $\mathcal{O}$ be an orbifold diagram of order $d$ and let $Q_{\mathcal{O}}$ be its quiver. Let $\mathcal{C}$ be the set of the fundamental cycles of $Q_{\mathcal{O}}$. We define a potential $W_{\mathcal{O}}$ on $Q_{\mathcal{O}}$ as follows.

- Assume that the orbifold point $\Omega$ lies in a cyclical region and let $c$ be the corresponding fundamental cycle. We set
  \[
  W_{\mathcal{O}} = \frac{1}{d} \text{sgn}(c) c^d + \sum_{c' \in \mathcal{C} \setminus \{c\}} \text{sgn}(c') c'.
  \]

- Assume that $\Omega$ lies in an alternating region and let $\mathcal{C}'$ the set of all the $c_i^{(j)}$. Fix a primitive $d$-th root of unity $\zeta$. We set
  \[
  W_{\mathcal{O}} = \sum_{c \in \mathcal{C} \setminus \mathcal{C}'} \text{sgn}(c)c + \sum_{j \neq r} \sum_{i=1}^{d} \text{sgn}(c_i^{(j)}) c_i^{(j)} + \sum_{i=1}^{d} \zeta^i \text{sgn}(c_i^{(r)}) c_i^{(r)}.
  \]

**Remark 4.7.** The above definition of $W_{\mathcal{O}}$ depends on the choice of $\zeta$. However, Theorem 6.23 shows that the frozen Jacobian algebras corresponding to different choices are isomorphic.

**Remark 4.8.** The potential $W_{\mathcal{O}}$ of Definition 4.6 is equal, for suitable choices (see the proof of Proposition 6.1), to the potential $W_{\mathcal{G}}$ of [GP19, Notation 3.18] divided by $d$. It is also equal to the potential $W_{\mathcal{G}}$ of [GPP19, Definition 5.3].

**Definition 4.9.** For an orbifold diagram $\mathcal{O}$, define the algebra $A(\mathcal{O})$ of $\mathcal{O}$ as the frozen Jacobian algebra of $(Q_{\mathcal{O}}, W_{\mathcal{O}})$, with frozen vertices the boundary vertices. If $c$ is the idempotent corresponding to the boundary vertices, we define the boundary algebra $B(\mathcal{O})$ of $\mathcal{O}$ to be the algebra $B(\mathcal{O}) = cA(\mathcal{O})c$.

Note that whenever for $\mathcal{O}$, the orbifold point $\Omega$ is contained in a cyclic region, we have a new type of terms in the relations for $A(\mathcal{O})$: In this case, the cycle (or loop) appears as term $c^d$ in the potential. Taking derivatives with respect to arrows of this cycle (with respect to the arrow of the loop) gives a $d$-fold term in the relations for $A(\mathcal{O})$ (with this $d$ cancelling out the $\frac{1}{d}$ coefficient). For the quiver with potential in Figure 12, taking the derivative with respect to the loop arrow $c$ gives $c_1' = c_2'$, where $c_1'$ is the path $[14679]_3 \to [14789]_3 \to [12479]_3$. 

Example 4.10. We illustrate Definitions 4.5 and 4.6 on the orbifold diagram $\mathcal{O}_1$ of order 3 from Example 2.13 (1) with labels in Example 3.7 and on the orbifold diagram $\mathcal{O}_2$ from Example 2.13 (2) with labels in Example 3.6. The quivers $Q_{\mathcal{O}_1}$ and $Q_{\mathcal{O}_2}$ are depicted in Figure 12 and Figure 13, respectively.

$W_{\mathcal{O}_1} = -c_1 + c_2 + \frac{1}{3}c_3,$

$W_{\mathcal{O}_2} = -c_1 + c_2 + c_3 - c_4 + \frac{1}{5}c_5.$

Figure 12. The quiver $Q_{\mathcal{O}_1}$ associated to the orbifold diagram of Examples 2.13(1).

Figure 13. The quiver $Q_{\mathcal{O}_2}$ associated to the orbifold diagram of Examples 2.13(2).

Figure 14. The quiver $Q_{\mathcal{O}}$ associated to an orbifold diagram $\mathcal{O}$ of order 3 with the orbifold point inside an alternating region and the fundamental cycles $c_i$ far away from the orbifold point.
**Example 4.11.** Let us consider the quiver with potential for the orbifold diagram $\mathcal{O}$ given in Example 3.8. Recall that this example is particularly interesting because it has an alternating region containing the orbifold point. We are going to follow Definition 4.5. The quiver $Q_\mathcal{O}$ is depicted in Figure 14. Note that on the right of Figure 10 the alternating region containing the orbifold point got the label $[147]_3$. Following Definition 4.5, the label $[147]_3$ yields three vertices called $v_1$, $v_2$, and $v_3$ on $Q_\mathcal{O}$, see Figure 14. Since the alternating region containing $\Omega$ is given by 2 arrows, we have two cyclic regions around this region /with label $[147]$. One is a triangle given by $\{[124]_3, [127]_3, [147]_3\}$, the other one is a quadrilateral given by $\{[127]_3, [147]_3, [124]_3, [179]_3\}$. We write $c_i^3$ ($i = 1, 2, 3$) to denote the three fundamental cycles arising from the triangle at $[147]_3$ and $c_i^2$ for the three fundamental cycles arising from the quadrilateral. These six faces are illustrated in Figure 15 by different shadings. The labeling of the other faces is given in Figure 14. We thus have the potential

$$W_{\mathcal{O}} = +c_1 - c_2 + c_3 - c_4 + c_1^{(1)} + c_2^{(1)} + c_3^{(1)} - \zeta c_1^{(2)} - \zeta^2 c_2^{(2)} - c_3^{(2)},$$

where $\zeta$ is a primitive third root of the unity.

**Figure 15.** The fundamental cycles around the orbifold point on $Q_\mathcal{O}$.  

5. **Skew group algebras from orbifold diagrams**

In this section we recall the notion of a skew group algebra and prove properties which we will need later. We want to relate the algebras $A(\mathcal{O})$ and $B(\mathcal{O})$ of an orbifold diagram $\mathcal{O}$ with the algebras $A(\text{sym}_d(\mathcal{O}))$ and $B(\text{sym}_d(\mathcal{O}))$ of the associated symmetric Postnikov diagram. In particular, we want to describe endomorphism algebras (see Lemma 5.7 and Lemma 5.3). This will be a key ingredient for Section 6 where we study the associated module categories.

**Definition 5.1.** Let $S$ be an algebra with an action of a finite group $G$ by automorphisms. The skew group algebra $S * G$ is $S \otimes_\mathbb{C} CG$ as a vector space, with multiplication linearly induced by

$$(s \otimes g)(t \otimes h) = sg(t) \otimes gh$$

(where $s, t \in S$, $g, h \in G$).

The group $G$ acts on the category $\text{mod}(S)$ (left modules) by twists, that is $g(L) = ^gL$ which is $L$ as a set, with $S$-action given by $s \cdot ^gL = g(s)L$, noting that for all $g, h \in G$, we have $^g(\cdot hL) = ^{hg}L$. This gives an autofunctor of $\text{mod}(S)$ by letting $G$ act trivially on morphisms. To simplify the notation, we will write morphisms as $f$ instead of $^g f$.

There is an induction functor $F$ from $\text{mod} S$ to $\text{mod}(S * G)$ sending $M$ to $FM := (S * G) \otimes_S M$.

The category of $G$-equivariant $S$-modules $\text{mod}(S)^G$ is defined to have as objects the pairs $(L, (\varphi_g)_{g \in G})$, where $L$ is an object of $\text{mod}(S)$ and where the $\varphi_g : L \to ^gL$ are isomorphisms satisfying the following:

1. $\varphi_{hg} = \varphi_h \circ \varphi_g$,
2. $\varphi_1 = \text{id}_L$.

Morphisms in $\text{mod}(S)^G$ are morphisms of $S$-modules which intertwine the $\varphi_g$. Precisely, if $(L, (\varphi_g)_{g \in G})$ and $(N, (\psi_g)_{g \in G})$ are in $\text{mod}(S)^G$, then a map $f : L \to N$ of $S$-modules is a morphism in $\text{mod}(S)^G$ if
there is a commutative diagram

\[
\begin{array}{ccc}
L & \xrightarrow{f} & N \\
\varphi_g & \downarrow & \psi_g \\
gL & \xrightarrow{g} & gN
\end{array}
\]

for every \( g \in G \).

In what follows, we will use the fact that the category of finitely generated \( S \ast G \)-modules is equivalent to the category \( \text{mod}(S) \ast G \), as an \( S \ast G \)-module can be viewed as an \( S \)-module with a compatible \( G \)-action.

From now on, let us assume that \( G \) is of finite order \( d \). We will use the skew-group construction for \( G \) and the algebras associated to orbifold diagrams (of order \( d \)). On one hand, we will have modules which are invariant under the group action and on the other hand modules, which are permuted by the elements of \( G \). In Section 6, we will use the effect of the \( F \) on modules which are built up from these two types, i.e. we will need to study the functor \( F \) on a direct sum \( M_0 \oplus M \) where \( M_0 \) is invariant under the group action and where \( M \) is a sum of isomorphic summands for each group element (see Lemma 6.14).

Let \( M_0 \in \text{mod}(S) \) be a module such that \( gM_0 = M_0 \) for all \( g \in G \).

Then

\[
FM_0 = \left( \bigoplus_{g \in G} M_0, (\varphi_g)_h \right) = \left( \bigoplus_{\sigma \in G^*} M_0, (\lambda_h)_h \right) = \bigoplus_{\sigma \in G^*} (M_0, (\sigma(h) \text{id})_h),
\]

where \( (\lambda_h)_{\sigma, \sigma} = \sigma(h) \text{id}_{M_0} \) and the other entries of \( \lambda_h \) are zero. This is because the subset

\[
\left\{ x \in \bigoplus_{g \in G} M_0 \mid h(x) = \sigma(h)x \right\} \subseteq \bigoplus_{g \in G} M_0
\]

is isomorphic to \( M_0 \) as an \( S \)-module (intuitively, we are decomposing the regular representation into the \( G \)-irreducible characters of \( G \)).

Let \( M_1 \in \text{mod}(S) \) be any module. Define \( M_g = gM_1 \) for every \( g \in G \), and \( M = \bigoplus_{g \in G} M_g \). Then define \( \varphi_g : M \to gM \) to be the canonical isomorphism that permutes the summands, i.e. \( \varphi_g(M_h) = gM_{g^{-1}h} \). This makes \( (M, (\varphi_g))_{g \in G} \) an object in \( \text{mod}(S) \ast G \). As a module over \( S \ast G \), it is \( M \) with \( b \otimes g \) acting by \( \varphi_g \circ b \circ g^{-1} \). We will just write \( M \) for this object of \( \text{mod}(S) \ast G \) as well as for the \( S \)-module \( M \).

**Remark 5.2.** Observe that we really mean \( M \) as an \( (S \ast G) \)-module, and not \( FM \). Indeed, we have \( FM \cong M^{S \ast d} \), and in fact \( M = FM_1 \) naturally. As vector spaces, \( M = \mathbb{C}G \otimes \mathbb{C} M_1 \).

**Lemma 5.3.** With the notation as above, there is an algebra isomorphism

\[
\text{End}_S(M_0 \oplus M) \ast G \cong \text{End}_{S \ast G}(FM_0 \oplus FM)
\]

which maps any \( f \otimes g \) to

\[
FM_0 \otimes M \quad \rightarrow \quad FM_0 \otimes M \\
(s \otimes h) \otimes m \quad \mapsto \quad (s \otimes hg^{-1}) \otimes f(\varphi_g(m))
\]

**Proof.** We will show that this is a composition of two vector space isomorphisms \( \theta_1 \) and \( \theta_2 \) which we now define. First consider

\[
\theta_1 : \text{End}_S(M_0 \oplus M) \ast G \rightarrow \text{Hom}_S(M_0 \oplus M, FM_0 \oplus M).
\]

The map \( \theta_1 \) can be obtained as follows: we send \( f \otimes g \in \text{End}_S(M_0 \oplus M) \otimes \mathbb{C}G \) to the homomorphism

\[
M_0 \oplus M \quad \rightarrow \quad FM_0 \oplus M \\
m \quad \mapsto \quad (1 \otimes g^{-1}) \otimes f(\varphi_g(m)).
\]

in \( \text{Hom}_S(M_0 \oplus M, FM_0 \oplus M) \). Then consider

\[
\theta_2 : \text{Hom}_S(M_0 \oplus M, FM_0 \oplus M) \rightarrow \text{End}_{S \ast G}(FM_0 \oplus M)
\]

This is the adjunction isomorphism of vector spaces which maps any \( f \in \text{Hom}_S(M_0 \oplus M, FM_0 \oplus M) \) to

\[
FM_0 \otimes M \quad \rightarrow \quad FM_0 \otimes M \\
(s \otimes g) \otimes m \quad \mapsto \quad (s \otimes g) \cdot f(m)
\]

The composition \( \theta_2 \circ \theta_1 \) sends \( f \otimes g \) to \( (s \otimes h) \otimes m \mapsto (s \otimes hg^{-1}) \otimes f(\varphi_g(m)) \). Furthermore, the fact that the composition is multiplicative is a direct check. So \( \theta_2 \circ \theta_1 \) is an algebra homomorphism.

Now we introduce two homomorphisms of \( S \ast G \)-modules.
Definition 5.4. (1) Let \( i : \text{FM}_0 \oplus M \to \text{FM}_0 \oplus \text{FM} \) be the following map:
\[
(m_0, m) \in \text{FM}_0 \oplus M \mapsto \left( m_0, \frac{1}{|G|} \sum_{g \in G} (1 \otimes g) \otimes \varphi^{-1}(m) \right)
\]

(2) Let \( p : \text{FM}_0 \oplus \text{FM} \to \text{FM}_0 \oplus M \) be the following map
\[
(m_0, \sum_{g \in G} (s_g \otimes g) \otimes m_g) \mapsto \left( m_0, \sum_{g \in G} s_g \cdot \varphi_g(m_g) \right)
\]

The proof of the following follows immediately from the definition.

Lemma 5.5. The maps \( i \) and \( p \) are homomorphisms of \( S \ast G \)-modules. Furthermore, their composition \( p \circ i \) is the identity homomorphism.

Next we set \( e \) to be the preimage under \( \theta_2 \circ \theta_1 \) of the element \( i \circ p \) of \( \text{End}_{S \ast G}(\text{FM}_0 \oplus \text{FM}) \). This is an idempotent in \( \text{End}_S(\text{M}_0 \oplus M) \ast G \) because \( i \circ p \) is an idempotent of \( \text{End}_{S \ast G}(\text{FM}_0 \oplus \text{FM}) \).

Lemma 5.6. There is an algebra isomorphism \( \text{End}_{S \ast G}(\text{FM}_0 \oplus M) \cong e \cdot (\text{End}_S(\text{M}_0 \oplus M) \ast G) \cdot e \).

Proof. This follows using the maps
\[
\begin{align*}
\beta_1 : \quad & \text{End}_{S \ast G}(\text{FM}_0 \oplus \text{FM}) \quad \to \quad \text{End}_{S \ast G}(\text{FM}_0 \oplus M) \\
& f \quad \mapsto \quad p \circ f \circ i \\
\beta_2 : \quad & \text{End}_{S \ast G}(\text{FM}_0 \oplus M) \quad \to \quad \text{End}_{S \ast G}(\text{FM}_0 \oplus \text{FM}) \\
& f' \quad \mapsto \quad i \circ f' \circ p
\end{align*}
\]
with \((\beta_1 \circ \beta_2)(f') = f'\) and \((\beta_2 \circ \beta_1)(f) = i \circ p \circ f \circ i \circ p\) and since \( \text{End}_S(M_0 \oplus M) \ast G \cong \text{End}_{S \ast G}(\text{FM}_0 \oplus \text{FM}) \) by Lemma 5.3.

Then since \( FM \) is isomorphic to \( M^{[G]} \) as a \( S \ast G \)-module, the algebras \( \text{End}_{S \ast G}(\text{FM}_0 \oplus M) \) and \( \text{End}_G(M_0 \oplus M) \ast G \) are Morita equivalent:

Lemma 5.7. With the notation as above, we have \( \text{End}_{S \ast G}(\text{FM}_0 \oplus M) \sim \text{End}_S(M_0 \oplus M) \ast G \).

6. Characterising the algebras arising from orbifold diagrams

In this section we combine the results of the previous sections to characterise the algebras \( A(\mathcal{O}) \) and \( B(\mathcal{O}) \). From now on, we assume that \( \mathcal{O} \) is a reduced orbifold diagram on a disk with \( n_0 \) marked points and that its cover \( \text{sym}_d(\mathcal{O}) \) is a (reduced) Postnikov diagram on a disk with \( n = n_0 \cdot \text{d} \) marked points. By Proposition 2.14, this is the case as soon as \( \text{d} > 2 \). There are examples of orbifold diagrams of order \( 2 \) where \( \text{sym}_2(\mathcal{O}) \) is also a Postnikov diagram and the results in this section hold in this case.

Let \( \mathcal{P} \) be a \( d \)-symmetric Postnikov diagram. Let \( G \) be the cyclic group generated by clockwise rotation by \( \frac{2\pi}{\text{d}} \). This group acts on both \( A(\mathcal{P}) \) and \( B(\mathcal{P}) \) by automorphisms in a natural way, and exactly this group and its action that we fix when we take skew group algebras. Before restricting to the Grassmannian setting, we present a general result.

We will use the construction of the quiver with potential of a skew group algebra given in [GP19]. For convenience of the reader, we summarize here some points about this construction. If \((Q, W)\) is a QP and \( G \) is a finite group acting on \( Q \) fixing \( W \), it is known by the work of Le Meur, [LM20], that the skew group algebra of the Jacobian algebra of \((Q, W)\) is Morita equivalent to the Jacobian algebra of a new QP \((Q_G, W_G)\). (We will use \( \sim \) below to denote Morita equivalence). Under certain assumptions which are satisfied in the case of a symmetric Postnikov diagram with \( G \) acting by rotations, one can describe \((Q_G, W_G)\) explicitly. The quiver \( Q_G \) was constructed in [RR85], and the potential \( W_G \) is defined in [GP19, Notation 3.18] after making certain choices, notably: a set of representatives of vertices of \( Q \), and a suitable set of representatives of cycles appearing in \( W \). The potential \( W_G \) depends on these choices (and on the choice of a primitive root of unity), but the resulting Jacobian algebras are isomorphic.

Proposition 6.1. Let \( \mathcal{O} \) be an orbifold diagram of order \( d \). Then we have the Morita equivalences
\[
A(\mathcal{O}) \sim A(\text{sym}_d(\mathcal{O})) \ast G
\]
and
\[
B(\mathcal{O}) \sim B(\text{sym}_d(\mathcal{O})) \ast G.
\]
Proof. We will use Theorem 3.20 of [GP19], with $\Lambda$ being $A(\text{sym}_d(O))$. We remark this theorem still works if we replace the usual definition of the Jacobian ideal by any ideal generated by cyclic derivatives with respect to arrows (see Definition 4.3) provided that these arrows are closed under the $G$-action. In particular, the statement immediately extends to the case of frozen arrows, which we are considering in our definition of $A(O)$. In our case, the frozen arrows are the boundary arrows, which indeed form a set closed under the $G$-action.

Moreover, the $G$-orbits of the boundary arrows for $A(\text{sym}_d(O))$ correspond exactly (in the sense of [GP19, Notation 3.13]) to the boundary arrows of $A(O)$. It follows that even in our case, it is enough to show that the QP $(Q_G, W_G)$ of [GP19] is equal to $(Q_O, W_O)$, if we make appropriate choices. The fact that $Q_G = Q_O$ is clear, as the two constructions both agree with the general construction presented in [RR85, Section 2]. This is also illustrated in Examples 8.1 and 8.3 of [GP19].

If the central region is cyclical, we are in the special case where $G$ acts freely on the whole quiver $Q$ of $\Lambda = A(\text{sym}_d(O))$ (and hence on $\Lambda$), which means that $\Lambda * G$ is Morita equivalent to the quotient $\Lambda/G$. In particular, the potential $W_O$ we have defined in this case makes $A(O)$ isomorphic to this quotient and we are done.

It remains to check that the potential $W_O$ equals the potential $W_G$ of [GP19, Notation 3.18] (for appropriate choices) in the case where the central region is alternating. Following [GP19, §3.2], we choose a set $E$ of representatives of vertices of $Q$. In order to get the simple formulas we gave for $W_O$, we should be careful in how we choose the set $E$. Let us pick a simple curve joining $\Omega$ to the boundary in $O$, draw its $d$ preimages under the quotient in sym$_d(O)$, and consider one of the regions bounded by two consecutive copies, see for example Figure 10. We pick $E$ to consist of exactly the vertices in this region. If the curve cuts an alternating region in two, we pick the part which is clockwise from the two copies of the simple curve and inside this region.

We will now introduce some notation borrowed from [GP19]. Consider a cycle $c$ appearing in $W$, say with a scalar $a(c)$. Then there are two possible cases:

- either $c$ does not go through the central region (and all its vertices have trivial stabiliser),
- or $c$ goes through the central region (and all its vertices except the one corresponding to the central region have trivial stabiliser).

Following [GP19, Notation 3.6], we say that $c$ is of type (i) in the former case and of type (ii) in the latter (we remark that [GP19] treats additional cases which do not appear here). Our construction will associate a summand in $W_G$ to every $G$-orbit of cycles appearing in $W$ (recall that $W$ is indeed $G$-invariant). By possibly applying the $G$-action, we can assume that $c$ is equal to

$$I_0 = g^{t_1+\cdots+t_l}(I_1) \rightarrow g^{t_1+t_1+t_{l-1}}(I_{l-1}) \rightarrow \cdots \rightarrow g^{t_1}(I_1) \rightarrow I_0,$$

where $\alpha_1, \ldots, \alpha_l$ are arrows of $Q$, $t_1, \ldots, t_l$ are integers, and $I_0, \ldots, I_l$ are vertices in $E$. If $c$ is of type (i), this choice is not unique. If $c$ is of type (ii), then we can also assume that $I_1$ is the label of the central region (and then the choice is in fact unique).

Note that each $t_i$ is equal to $-1, 1$ or $0$ according to whether the arrow $\alpha_i$ crosses the cut $\gamma$ of step 1 of Algorithm 3.3 clockwise, counterclockwise or not at all, respectively.

The potential $W_G$ of [GP19, Notation 3.18] is defined to be the sum of the contributions of all $(G$-orbits of) cycles appearing in $W$, as follows.

- If $c$ is of type (i), then (each $\alpha_i \otimes g^{t_i}$ is an arrow of $Q_G$ and) its contribution to $W_G$ is

$$a(c)(\alpha_1 \otimes g^{t_1}) \cdots (\alpha_l \otimes g^{t_l}).$$

- If $c$ is of type (ii), then:

  - by our choice, we have $t_1 = 0$,
  - each $\alpha_i \otimes g^{t_i}$ is an arrow of $Q_G$ for $i \neq 1, 2$,
  - for $\mu = 0, \ldots, d - 1$, both $\alpha_1 \otimes e_\mu$ and $g^{-t_2}(\alpha_2) \otimes e_\mu$ are arrows of $Q_G$, where $e_\mu$ is the element

$$e_\mu = \frac{1}{d} \sum_{i=0}^{d-1} \zeta^{\mu i} g^i,$$

  - the contribution of $c$ to $W_G$ is defined to be

$$\sum_{\mu=0}^{d-1} a(c)\zeta^{-t_2\mu}(\alpha_1 \otimes e_\mu)(g^{-t_2}(\alpha_2) \otimes e_\mu)(\alpha_3 \otimes g^{t_3}) \cdots (\alpha_l \otimes g^{t_l}).$$
The contributions of the cycles of type (i) to both $W_G$ and $W_O$ (where they correspond to $C \setminus C'$) are easily seen to agree, so it remains to check what happens with the cycles going through the middle (those giving rise to the cycles in $C'$).

The region between the two curves we chose on $\text{sym}_d(O)$ contains $\frac{r}{2}$ outgoing and $\frac{r}{2}$ incoming arrows to the central vertex, so that $r-1$ cycles $\tilde{e}$ corresponding to the cycles of type (ii) have $l_2 = 0$. The contribution of these cycles to $W_G$ is then precisely the same as the part of the sum with no roots of unity in our definition of $W_O$. There is exactly one cycle $\tilde{e}$ missing, which has $l_2$ equal to $\pm 1$ depending on whether it is clockwise or not. By possibly choosing $\zeta^{-1}$ instead of $\zeta$, we can make the remaining terms in $W_G$ and $W_O$ be equal, proving the first statement.

The second statement follows directly from the first and [RR85, Lemma 2.2]. \hfill $\Box$

Let us recall a construction of [JKS16]. Let $\Pi_n$ be the complete preprojective algebra of type $A(n-1)$, with vertices $1, 2, \ldots, n$ around the cycle and arrows labeled $x_i : (i-1) \to i$ and $y_i : i \to (i-1)$.

**Definition 6.2** ([JKS16]). Let $B = B(k, n)$ be the quotient of $\Pi_n$ by the closure of the ideal generated by the relations $x^k - y^{n-k}$.

This algebra gives rise to an additive categorification of Scott’s cluster algebra structure of the coordinate ring of the affine cone over the Grassmannian variety of $k$-spaces in $\mathbb{C}^n$, by taking the category $F_{k,n}$ of maximal Cohen-Macaulay modules over $B$. [JKS16]. Furthermore, every Postnikov diagram of type $(k, n)$ gives rise to a cluster-tilting object for this category, [BKM16] and from the boundary of its endomorphism algebra we recover the algebra $B$:

**Proposition 6.3** ([BKM16]). Let $\mathcal{P}$ be a Grassmannian Postnikov diagram of type $(k, n)$. Then $B(\mathcal{P}) \cong B^{op}$.

Recall that $n_0 = n/d$. We define a quotient of $\Pi_{n_0}$ similarly as above. It will give us a basic Morita equivalent version of $B \ast G$.

**Definition 6.4.** Let $B_G = B_G(n_0, k, n)$ be the quotient of $\Pi_{n_0}$ by the ideal generated by the relations $x^{k_0} - y^{n-k_0}$.

The group $G$ acts on $B$ by letting the generator act by the quiver automorphism rotating $i$ to $i + \text{GCD}(n, k)$. Denote this automorphism by $g$.

**Proposition 6.5.** Let $\tilde{e} = e_1 + \cdots + e_{n_0}$ be the idempotent in $B$ corresponding to the first $n_0$ vertices of $\Pi_n$. Then $\tilde{e} \otimes 1$ is a Morita idempotent in $B \ast G$, and there is an isomorphism $B_G \cong (\tilde{e} \otimes 1)B \ast G(\tilde{e} \otimes 1)$ mapping $e_i$ to $e_i \otimes 1$, $x_i$ and $y_i$ to $x_i \otimes 1$ and $y_i \otimes 1$ for $i \neq 1$, $x_1$ to $x_1 \otimes g^{-1}$, and $y_1$ to $y_{n_0+1} \otimes g$.

**Proof.** The first assertion follows from [RR85] since the first $n_0$ vertices form a cross-section of vertices of the quiver of $B$ under the action of $G$. The explicit isomorphism is a direct application of [GPP19, Lemma 4.6], observing that $ya_{n+1} \otimes g = (1 \otimes g)(ya_i \otimes 1)$. \hfill $\Box$

From now on we will freely identify $B_G$ with $(\tilde{e} \otimes 1)B \ast G(\tilde{e} \otimes 1)$ using this isomorphism.

**Corollary 6.6.** Let $n = dn_0$, let $O$ be a Grassmannian orbifold diagram of order $d$ and of type $(k, n)$. Then we have that $B(O) \cong (B_G)^{op}$.

**Proof.** We have $B(O) \sim B(\mathcal{P}) * G \sim B^{op} * G \sim (B_G)^{op}$, and both algebras are basic. \hfill $\Box$

### 6.1 Modules for the skew group algebra $B_G$.

For the rest of the paper, we assume that $O$ is a Grassmannian orbifold diagram of type $(k, n)$ and of order $d$, see Definition 2.12. In particular, $k = n_0 w_+$ for $w_+$ a common winding number of all strands. Thus its universal cover $\mathcal{P} = \text{sym}_d(O)$ is a $d$-symmetric Grassmannian Postnikov diagram of type $(k, n)$. Our goal is to explain the relationship between the boundary algebras $B(\mathcal{P})$ and $B(O)$ of the two diagrams. By the above results (Proposition 6.3 and Corollary 6.6), these algebras are isomorphic to (the opposites of) $B$ and $B_G$ respectively, independently of $O$ and its symmetrized version, so we will focus our attention on the algebras $B$ and $B_G$, for which we have a quiver description.

The algebra $B$ and its singularity category have been thoroughly studied, see for instance [JKS16], [DL16], [BBGE19]. We are interested in carrying out a similar study for $B_G$.

The element $t = \sum_i x_i y_i$ is central in $B$ and in fact, $\text{Z}(B) = \mathbb{C}\langle t \rangle$, [JKS16]. Its image $(\tilde{e} \otimes 1)(t \otimes 1)(\tilde{e} \otimes 1)$ is a central element of $B_G$.

We are interested in special $B$-modules, namely the rank one Cohen-Macaulay $B$-modules. They give rise to cluster-tilting objects in the category $\mathcal{F}_{k,n}$ of maximal Cohen-Macaulay modules over $B$. Furthermore, every object in $\mathcal{F}_{k,n}$ has a filtration by such modules. These modules are constructed as follows.
Definition 6.7. Let $I$ be a $k$-element subset of $\{1, \ldots, n\}$. Let $L_I$ be the $B$-module given as a representation by:

- A copy of $Z(B)$ at every vertex. Call $1_i$ the identity of $Z(B)$ at vertex $i$.
- The arrow $x_i$ maps $1_{i-1}$ to $1_i$, if $i \in I$, maps $1_{i-1}$ to $1_i$, otherwise.
- The arrow $y_i$ maps $1_i$ to $1_{i-1}$, if $i \in I$, maps $1_i$ to $1_{i-1}$ otherwise.

Remark 6.8. The module $L_I$ is free of rank $n$ over $Z(B)$. It is in fact Cohen-Macaulay of rank one, and all Cohen-Macaulay modules of rank one over $B$ are of this form for some $I$, by [JKS16].

Remark 6.9. By construction, we have canonical isomorphisms $^gL_I = L_{I-n_0}$, where $^gM$ denotes the twist of $M$ by $g$ in $\text{mod}(B)$.

Example 6.10. We recall how the modules $L_I$ can be visualised as lattice diagrams ([JKS16, Section 5]) by presenting $L_{127}$ for $\text{sym}_3(\mathcal{O})$ of Example 3.8 in Figure 16.

![Lattice Diagram](image)

**Figure 16.** The lattice diagram for the module $L_{127}$ for $n = 9$.

We want to find analogous modules as the rank 1 modules from Definition 6.7 for the algebra $B_G$. Let us write $t$ for the element $(\hat{e} \otimes 1)(t \otimes 1)(\hat{e} \otimes 1) \in B_G$. Let $[I]_{n_0}$ be an equivalence class of $k$-element subsets of $\{1, \ldots, n\}$ under the equivalence $\sim_{n_0}$ of $2^{\{1, \ldots, n\}}$ (these are labels of regions of orbifold diagrams, as introduced in Section 3).

Definition 6.11. Let $I$ be a $k$-subset of $\{1, 2, \ldots, n\}$ and let $[I]_{n_0}$ be its equivalence class, for $n = dn_0$. We define a $B_G$-module as follows. As a vector space, we define

$$L_{[I]_{n_0}} = \bigoplus_{i=0}^{d-1} \bigoplus_{l=0}^{n_0} C[t],$$

where we denote the identities of the above power series rings by $1_i^l$. It is enough to describe the action of the elements $e_i, x_i, y_i \in B_G$ on the elements $1_i^l$. Addition on the superscripts $l$ is always modulo $n_0$.

- The element $e_i$ maps $1_i^l$ to $1_i^{l+1}$.
- The arrow $x_i$ maps $1_i^{l+1}$ to $1_i^l$ if $1 + ln_0 \in I$, it maps $1_i^{l+1}$ to $t1_i^l$ if $1 + ln_0 \notin I$.
- The arrow $y_i$ maps $1_i^l$ to $1_i^{l+1}$ if $1 + ln_0 \notin I$, it maps $1_i^l$ to $t1_i^{l+1}$ if $1 + ln_0 \in I$.

For $i = \{2, \ldots, n_0\}$, the $x_i$ and $y_i$ act as follows:

- The arrow $x_i$, $i = \{2, \ldots, n_0\}$, maps $1_i^{l+1}$ to $1_i^l$ if $i + ln_0 \in I$, it maps $1_i^{l+1}$ to $t1_i^l$ if $i + ln_0 \notin I$.
- The arrow $y_i$, maps $1_i^l$ to $1_i^{l+1}$ if $i + ln_0 \notin I$, it maps $1_i^l$ to $t1_i^{l+1}$ if $i + ln_0 \in I$.

Observe that the definition of $L_{[I]_{n_0}}$ does indeed depend on the choice of $I \in [I]_{n_0}$, see Example 6.12 below. So this seems not well-defined at first sight. However, we will show in Lemma 6.14 that different choices of representatives for $[I]_{n_0}$ result in modules which are canonically isomorphic, cf. also Remarks 6.15 and 6.18.

Example 6.12. We illustrate Definition 6.11 on Example 3.8. Let $n_0 = d = 3$ and so $n = 9$. The quiver with potential of the above example is described in Example 4.11. Recall that $[147]_{3} = \{1, 4, 7\}$ because the corresponding alternating region contains the orbifold point. All other equivalence classes contain three 3-subsets of 9. In Figure 17 we give the modules $L_{[I]_{n_0}}$, $L_{[I]_{n_0}}$, for $I = \{1, 2, 7\}$ and $J = \{1, 4, 5\}$ as lattice diagrams (similarly as for the rank 1 modules for $B$ in [JKS16, Section 5]).
that $[127]_3 = [145]_3$. Figure 18 gives the top part of the three different modules $L_{[127]_3}$, $L_{[145]_3}$, and $L_{[478]_3}$ as lattices on the three columns for the three vertices of the algebra $B_G$, with the layers $l = 0, l = 1, l = 2$ in different colours. The vertices and arrows outside of the middle region are repeated as empty circles and dashed arrows to the left and right.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{modules.png}
\caption{On the left the module $L_{[127]_3}$ and on the right $L_{[145]_3}$.}
\end{figure}

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{layers.png}
\caption{The modules $L_{[127]_3}$, $L_{[145]_3}$ and $L_{[478]_3}$ with their layers coloured.}
\end{figure}

We define a $\mathbb{C}[\{t\}]$-linear map $\varphi$ from $L_{[I]_{n_0}}$ to $L_{[I+n_0]_{n_0}}$ where $I+n_0$ is the $k$-subset obtained from $I$ by adding $n_0$ to each element of $I$. The map $\varphi$ increases the label $l$ by $1$ modulo $d$, i.e. we set: $\varphi(1^l_j) = 1^{l+1}_j$ for $l < d - 1$ and $\varphi(1^d_j) = 1^0_j$.

We claim that this map $\varphi$ is a $B_G$-module homomorphism:

Remark 6.13. Let $I$ be a $k$-subset of $\{1, 2, \ldots, n\}$ and $[I]_{n_0}$ its equivalence class for $n = dn_0$. Note that $i + (l+1)n_0 \in I + n_0$ if and only if $i + ln_0 \in I$.

Lemma 6.14. Let $I$ be a $k$-subset of $\{1, 2, \ldots, n\}$ and $[I]_{n_0}$ its equivalence class for $n = dn_0$. The map $\varphi$ induces an isomorphism $L_{[I]_{n_0}} \cong L_{[I+n_0]_{n_0}}$ of $B_G$-modules.

Proof. First, we check $\varphi$ is a homomorphism of $B_G$-modules. To ease the notation, let $J = I + n_0$, and so by Remark 6.13, $i + ln_0 \in J$ if and only if $i + (l-1)n_0 \in I$ for any $i \in \{1, \ldots, n_0\}$, $l = 0, \ldots, d - 1$.

We have:

- For every $i \in \{1, \ldots, n_0\}$,

$$e_i \varphi(1^l_j) = \begin{cases} 1^{l+1}_j & \text{if } i = j; \\ 0 & \text{otherwise} \end{cases}$$

$$\varphi(e_i 1^l_j) = \begin{cases} \varphi(1^l_j) = 1^{l+1}_j & \text{if } i = j; \\ \varphi(0) = 0 & \text{if } i \neq j. \end{cases}$$
Since \( x_1 1_i^j = 0 \) unless \( j = n_0 \), it is enough to consider the effect of \( x_1 \) only on \( \varphi(1_{i\to}^{l-1}) \):
\[
 x_1 \varphi(1_{i\to}^{l-1}) = x_1 1_i^{l+1} = \begin{cases} 
 1_i^{l+1} & \text{if } 1 + l n_0 \notin J \\
 t_i^{l+1} & \text{if } 1 + l n_0 \in J
\end{cases}
\]
\[
= \begin{cases} 
 1_i^{l+1} & \text{if } 1 + (l - 1)n_0 \notin I \\
 t_i^{l+1} & \text{if } 1 + (l - 1)n_0 \in I
\end{cases}
= \varphi(x_1 1_i^{l-1}),
\]

• and the effect of \( y_1 \) on \( \varphi(1_i^{l-1}) \):
\[
y_1 \varphi(1_i^{l-1}) = y_1 1_i^{l+1} = \begin{cases} 
 1_i^{l+1} & \text{if } 1 + l n_0 \notin J \\
 t_i^{l+1} & \text{if } 1 + l n_0 \in J
\end{cases}
\]
\[
= \begin{cases} 
 1_i^{l+1} & \text{if } 1 + (l - 1)n_0 \notin I \\
 t_i^{l+1} & \text{if } 1 + (l - 1)n_0 \in I
\end{cases}
= \varphi(y_1 1_i^{l-1}).
\]

• For \( i \in \{2, \ldots, n_0\} \), the effect of \( x_i \) on \( \varphi(1_{i\to}^{l-1}) \) is:
\[
x_i \varphi(1_{i\to}^{l-1}) = x_i 1_i^{l+1} = \begin{cases} 
 1_i^{l+1} & \text{if } 1 + (l + 1)n_0 \notin J \\
 t_i^{l+1} & \text{if } 1 + (l + 1)n_0 \in J
\end{cases}
\]
\[
= \begin{cases} 
 1_i^{l+1} & \text{if } 1 + l n_0 \notin I \\
 t_i^{l+1} & \text{if } 1 + l n_0 \in I
\end{cases}
= \varphi(x_i 1_i^{l-1}).
\]

• For \( i \in \{2, \ldots, n_0\} \), the effect of \( y_i \) on \( \varphi(1_i^{l}) \) is:
\[
y_i \varphi(1_i^{l}) = y_i 1_i^{l+1} = \begin{cases} 
 1_i^{l+1} & \text{if } 1 + (l + 1)n_0 \notin J \\
 t_i^{l+1} & \text{if } 1 + (l + 1)n_0 \in J
\end{cases}
\]
\[
= \begin{cases} 
 1_i^{l+1} & \text{if } 1 + l n_0 \notin I \\
 t_i^{l+1} & \text{if } 1 + l n_0 \in I
\end{cases}
= \varphi(y_i 1_i^{l}).
\]

For the bijectivity, we note that \( \varphi \) permutes the generators of the modules and that the generators freely generate the modules over the centre. \( \square \)

**Remark 6.15.** By Lemma 6.14, the module \( L_{[t]_{l=0}} \) is well defined.

**Remark 6.16.** As we have mentioned, from the definition it is clear that \( x_i y_i \) maps \( 1_i^j \) to \( t_i^j \), so calling all the variables in the power series rings in Definition 6.11 \( t \) is justified.

We want to relate the \( B_G \)-modules \( L_{[t]_{l=0}} \) to the \( B \)-modules \( L_t \). For this, we need to introduce some notation. The map \( B \to B * G \) given by \( b \mapsto b \otimes 1 \) induces a functor \( F = (B * G) \otimes_B - \from \text{mod}(B) \to \text{mod}(B * G) \). There is an equivalence \( j^*: \text{mod}(B * G) \to \text{mod}(B_G) \) given by
\[
j^* = (\tilde{c} \otimes 1)B * G \otimes_{B_G} -
\]

using the isomorphism of Proposition 6.5 where \( \tilde{c} = e_1 + \cdots + e_{n_0} \) is the idempotent of the first \( n_0 \) vertices of \( \Pi_l \).

We aim to prove that \( L_{[t]_{l=0}} \cong j^* F(L_t) \). Let us do some preparation. As a \( B \)-module, \( (B * G) \otimes_B L_t \) is generated by the elements \( (1 \otimes g') \otimes_B 1_h \). This in turn implies that the \( B_G \)-module \( j^* F(L_t) \) is generated by elements of the form \( (e_i \otimes g') \otimes_B 1_h \). However, these elements are nonzero (if and only if \( h = g^{-1}(i) \)). We are left with considering the elements \( (e_i \otimes g') \otimes_B 1_{g^{-1}(i)} \), for \( i \in \{1, \ldots, n_0\} \) and \( l \in \{0, \ldots, d - 1\} \). Observe that \( t \) (which again we use as notation for \( (\tilde{c} \otimes 1)(l \otimes 1)(\tilde{c} \otimes 1) \)) as well as for \( \sum_{i=1}^{n_0} x_i y_i \) in the quiver description of \( B_G \) is in the center of \( B_G \), so that as a \( \mathbb{C}[l] \)-module we have a decomposition \( j^* F(L_t) = \bigoplus_{i=1}^{d-1} \bigoplus_{l=0}^{n_0} C[l][t] \). It is therefore natural to define a map of \( \mathbb{C}[l] \)-modules \( \psi: L_{[t]_{l=0}} \to j^* F(L_t) \) by setting
\[
\psi(1_i^{l}) = (e_i \otimes g^{-1}) \otimes_B 1_{g^{-1}(i)}.
\]

**Lemma 6.17.** The map \( \psi: L_{[t]_{l=0}} \to j^* F(L_t) \) is an isomorphism of \( B_G \)-modules.
Proof. The strategy is the same as in the proof of Lemma 6.14. First of all, \( \psi \) permutes the free generators of the corresponding modules, giving the bijection.

To see that \( \psi \) is a \( B_G \)-module homomorphism, we check that \( e_i, x_i, y_i \) in \( B_G \) act on \( 1^i_i \) in the same way as the corresponding elements in \( (\bar{e} \otimes 1)(B \ast G)(\bar{e} \otimes 1) \) act on \( (e_j \otimes g^{-j}) \otimes_B 1^j_{g^j(i)} \) by left multiplication. Note that \( g^j(j) = j + l_n0 \).

As before, for the action of \( x_i \), we will restrict to \( j = i - 1 \), for the action of \( y_i \) to \( j = i \).

We have:

- For every \( i \in \{1, \ldots, n_0\} \),
  \[
  (e_i \otimes 1)\psi(1^i_i) = (e_i \otimes 1)(e_j \otimes g^{-j}) \otimes_B 1^j_{g^j(i)}
  = (e_i e_j \otimes g^{-j}) \otimes_B 1^j_{g^j(i)}
  = \begin{cases} 
  (\psi(1^i_i)) & \text{if } i = j; \\
  0 & \text{otherwise}
  \end{cases}
  = \psi(e_i 1^i_i).
  \]

- For \( i \in \{2, \ldots, n_0\} \) (and \( j = i - 1 \)),
  \[
  (x_i \otimes 1)\psi(1^i_{i-1}) = (x_i \otimes 1)(e_{i-1} \otimes g^{-i}) \otimes_B 1^i_{g^i(i-1)}
  = (x_i \otimes g^{-i}) \otimes_B 1_{g^i(i)} + l_n0
  = (e_i \otimes g^{-i})(g^i(x_i) \otimes 1) \otimes_B 1_{g^i(i) + l_n0} \text{ (using Definition 5.1)}
  \]
  now \( g^i(x_i) \otimes 1 = x_i + l_n0 \otimes 1 \) is in \( B \) and we can pull it across \( \otimes_B \) to get
  \[
  = (e_i \otimes g^{-i}) \otimes_B \begin{cases} 
  1_{g^i(i) + l_n0} & \text{if } i + l_n0 \in I; \\
  t1_{g^i(i) + l_n0} & \text{if } i + l_n0 \notin I
  \end{cases}
  = \begin{cases} 
  \psi(1^i_i) & \text{if } i + l_n0 \in I; \\
  \psi(t1^i_i) & \text{if } i + l_n0 \notin I
  \end{cases}
  = \psi(x_i 1^i_{i-1}).
  \]

- For \( i \in \{2, \ldots, n_0\} \) (and \( j = i \)),
  \[
  (y_i \otimes 1)\psi(1^i_i) = (y_i \otimes 1)(e_{i-1} \otimes g^{-i}) \otimes_B 1^i_{g^i(i)} = (y_i \otimes g^{-i}) \otimes_B 1_{+l_n0}
  = (e_{i-1} \otimes g^{-i})(g^i(y_i) \otimes 1) \otimes_B 1_{+l_n0}
  = (e_{i-1} \otimes g^{-i}) \otimes_B \begin{cases} 
  1_{g^i(i) + l_n0} & \text{if } i + l_n0 \notin I; \\
  t1_{g^i(i) + l_n0} & \text{if } i + l_n0 \in I
  \end{cases}
  = \begin{cases} 
  \psi(1^i_{i-1}) & \text{if } i + l_n0 \notin I; \\
  \psi(t1^i_{i-1}) & \text{if } i + l_n0 \in I
  \end{cases}
  = \psi(y_i 1^i_i).
  \]

- Finally, for \( i = 1 \) and \( j = n_0 \), recalling that \( x_1 \in B_G \) maps to \( x_1 \otimes g^{-1} \in (\bar{e} \otimes 1)B \ast G(\bar{e} \otimes 1) \) via the isomorphism of Proposition 6.5,
  \[
  (x_1 \otimes g^{-1})\psi(1^1_{n_0}) = (x_1 \otimes g^{-1})(e_{n_0} \otimes g^{-i}) \otimes_B 1^{g^i(n_0)} = x_1 \otimes g^{-i-1} \otimes_B 1_{g^{i+1}(1) + l_n0}
  = (e_1 \otimes g^{-i-1})(g^i+1(x_1) \otimes 1) \otimes_B 1_{g^{i+1}(1) + l_n0}
  = (e_1 \otimes g^{-i-1}) \otimes_B x_{g^{i+1}(1)}(1) \otimes_B 1_{g^{i+1}(1) + l_n0}
  = (e_1 \otimes g^{-i-1}) \otimes_B \begin{cases} 
  1^{g^i+1(1)} & \text{if } 1 + (l + 1)n_0 \in I; \\
  t1^{g^i+1(1)} & \text{if } 1 + (l + 1)n_0 \notin I
  \end{cases}
  \]
  \[
  = \begin{cases} 
  \psi(1^{g^i+1(1)}) & \text{if } 1 + (l + 1)n_0 \in I; \\
  \psi(t1^{1^{g^i+1(1)}}) & \text{if } 1 + (l + 1)n_0 \notin I
  \end{cases}
  = \psi(x_1 1^i_{n_0}).
  \]
With the above notation, we have
\[
(y_{n_0+1} \otimes g)\psi(1_I^1) = (y_{n_0+1} \otimes g)(e_1 \otimes g^{-1}) \otimes_B 1_{g(1)} = (y_{n_0+1} \otimes g^{-1+1}) \otimes_B 1_{1+I_n_0}
\]
\[
= (e_{n_0} \otimes g^{-1+1})(g^{-1-1}(y_{n_0+1}) \otimes 1) \otimes_B 1_{1+I_n_0}
\]
\[
= (e_{n_0} \otimes g^{-1+1}) \otimes_B 1_{y_1+I_n_0,1+I_n_0}
\]
\[
= (e_{n_0} \otimes g^{-1+1}) \otimes_B \begin{cases} 1_{g^{-1}(n_0)} & \text{if } 1 + n_0 \not\in I \\ 1_{g^{-1}(n_0)} & \text{if } 1 + n_0 \in I \\ \psi(1_{I_n_0}^{-1}) & \text{if } 1 + n_0 \not\in I \\ \psi(1_{I_n_0}^{-1}) & \text{if } 1 + n_0 \in I \\ \psi(y_1 1^1). \end{cases}
\]

\[\square\]

Remark 6.18. Since \(F(M) = F(9M)\) for any \(M \in \text{mod}(B)\), we recover that the modules \(L_{[I]n_0}\) are well defined (cf. Remark 6.15).

Lemma 6.19. If \([I]n_0 \neq [J]n_0\) then \(L_{[I]n_0} \not\cong L_{[J]n_0}\).

Proof. Assume that \(L_{[I]n_0} \cong L_{[J]n_0}\). By Lemma 6.17, we have that \(j^*F(L_I) \cong j^*F(L_J)\) hence \(F(L_I) \cong F(L_J)\). This implies that \(L_I \cong gL_J\) for some \(g \in G\). We conclude that \(I\) and \(J\) differ by a multiple of \(n_0\) and so \([I]n_0 = [J]n_0\).

\[\square\]

Corollary 6.20. Let \(I\) and \(J\) be \(k\)-subsets of \(n = dn_0\). Then \(L_{[I]n_0} \cong L_{[J]n_0}\) if and only if \([I]n_0 = [J]n_0\).

6.2. The algebra \(A(\mathcal{O})\) as endomorphism algebra. Let now \(T_P\) be the \(B\)-module defined by

\[T_P = \bigoplus_{I \in \mathcal{O}} L_I.\]

Since \(\mathcal{P}\) is \(d\)-symmetric, it is invariant under rotation by \(n_0\) steps. It follows that \(T_P = gT_P\), since \(L_{I-n_0} = gL_I\). As the labels correspond to regions on the disk, they either come in orbits of length \(d\) (i.e. are acted upon freely by \(G\)) or are fixed, and there can be at most one fixed label (the label of the central region, if it is alternating).

Definition 6.21. Let \(\mathcal{O}\) be an orbifold diagram on a disk with \(n_0\) points. Let \(T_{\mathcal{O}}\) be the \(B_G\)-module defined by

\[T_{\mathcal{O}} = \bigoplus_{[I]n_0 \in \mathcal{T}_{\mathcal{O}}} L_{[I]n_0}.\]

We need some more notation. Let \(T_0 = L_I\) for the label \(I\) of the central region of \(\mathcal{P}\), if it is alternating, and \(T_0 = 0\) otherwise. The group \(G\) acts freely on \(T_P \setminus T_0\), and we call \(T_P\) a chosen cross-section of this action. Finally, we call \(T_{P,\text{red}} = T_0 \oplus T_P\).

Lemma 6.22. We have \(T_{\mathcal{O}} = j^*F(T_{P,\text{red}})\).

Proof. Use Lemma 6.17 and Definition 3.1.

\[\square\]

Theorem 6.23. With the above notation, we have \(A(\mathcal{O}) \cong \text{End}_{B_G}(T_{\mathcal{O}})\).

Proof. By Proposition 6.1, we know that \(A(\mathcal{O})\) is Morita equivalent to \(A(\mathcal{P}) \ast G\), where the action of a generator is given by rotating \(n_0 = \text{GCD}(k,n)\) steps clockwise. We recall the isomorphism \(A(\mathcal{P}) \cong \text{End}_B(T_P)\) from [BKM16, Section 10]. This isomorphism arises from sending every arrow \(a: I \to J\) in \(Q_P\) with \(I, J\) vertices of \(\mathcal{P}\) to the (injective) minimal codimension map \(L_I \to L_J\) (sending the lattice diagram of the module \(L_I\) as high up as possible into the lattice diagram of \(L_J\)). As \(\mathcal{P}\) is \(d\)-symmetric, if \(a: I \to J\) is an arrow between two vertices which do not correspond to the central region, it appears with \(d-1\) “rotated” copies: there are arrows \(a_m: I + m n_0 \to J + m n_0\) for \(m = 0, \ldots, d-1\) where \(a_0 = a\). Similarly, if \(I\) corresponds to the central region, there are arrows \(a_m: I \to J + m n_0\) for \(m = 0, \ldots, d-1\) or if \(J\) is at the central region, there are arrows \(a_m: I + m n_0 \to J\) for \(m = 0, \ldots, d-1\). With the action by twists on \(\text{End}_B(T_P)\) as in Section 6.1, the isomorphism \(A(\mathcal{P}) \cong \text{End}_B(T_P)\) is \(G\)-invariant. We get then an isomorphism \(A(\mathcal{P}) \ast G \cong \text{End}_B(T_P) \ast G\). Now we can apply Lemma 5.6 and Lemma 5.7 to \(M_0 \oplus M = T_P = T_0 \oplus F(T_P^*)\), so \(M_1 = T_P^\text{red}\).
We obtain a Morita equivalence
\[ \text{End}_B(T_P) \ast G \sim \text{End}_{\text{mod}(B)}(F(T_0) \oplus F(T_P)) = \text{End}_{\text{mod}(B)}(F(T_P^{\text{red}})) \]

The latter is in turn Morita equivalent to \( \text{End}_{B \ast G}(F(T_P^{\text{red}})) \) and then to \( \text{End}_{B \ast G}(j^* F(T_P^{\text{red}})) \), since both \( E \) and \( j^* \) are equivalences. Finally, by Lemma 6.22, the latter equals \( \text{End}_{B \ast G}(T_O) \). We have proved that \( A(O) \sim \text{End}_{B \ast G}(T_O) \). The statement follows since both algebras are basic (the latter by Lemma 6.19). □

**Remark 6.24.** We conclude with a remark motivated by the following question: in [BKM16], the dimer algebra \( A \) is shown to be isomorphic to the endomorphism algebra of a module \( T \), which is a cluster tilting object in a Frobenius, stably 2-Calabi-Yau category. Is the same true in our case? By results of Demonet ([Dem11, §2.2.4]), it is indeed the case that the skew group category \( \text{CM}(B) \ast G \) of the category of Cohen-Macaulay \( B \)-modules is Frobenius and stably 2-CY, and our module \( T_O \) does lie in it. Moreover, \( F \) maps \( G \)-invariant cluster tilting objects to cluster tilting objects, so indeed \( T_O \) is cluster tilting. We note however that we do not have a direct description of the category \( \text{CM}(B) \ast G \) as (equivalent to) a subcategory of \( \text{mod}(B \ast G) \).
